The recently published memoirs of Dr. Thomas Addis Emmet[3] are full of striking features illustrative of the medical professional life of the latter half of the nineteenth century in America, and reflecting the varied interests in life of a man who, though nearly 84 years of age, still retains the full vigor of his intellectual faculties. Dr. Emmet's is one of the comparatively few American names—and one of the earliest—that was well known in European medical circles practically half a century ago. Some of his work was that of a pioneer in the best sense of the word; it influenced the American medical profession widely, and yet was so thoroughly practical that it is still influencing us. It may be readily understood, therefore, how much such a volume from his pen means. Dr. Emmet's recollections are linked with many of the most important incidents in our medical history. For instance, he went through two awful epidemics of typhus fever with the Irish immigrants on Ward's Island in the early fifties. During the cholera epidemic of 1854, on two occasions, on making his visit to the immigrant hospital he found that all the patients and nurses in his ward had died of the disease since his previous visit. The relations of Emmet and Sims are also interesting; likewise the story of the origin of the Woman's Hospital and of the Cancer Hospital, now called the Memorial Hospital in New York.

One of Dr. Emmet's hobbies was the collection of documents relating to American history. He was one of the first in the field to gather autograph material, and he succeeded in making a collection unequaled of its kind. This is now in the Lenox Library, New York, bearing the name of the Kennedy-Emmet collection. Among autograph collectors, Dr. Emmet's name is known all over the world, while among American historians his work is considered most important for the saving of valuable material which would certainly have been lost but for his interest in it. It is probable that Dr. Emmet spent nearly a quarter of a million dollars in the making of this collection, which is now invaluable.

A sketch of the life of Sir William Hingston, a prominent surgeon and notable citizen of Montreal, who died four years ago, in his seventy-eighth year, appeared in the January number of the *American Catholic Quarterly*. Like Dr. Emmet, Sir William Hingston was a self-made man. He was the son of a widow in straitened circumstances, and carried on his medical studies while acting as assistant in a drugstore. Yet he succeeded in doing fine work in his subsequent career and attracted the attention of the conservative English-speaking profession, so that more than twenty-five years before his death he was asked to deliver the annual address on surgery before the British Medical Association. At its meeting in Canada, he was one of the honorary presidents and one of those selected for a knighthood on the occasion of Queen Victoria's jubilee. He served two successful terms as mayor of Montreal, became a life senator of Canada, and when he died a session of the Canadian senate was taken up with tributes to this member, who had begun life under such discouraging circumstances.

In Sir William's career there is abundant encouragement for the man who has to contend against difficulties in obtaining a professional training. The story of his two years in Europe just after graduation, when on less than $500 he succeeded in spending prolonged periods in Edinburgh, London, Paris and some of the German cities, getting in touch with the best surgeons in Europe and coming home thoroughly prepared to do good work, is of itself a typical example of his power to overcome what would seem to a less indomitable character impossible obstacles. But his efforts at self-education did not stop there. He became one of the busiest of Montreal's practitioners, occupied mainly with the poor; yet he succeeded in piecing out the fragments of a classical education that he had obtained in a single year at college into a fine classical scholarship. He knew French and German well, and had a thorough command of English, being both an effective orator and a ready writer.

Above all, he showed clearly that it is possible to combine the career of a successful, busy surgeon with that of a citizen who sees and performs his duty to the community. The lives of such men as Emmet and Hingston must prove a stimulus to high professional work and a deep sense of patriotic duty.

ANAPHYLAXIS

In a recent article, Friedberger[1] has reviewed our present knowledge of the subject of anaphylaxis. As a result of the great amount of work devoted to this phase of immunization, both in this country and abroad, it is now better understood, and is even being invoked to explain other more obscure phenomena of disease. According to our present conception, the process of anaphylaxis is in brief as follows: On the introduction of the first dose of a foreign proteid into an animal, there occurs a gradual increase of the antibodies for this substance—antibodies already present in small amounts normally. If, now, after a suitable interval, say from eight to ten days, a second dose be given, these antibodies, now present in increased quantities, produce a rapid disintegration of the proteid, with liberation of toxic products. If the animal survives this sudden liberation of poisonous material, farther cleavage of these products rapidly renders them innocuous.

---

[2] Hale, Worth: A Comparative Study of Digalen, The Journal A. M. A., Jan. 1, 1910, p. 35; The Comparative Strength of Digipuratum, Jan. 8, 1910, p. 129.

[3] Emmet, Thomas Addis: Incidents of My Life, Professional, Literary, Social, with Services in the Cause of Ireland, G. P. Putnam's Sons, New York, 1910.

[1] Friedberger: Deutsch. med. Wchnschr., 1911, xxxvii, 481.

Such a hypersensitization to foreign proteids is peculiar in that for the most part it is necessary to introduce them by some route other than the alimentary canal. When, however, we consider the great breaking up undergone in the process of digestion, it will be readily seen that any characteristic peculiar to a given proteid would ordinarily be so modified before absorption as completely to alter any toxic effect that it might possess. Indeed, the anaphylactic reaction is believed to be due to a splitting up of proteid into exactly the products it would yield in intestinal digestion; the poisonous intermediate products, however, which in the latter case would undergo still farther cleavage before entering the system, are in the former liberated directly into the blood-stream, and so are free to exert their toxic action. In support of this view is the fact that in those cases in which there is excessive antibody formation, the acute anaphylactic reaction is diminished or absent; the probable explanation being that the breaking up of the proteid into its ultimate constituents is so rapid as to prevent the accumulation of toxic intermediate products in quantities sufficient to do harm. Idiosyncrasy to articles of food is to be explained, on this basis, by the absorption of sufficient unmodified proteid to react with antibodies already present, either congenitally or formed under similar previous conditions.

In addition to the "active" anaphylaxis, produced by the direct administration of sensitizing doses of proteid to the animal organism, it is possible to produce "passive anaphylaxis" by transferring hypersensibility to other animals with the serum of treated animals. This so-called passive anaphylaxis belongs in the same class as passive immunization. Further analogy is shown by the necessity of free complement to produce the reaction. If an animal be given its second dose of proteid, in nonlethal amount, at an interval greater than the ten days at which hypersensitization reaches its height, the excess of antibodies present becomes bound, and the animal becomes relatively free from farther reaction. This is the so-called anti-anaphylaxis.

According to the views of Ehrlich, all antibodies are merely the result of the increase of substances already present in the normal animal; and in accordance with this view is the fact that the introduction of a sufficient quantity of foreign proteid into a perfectly normal animal will produce toxic effects. If, however, care be taken to give it in a quantity insufficient to cause death, the antibodies normally present will cause a relatively slow production of the toxic intermediate products, and at the same time formation of both the cleavage products and the antibodies evoked by the injection will take place. If now this serum be transferred to a second normal animal, acute poisoning will intervene—the so-called antiserum-anaphylaxis. The explanation probably lies in the fact that in the second animal there is already present a certain amount of antibody, which, in conjunction with the amount present in the injected serum, is sufficient to produce acute anaphylaxis.

By far the most interesting of the recent developments of this subject are the relations that are being established between anaphylaxis and many infections, both acute and chronic. It is becoming generally accepted that many of the processes which formerly we were wont to ascribe purely to specific toxins are more properly to be considered as due to the interaction of bacterial proteid and antibodies already present, or formed during the infection, in the host. This phase of the subject, however, has been recently taken up in these columns,[2] and need not be discussed further at this time.

Current Comment

SOME PROBLEMS OF SCHOOL INSPECTION

While school inspection has been the subject of much commendatory mention in the public press, some objections have been raised to proposed legislation making it compulsory. The question has been raised as to the propriety of complete examinations requiring exposures of the chest, etc., especially in the older girls, it being urged that parents should be allowed to select the physician to make the examination. As perhaps might have been expected, the sectarian schools of medicine have been more or less to the fore in the objections. This trouble has been encountered in Newark, N. J., where, for instance, examination of the heart and lungs has been insisted on as a feature of school inspection. It is natural that the inspecting authorities should want to forestall criticisms as to the thoroughness of their work, which would be very liable to be made by those not in full sympathy with the movement. It would seem, however, that since the school has no interest in heart disease further than as it affects the functional capacity of the heart, such tests as are necessary might be made without requiring any exposure which would be offensive to the pupils and resented by their parents. It would doubtless be well for those engaged in the work to remember that medical school inspection is at present on trial so far as the general public is concerned, and that lack of tact may prejudice the cause as much as lack of skill, if not more. It is not desirable that medical school inspectors shall be time-servers; but for a school physician to strain his brief authority by too arbitrary insistence on methods of inspection which parents have not learned to regard as a matter of course in private practice, would seem to be premature, to say the least. Doubtless, with greater experience, by the exercise of tact, by educating the public and winning its confidence, inspectors will be able in most instances to secure all needed information and at the same time to avoid any occasion for conflict between the authority of the home and that of the school. This is always disastrous, and would be especially regrettable just now in the case of medical school inspection.

MONEY FOR MEDICAL EDUCATION

After a long season of neglect it seems that medical education is coming into its own in regard to financial support. Such benefactions as the recent gift of $200,000 from Dr. and Mrs. Robert W. Long of Indianapolis, toward the establishment of a teaching hospital for the Indiana University School of Medicine, indicate an increase of interest in the cause; and not only are private donors making generous contributions, but legislatures also are making more liberal appropriations for the support of their state university medical schools. Word has just been received that in Alabama $100,000 has been appropriated for the support of the medical school of the state university for the next four years; and from Nebraska comes the news that a like sum has been appropriated to establish all four years of the University of Nebraska College of Medicine on the new campus in Omaha. A smaller but no less important appropriation was that of $30,000 by the Oregon legislature which has made possible a closer relationship between the University of Oregon and its medical department—a relationship which heretofore has been largely nominal. Thus from all sections of the country come tidings of substantial gifts or appropriations for medical teaching institutions that represent the higher standards of medical education. These appropriations give much encouragement to those who have been working for the development of higher standards and lead one to believe that even more liberal appropriations will be made in the future. Surely no state could make a better investment than that which will secure better-trained physicians who are to be responsible for the preservation of the health and, therefore, of the happiness, of that commonwealth.

PROF. THEOBALD SMITH AS EXCHANGE PROFESSOR

Prof. Theobald Smith, Fabyan professor of comparative pathology at Harvard, has been appointed exchange professor for 1911-12 at Berlin University, following a plan inaugurated several years ago for the exchange of educators between the universities of Germany and the United States. This is not the first instance in which Harvard has been drawn on for the exchange professorships, but previously they have been from the faculty of arts and sciences. The drafting of Professor Smith is not only a recognition of the medical department of Harvard, but a high and well-deserved compliment to Professor Smith, who has attained eminence not only as an instructor and for his research work, but also on account of his public scientific services. He was at one time director of the pathologic laboratory of the national Department of Agriculture, and was for ten years professor of bacteriology at Columbian University, Washington, D. C. He was also director of the pathologic laboratory of the Massachusetts State Board of Health, and three years ago was awarded the gold medal of the Liverpool Society for the Study of Tropical Diseases for his studies of Texas fever. He is also known for his studies on metabolism. Professor Smith holds the degree of Ph.B., Cornell, 1881; M.D., Albany Medical College, 1883; honorary degree of A.M., Harvard, 1901; and the degree of S.D. from Harvard in 1910. In 1907 Chicago University gave him the degree of LL.D. The growing recognition abroad of the authority of the New World in medicine will be further advanced by the selection of Professor Smith, who is a worthy representative of the profession of scientific medicine.

A NEW OWEN BILL

Senator Owen has introduced a new department of health bill[1] which appears on the calendar of the sixty-second congress as Senate Bill 1. This bill is an elaboration of S. 6049 introduced by Senator Owen in the sixty-first congress, and has been modified to meet the objections raised against that measure. The principal criticisms, in fact the only ones brought out in the hearings on public health before the house and senate committees, were that there was a possibility of the functions of the state boards of health being infringed on; that the individual liberties of the people might possibly be impaired and that in organizing and administering the federal department of health there might be discrimination against some schools or sects of medicine. All of these objections were based on conjecture rather than fact, were of remote possibility and abundantly guarded against by existing laws and decisions. But in order to remove any possible grounds of objection to the bill, Senator Owen has specifically provided in the present bill that "this act shall not be construed as attempting to authorize the department of health to exercise or to attempt to exercise, without express invitation from the chief executive or other proper authority of the state, any function belonging exclusively to such state, or to enter any premises in any state without the consent of the owner or occupant thereof . . . and provided further that the department of health shall recognize no so-called school or system of medicine." These provisos should amply reassure the sincere opponents of Senator Owen's first bill who may have feared honestly, even though mistakenly, that an intelligent effort on the part of the federal government to investigate the causes of disease and to conserve the lives and health of the people might infringe on his personal rights. Such objectors have, of course, entirely failed to discriminate between the investigation of disease in the abstract and the treatment by individual physicians of individual patients. The former is a perfectly proper function of the federal government which can be exercised without affecting the rights of the individual in the slightest; the latter is and must always remain a personal prerogative, except under a form of government so socialistic in character as to be practically out of the question under existing conditions. Although the new bill explicitly removes all the honest objections which were raised to the old bill, it is not to be expected that these changes will allay the opposition to the measure, on the part of mercenary interests arrayed against further health legislation. Those familiar with the situation know that the sincere, but mistaken, objectors to the first Owen bill were only puppets in the hands of the mercenary interests which feared, and still fear, federal investigation of their business or interference with their ill-gotten profits. It is to be expected that these chronic objectors (for revenue only) will find new and equally far-fetched reasons for objecting to Senator Owen's latest bill. The public, however, will not be slow to detect the reasons for further opposition to a measure distinctively altruistic in character and for the benefit of the public. The bill provides for a department of health with a director at the head; for a subordinate commissioner of health and for the transfer of the Public Health and Marine-Hospital Service from the Treasury Department, the Bureau of Chemistry from the Department of Agriculture and the Division of Vital Statistics from the Department of Commerce and Labor. It also provides for bureaus of sanitary research, child hygiene, vital statistics and publication, food and drugs, quarantine, sanitary engineering, government hospitals and personnel and accounts. Cooperation with the health authorities of any state, as well as conferences of state health officers are also provided for. No provision is made for increased pay for the Marine-Hospital surgeons, as it is generally understood that a separate personnel bill will be introduced. Senator Owen's new bill marks a distinct advance in the development of a law to establish an effective federal department of health.

"APPLIED ETHICS IN JOURNALISM"

Under the above title, Theodore Roosevelt in the *Outlook* for April 15, makes some interesting comments regarding the "patent medicine" evil in its relation to the newspapers. After touching briefly on the fraud and cruelty connected with fake financial advertising, Mr. Roosevelt says:

> The patent medicine advertising represents as great an evil . . . We hear much of the influence exercised by great corporations on the press, and unquestionably this influence has been and is, very serious. Yet it cannot be greater than the evil influence exercised by the backers of objectionable medical and financial advertisements when they spend between thirty and forty millions a year in the daily newspaper press.

After thus speaking of the matter in the abstract, Mr. Roosevelt, as is his wont, comes down to the concrete by calling attention to some of the reasons why this form of fraud on the part of the newspapers is not more often fought. The New York *Herald* until 1907 carried without let or hindrance, in what was called the "Personal Columns," but which should have been designated "Abortionist Columns," advertisements that were both criminal and obscene. In that year, however, the Medical Society of the County of New York found a United States district attorney with sufficient courage to attack this cesspool of filth with the result that a verdict was secured against the proprietor of the *Herald* and he was forced to pay a fine of $25,000. Of the attitude taken by other newspapers regarding this case, Mr. Roosevelt says:

> In this case, by the way, many of the newspapers which are ordinarily of reasonable virtue so hid the facts as to prevent any effective understanding by the public of the real reason for the animosity very naturally shown by Mr. Bennett [proprietor of the *Herald*] through his papers ever since toward all the public officials who were in any way connected with bringing him to justice for his crime.

It is also worth while to call attention, at this time, to the fact that the *Herald*, ever since the "Personal Column" episode, has done its best to vilify and blackguard the medical profession, this, presumably, because its proprietor resents not only the loss of actual cash for payment of the fine, but also the still greater loss of revenue from the abortion advertisers whose "copy" became unacceptable in the eyes of the United States post-office authorities. The *Herald* was one of the first, if indeed it was not the first, of the New York papers to espouse the cause of the "patent medicine" interests' latest organization for fighting the American Medical Association—the National League for Medical Freedom.

Our ex-president also calls attention to the appalling number of "patent medicine" and quack advertisements that appear in the New York *World* and in the "World Almanac" for 1911 and then says:

> A peculiarly objectionable feature of these medical advertisements, exactly as with the financial advertisements, is that it is the poorest class, the most helpless class, of people that are most hurt by them. I believe that legislation could be framed to forbid such advertisements. In default of such legislation there is at least need that we should discriminate in the sharpest way between newspapers which war against this evil and newspapers which encourage it.

On the other hand, Mr. Roosevelt has expressed the greatest admiration for publications, such as *Collier's Weekly*, which have rendered the public a great service by exposing the viciousness and fraudulence of quackery and the "patent medicine" business. His excellent editorial closes as follows:

> We owe hearty respect to the public servant who, like ex-District Attorney Stimson, fearlessly does his duty in bringing to justice a great newspaper that goes wrong, although he knows that his action will be of harm to himself personally; and we are bound to pay a tribute of deserved respect to a paper like *Collier's* when, in a matter so vital to the public well-being, it wages so fearless, aggressive and efficient a fight for honesty and decency.

FOUNDED ON FALSEHOOD

There is at present before the United States Supreme Court a case, the decision in which will either wonderfully strengthen or irrevocably weaken the federal Food and Drugs Act. O. A. Johnson, a mail-order cancer-cure quack of Kansas City, Mo., shipped some of his nostrums in interstate commerce. The labels on these preparations bore the statement that they would cure cancer. As every physician knows, and as a large proportion of intelligent laymen know, this statement is an untruth. The government brought suit, under the Food and Drugs Act, declaring Johnson's nostrums misbranded in that the statements on the labels were false. Johnson fought the case, and it has finally reached the Supreme Court of the United States. He insists that the Food and Drugs Act was intended by Congress only to deal with the composition of medicines and not with their therapeutic value. When the case was being argued two or three days ago before the justices of the Supreme Court, Solicitor-General Lehmann maintained that, in drawing up the Food and Drugs Act, Congress recognized that it was just as important to deal with the curative effects of medicines as with their ingredients. Justice Lurton interrupted the Solicitor-General by asking whether such an interpretation of the law as the government desires "would not break up the patent-medicine business." Mr. Lehmann replied: "It probably would, and I know of nothing within the scope of Congress that would be more beneficial." The question by the justice and the answer by the solicitor-general are worth pondering over. Men who have reached the positions held by Solicitor-General Lehmann and Justice Lurton cannot, truthfully, be accused of being fanatics or prone to making radical statements. On the contrary they are likely to be, if anything, ultraconservative. Nevertheless, one of these men plainly intimates and the other frankly says that the "patent medicine" business is based on fraud and deceit. No other interpretation of the question and answer seems possible. Justice Lurton asks whether, if the "patent medicine" makers have to tell the truth about their products, it would not destroy their business; Solicitor-General Lehmann says that it would!

Medical News

CALIFORNIA

Personal.—Dr. Emil O. Jellinek, San Francisco, has gone abroad.——Dr. Norman D. Morrison, San Mateo, has been elected trustee of the San Mateo Union High School District.

Society Meeting.—Long Beach Medical Society, at its annual meeting, April 7, elected Dr. William H. Newman, president; Dr. Francis L. Rogers, secretary-treasurer; Dr. Albert C. Sellery, councilor. A committee composed of Drs. Albert C. Sellery, William H. Jones and Theophilus C. Donnell was appointed to arrange for the entertainment of the delegates of the American Medical Association.

Arequipa Sanatorium.—A *sanatorium* for the treatment of incipient cases of tuberculosis is assured to San Francisco by the gift of a tract of 40 acres of land near Fairfax, Marin County, by *Henry Bothin. Plans* for the structure have been made, and $5.000 has thus far been subscribed for the erection of the building. The entire cost of the institution will be about $20.000. Dr. Philip King Brown, San Francisco, is to be director of the sanatorium and the medical board will include Drs. Louis P. Howe, Richard G. Broderick and Lewis S. Mace, all of San Francisco. The institution is to be known as Arequipa, an Indian term meaning a place of rest.

CONNECTICUT

County Physicians Hold Meeting.—The one hundred and nineteenth annual meeting of the Hartford County Medical Association was held in Hartford, April 4. The following officers were elected: president, Dr. Harmon G. Howe, Hartford; vice-president, Dr. Henry A. Deane, South Windsor; secretary-treasurer, Dr. Paul P. Swett, Hartford; councilor, Dr. Oliver C. Smith, Hartford; censor, Dr. Frederick B. Willard, Hartford; delegates to the state society, Drs. Charles M. Wooster, Tariffville; Myron P. Robinson, Windsor Locks; Thomas G. Sloan, South Manchester; Paul P. Swett, *Hartford*; William R. Miller, Southington; John F. Dowling, Hartford, and Frank L. Waite, Hartford.

ILLINOIS

State Takes Over County Institutions.—By the terms of an agreement ratified April 12 by the house committee on appropriations, it is agreed to place on the omnibus appropriation bill an *item of* $450.000 to care for the ordinary and extraordinary expenses of Cook County Institutions, Dunning, until July 1, 1913.

Personal.—Dr. Emery W. Goembel, Rockford, who was operated on for appendicitis, April 10, is reported to be well on the road to recovery.——Dr. James A. Rutledge, Elgin, has been appointed medical director of the Modern Woodmen sanatorium, Colorado Springs.——Dr. Willis G. Hatch, Rockford, fractured his arm above the wrist while cranking his automobile, April 2.——Dr. Jacob S. Kauffman, Blue Island, has been appointed a member of the consulting staff of Oak Forest Infirmary.

State Alienists Organize.—The members of the medical staffs of the various state hospitals held a meeting in Elgin, April 12 and 13, and organized the Illinois State Hospitals Medical Society, and elected the following officers: Dr. H. Douglas Singer, Kankakee State Hospital, president; Dr. Charles F. Read, Watertown State Hospital, vice-president; and Dr. Ralph T. Hinton, Jacksonville State Hospital, secretary-treasurer. The object of the society is to study diseases of the insane, epileptics and other classes of unfortunates who are inmates of state institutions.

Recent State Board Cases.—In the case of the people versus Madame Florencia A. T. Powella, M.C.S., a "bloodless medical surgeon chiropodist," the defendant was tried before a jury in the municipal court for practicing medicine without a license, was fined $100 and costs. After a motion for a new trial had been overruled she appealed her case.——The State Board also prosecuted "Prof." J. C. Fisher, who was found guilty and fined $100 and costs for practicing medicine without a license. This individual is said to have had an altar in his front room before which patients were brought. The "Professor" murmured in front of the altar and finally turned and stated the nature of the ailment. He then rubbed the neck and temple of the patient, gave him medicine and charged him $2.

Antituberculosis Laboratory.—The latest donation of James A. Patton, Evanston, is that of half a million dollars to be devoted to the cause of medical reseach regarding tuberculosis. This donation is to be used to establish a laboratory in connection with Northwestern University Medical School which will band all its energies in the search for a cure for tuberculosis. Mr. Patton's original gift of $200,000 will be devoted to the establishment of a new chair in the medical school to be known as the chair of experimental or research medicine. The entire time of the professor in charge of this *department* will be given to investigation along lines indicated, and the work of the department will be in reciprocity with the other laboratories of the school. Four recent graduates will be paid a living salary, and will be induced to remain a year or longer in the laboratory before engaging in practice. In this way a school of investigation will be established, and the abler men will be induced to remain to engage in research work. Dr. Arthur R. Edwards, dean of the school, has been selected as head of this movement.

Chicago

Small-Pox.—During the week ended April 15, fourteen cases of small-pox were sent to the Isolation Hospital. Of these three were imported, thirteen had never been vaccinated, and the other one had an imperfect doubtful scar made in childhood. Five cases were taken to the hospital from one family. The physician in this case pronounced the disease chicken-pox and failed to report the case to the department of health.

Personal.—Dr. John B. Murphy, who has been ill with typhoid fever, is convalescent.——Dr. E. Fletcher Ingals is ill with typhoid fever but is reported to be doing well.——Dr. Eugene S. Talbot has been ill for several days with pneumonia, but is reported to be in good condition.——Dr. Clara Ferguson has been appointed a member of the medical staff of Cook County Hospital.——Drs. Hugh N. MacKechnie, *John A.* Graham, George N. Pratt, Frank J. Fara and Douglas A. Payne have been appointed members of the consulting medical staff of Oak Forest Infirmary.——Dr. Willis O. Nance was elected alderman at the recent election.

Dr. Evans' Valedictory.—On retiring from the office of health commissioner of Chicago, Dr. William A. Evans makes the following statement to the public in the *Weekly Bulletin:*

> When, in 1907, I assumed responsibility for the health department, I wrote that the work had been evolving; my predecessors had brought it up to a certain point and that I would try to build still further I think that the reputation of the department throughout the world, the growth of the older activities of the department and development of new activities, the greater security of the people and a better food and air supply, and a greater public interest in health, are further steps in that evolution. Perhaps most significant of all, the department is incorporated as, and in truth is, a school of sanitary instruction. Here, too, there is evolution, since the nucleus of it was this bulletin, begun by Drs. Reynolds and Reilly. I am steadfast in the hope and I assure the public of my belief that my successor will continue this evolution, fighting off the few in the interest of the great, needful mass.

And now I wish to say in sincerity that the results accomplished have been due to the brains, energy and faith of the men in charge of bureaus, and the men and women under them; to the vision and the courage of the mayor; to the cooperation of other departments of the city government; to the city council, which has passed every important ordinance asked of it, save one—that requiring that milk should be kept cold.

KANSAS

Opposes Contract Practice.—Shawnee County Medical Society, at its April meeting, adopted an amendment providing for the expulsion of any member of the society proved to have engaged in lodge or club practice.

LOUISIANA

Lumber Company will Operate Hospital.—Beginning with April 1, the Bogalusa Hospital is being operated directly by the Great Southern Lumber Company. Dr. Herbert C. Cole has been made chief surgeon of the institution.

Parish Election.—Calcasieu Parish Medical Society, at its annual meeting, at Lake Charles, April 4, elected Dr. Allen J. Perkins, Lake Charles, president; Dr. Hugh L. Sanders, West Lake, vice-president; Dr. Samuel George Kreeger, Lake Charles, secretary-treasurer (reelected), Dr. Edward R. Gandy, West Lake, delegate to the state society, and Dr. Norman S. Craig, Jennings, alternate.

New Home of Parish Society.—The new home of the Orleans Parish Medical Society, New Orleans, was dedicated with fitting ceremonies, March 13. The principal address of the evening was delivered by Dr. Stanford E. Chaillé on "The Organization of the Louisiana State and Orleans Parish Medical Societies." On March 27, the newly elected officers were installed, including Dr. Benjamin A. Ledbetter, president; Drs. Eugene H. Walet and Charles N. Chavigny, vice-president; Dr. Lawrence R. DeBuys, secretary; Dr. William H. Block, treasurer; Dr. Homer Dupuy, librarian, and Drs. Joseph T. De Grange, Arthur Nolte and William H. Seemann, directors.

MARYLAND

The State Sanatorium.—Plans for the new hospital buildings in connection with the Maryland State Tuberculosis Sanatorium, Sabillasville, have been finished. A new administration building is to be erected and also additional wings will be built, which will increase the capacity of the institution to 200.

Annual Meeting of Ladies' Auxiliary.—The Ladies' Auxiliary of the Widows' and Orphans' Fund, Medical and Chirurgical Faculty of Maryland, held its annual meeting in Baltimore, April 11. The following officers were elected: president, Mrs. William G. Gombel; vice-presidents, Mrs. Albert H. A. Mayer and Mrs. John G. Jeffers; recording secretary, Mrs. L. K. Michael; corresponding secretary, Mrs. Charles H. Bubert; treasurer, Mrs. Marshall L. Price, and executive committee, the officers and Mrs. James F. H. Gorsuch, Mrs. T. Casper Gilchrist, Mrs. William E. Wiegand and Mrs. George L. Duane.

Personal.—Dr. Warren P. Morrill, M. C. N. G., Md., Baltimore, has been detailed to take part in the maneuvers at San Antonio, Tex.——Dr. Thomas J. Coonan, Westminster, has been elected chairman of the Democratic State Central Committee for Carroll County.——Dr. R. A. Shankwiler, formerly resident physician at Eudowood Hospital for Tuberculosis, has been made superintendent of the Detroit Tuberculosis Sanatorium.——The emperor of Germany has conferred the order of the crown, second class, on Dr. William H. Welch, Baltimore, in appreciation of his services in propagating German medical science in the United States and in spreading the use of the German language in the medical schools of America.

MASSACHUSETTS

Boston Reappointments.—Dr. Samuel H. Durgin has been reappointed chairman of the board of health; Dr. Nathaniel W. Emerson, a trustee of the infirmary department, and Dr. Miles Martin, overseer of the poor.

The State Society Meeting.—The annual meeting of the Massachusetts Medical Society will be held in Boston, June 13 and 14. Two meetings of each section will be held the first day, and the section on tuberculosis will be held on the afternoon of that day. One of the sessions of the medical section will be devoted to a symposium on syphilis. The councilors' meeting will be held at noon on Tuesday and the Cotting lunch will be served as usual. The section meetings and the meeting of the council will be held at the Harvard Medical School. School buildings and laboratories will be open to the society and special scientific exhibits or exhibits illustrating papers of interest to members will be given in the laboratories. The Shattuck lecture and reception will be held as usual on Tuesday evening in the medical library. The annual meeting and discourse will be held on Wednesday at the medical school, after which the annual dinner will be served at Symphony Hall. Immediately after the dinner the society will adjourn to the Country Club to witness the annual inter-district baseball game.

MISSOURI.

Additional Accommodation in Tuberculosis Pavilion.—Through the efforts of the local antituberculosis society, six beds have been added to the pavilion for tuberculosis patients at the Kansas City General Hospital, making the total capacity twenty-two beds.

Colored Physicians to Work Among Their Race.—At the request of Dr. Walter S. Wheeler, health commissioner of Kansas City, the hospital and health board have approved the assignment of two colored physicians, Drs. Charles F. Clark and Lloyd E. Bailer, who will be assigned to look after colored charges in the city.

St. Louis

Intern Examination Held.—As the result of the competitive examinations for interns for the City Hospital, St. Louis University medical students obtained twenty-seven places and Washington University seventeen.

Personal.—Dr. Henry S. Atkins, superintendent of the Municipal Tuberculosis Sanatorium, has resigned.——Dr. Arthur H. Sewing, first resident physician at the City Hospital, has been appointed resident physician, vice Dr. Walter R. Hewitt, resigned.——Dr. H. Wheeler Bond, health commissioner, has sent to the comptroller a check for $1,799.18, representing the difference between the amount received as fees for registering vital statistics under the state law and the expense of conducting the office.

NEW HAMPSHIRE

Medical School Commencement.—The one hundred and thirteenth graduation exercises of Dartmouth Medical School, Hanover, were held, March 28, in College Hall. Dr. John M. Gile delivered the address to the graduating class, and President Ernest F. Nichols conferred degrees on a class of nine.

County Medical Society Election.—At the sixth annual meeting of the Hillsboro County Medical Society, held in Nashua, April 4, the following officers were elected: president, Dr Herbert L. Smith, Nashua; vice-president, Dr. James B. Pettingill, Amherst; secretary-treasurer, Dr. Ella B. Atherton, Nashua (reelected); auditor, Dr. Bradford Allen, Nashua, and delegate to the state society, Dr. Walter H. Abbott, Hillsboro.

National Guard Appointments.—At the recent meeting of the governor's council, the following nominations were made to fill vacancies in the medical department of the New Hampshire National Guard: Captain Russell Wilkins, Concord, promoted to major; Lieutenant Bertell L. Talbot, Peterboro, made captain, vice Dr. Wilkins, promoted; Dr. Robert J. Graves, Concord, commissioned first lieutenant, vice Dr. Talbot promoted, and Dr. Charles S. Walker, Keene, first lieutenant, vice Dr. Jesse B. Hyland, Keene, resigned.

NEW YORK

Sanitarium for Dunkirk.—Plans have been completed for a sanitarium to be built at Cobb Mineral Springs, Dunkirk, to cost $15,000, to accommodate thirty patients and be completed July 1.

Matteawan Investigation.—Dr. Austin Flint, Dr. Carlos F. MacDonald and Goodwin Brown, who were named by Governor Dix to investigate conditions at the Matteawan State Hospital, have begun their work. They will question each one of the 897 patients as to food, treatment and other conditions. It is expected that the investigation will require several weeks.

Rabies in Yonkers.—Information has come from the New York City Health Department that during the last two months thirteen persons have received treatment for mad dog bites. A representative of the health department has advised instant cooperation with the state authorities. All dogs have been barred from the streets for sixty days unless muzzled or on a leash.

County Society Meeting.—At the quarterly meeting of the Oneida County Medical Society, held in Utica, April 10, communications were read from three physicians who were expelled from the society a year ago for violating the principles of ethics by advertising certain cures, giving notice that they intended to appeal to the state medical society from the decision of the county society. A general discussion was held on contract practice and a committee was appointed to confer and report on the matter.

New York City

Addition to Sloane Maternity Hospital.—Plans have been filed for the building of four additional stories on the Sloane Maternity Hospital for private patients. The cost of this addition will be about $60,000.

Cancer Home Asks Aid.—St. Rosa's Home devoted to the care of victims of incurable cancer is making an earnest effort to complete a fund of $50,000 to be used in the erection of a new building. The building fund at present amounts to $8.142.

New Step in the Antituberculosis Movement.—Babies may be seen in Central Park wearing the admonition "Please do not kiss me. I do not like it. It is harmful." It is hoped that this will assist in limiting other diseases besides tuberculosis.

Vacancy in Clinic.—Washington Heights Hospital announces vacancies in the medical and surgical clinic of the institution, Tuesday, Thursday and Saturday from 2 to 4 p. m. Application should be made to Dr. Louis Neuwelt, 2424 Seventh Avenue, New York City.

Medical Staff Resigns.—The entire medical staff of St. John's Hospital. Long Island City. is said to have resigned. The reason is said to be the objection of the members of the staff to the rules governing the institution. The 750 patients in the institution are being cared for by the visiting staff.

Against Bronx Hospital.—The State Board of Charities has disapproved of the incorporation of the Bronx Hospital which Manhattan physicians have been anxious to establish in the Bronx, but which was opposed by physicians in that locality. The Bronx physicians stated that they had a plan of their own on foot to start a hospital and they regarded the efforts of the Manhattan physicians as an encroachment on their territory.

Ships Bring Disease.—The death of two passengers on the Greek steamship *Themistocles* and of two on the Fabre liner *Germania*, from cerebrospinal meningitis, have caused the detention of the passengers in quarantine as precautionary measures.——Two cases of spinal meningitis were discovered among passengers on the Fabre liner *Venezia*, on its arrival in New York, March 29.——The steamer *Verona*, which arrived from Italy, March 31, was detained in quarantine on account of a case of small-pox among cabin passengers.

The Milk-Supply of New York City.—Commissioner Lederle, in an address before the International Pure Milk League, outlined the work of the department in its effort to secure pure milk. He stated that arrangements had been completed for the opening of fifteen milk stations. The health department will furnish physicians, nurses, milk inspectors and ice-boxes but will not handle the milk. They asked dealers to bid for the privilege of furnishing the milk. They have decided that for the present they will not pasteurize the milk but will instruct the mothers in the modification in their homes. The greatest problem that confronts the health department is the 14,000 little stores where milk is sold in small quantities.

Health Department Bulletins.—Recent bulletins of the department of health of New York City refer to the public control of venereal diseases in the city, recommending the early adoption of the plan of the sanitary control of such diseases; announces the passage of a resolution requesting the board of aldermen to approve of the issue of special revenue bonds to the amount of $10.000 for the purchase of food supplies for patients at the two day-camps maintained by the department on the ferry boats *Middletown* and *Susquehanna*, as these camps are among the most effective agencies in the extension of relief to the tuberculous poor, and in the campaign for the prevention of tuberculosis. The bulletin of April 7 gives a report of the work of the division of food inspection, showing the arrest of four candy dealers for violation of the sanitary code, and of one fruit dealer who sold decayed fruit, and the condemnation of 4,617 pounds of foodstuff on April 5. The succeeding bulletin announces that twenty-five arrests had been made on the upper East Side for the exposure of foodstuff and for offering decayed food for sale in violation of the provisions of the sanitary code. Twenty-two of the accused were found guilty and fined. The resolution of the board of health on the sanitary control of venereal disease for the protection of public health has been endorsed and approved by the New York Urological Society. The bulletin of April 10 is devoted to diarrheal diseases of infants under one year of age. During the first three months of 1911, there were 508 deaths of children from this cause in Greater New York as compared with 348 during the corresponding period of 1910. This increase has taken place almost entirely in institutions and hospitals where children are cared for. This is accounted for by the fact that the bulk of these deaths occurred in the New York Foundling Hospital where abandoned children, who are generally of low vitality, are received and cared for. The bulletin of April 11 deals with the spitting nuisance, and shows that during the first quarter of 1911, 434 arrests were made, 279 fines were imposed amounting to $414; forty-four defendants were discharged, and sentence was suspended in 111 cases. An interesting feature of the report is the low percentage of the accused who were fined from the Boroughs of Brooklyn, Queens and Richmond, as compared with those of Manhattan and Bronx.

NORTH CAROLINA

Personal.—Dr. William W. Faison, Goldsboro, has been elected for a second six-year term as superintendent of the State Hospital for Colored Insane. The institution now contains 730 patients.——Drs. Daniel G. Caldwell, Concord, and Gurley D. Moose, Mount Pleasant, have been elected members of Cabarrus County Board of Health.——The new Edgecombe County Board of Health has elected Drs. James C. Braswell, Whitakers, and Henry H. Whitaker, Hilliardston, as additional members of the board.——Drs. Andrew L. Pendleton and William J. Lumsden, Elizabeth City, have been appointed members of the board of health of Pasquotank County.

Hookworm Activity.—Dr. John A. Ferrell, assistant secretary of the State Board of Health, in his report of the hookworm investigation for the three months ended March 3, shows that 1,153 of the 1,500 practitioners in the state have made reports on hookworm disease, and 519 of these report that they have treated cases. All together 17,933 cases of hookworm were reported as having been treated by physicians of the state. Dr. Ferrell estimates that 25,000 cases have probably been under treatment. There were 16,994 specimens sent to the laboratory for examination and hookworm infection was found in 5,178 of these. The laboratory of hygiene has been made use of by 483 physicians up to date. In the inspection of schools, it is reported that 266 white and 69 colored schools have been inspected and that nearly 6,000 people have been informed about hookworm disease by public lectures. The number of school children reached by talks and visits of district directors of sanitation is estimated at 20,000. The state legislature made an appropriation of $5,000 for the work against hookworm.

OHIO

Laboratory Ready.—The bacteriologic laboratory of the Toledo health office, for which $1,000 was appropriated by the council, is now ready for operation.

Personal.—Dr. and Mrs. William B. Van Note have returned to their home in Lima after spending the winter in Miami, Fla.——Dr. John P. Beneke, Cincinnati, was painfully injured in a runaway accident, March 29.——Dr. Andrew J. Timberman, Columbus, who has been ill with septicemia in Lakeside Hospital, Cleveland, is reported to be improving.

TENNESSEE

Annual Clinic at Meharry.—The annual surgical clinic at Meharry Medical College, Nashville, was held March 13-18, with Dr. Daniel H. Williams, Chicago, as chief of clinic.

Does Not Want Prescriptions Refilled.—Washington County Medical Association, at a recent meeting in Johnson City, adopted a resolution demanding that prescriptions shall not be refilled by uruggists.

Folder on Tuberculosis—The board of health of Nashville has prepared an instructive folder on "Tuberculosis, Its Care and Prevention," which is being distributed very generally by the Antituberculosis League of Nashville.

State Association Meeting.—The seventy-eighth annual meeting of the Tennessee State Medical Association was held in Nashville, April 11-13, under the presidency of Dr. John A. Witherspoon, Nashville. Chattanooga was selected as the place of meeting for 1912. The following officers were elected: president, Dr. Charles J. Broyles, Johnson City; vice-presidents, East Tennessee, Dr. James H. Atlee, Chattanooga; West Tennessee, Dr. John D. Brewer, Newbern, and Middle Tennessee. Dr. Wesley J. Breeding, Ravenscroft; secretary-editor, Dr. Perry Bromberg, Nashville; delegate to the American Medical Association, Dr. Jere L. Crook, Jackson; alternates, Drs. Octavius Dulaney, Dyersburg, and A. Bennett Cooke, Nashville, to fill the unexpired term of Dr. Sidney S. Crockett, Nashville.

TEXAS

Gift to College.—Dr. and Mrs. James H. Wayland, Plainview, announce a gift of $100.000, on April 13, to the Wayland Baptist College, which bears their name.

Approves of Lay Press.—The question of whether the reports of meetings of Harris County Medical Society should be excluded from lay newspapers in the future was put to a vote at the meeting of March 31 and overwhelmingly voted down.

Man Arrested Was Not Member.—At the meeting of the Bexar County Medical Society in San Antonio, March 9, a resolution is said to have been adopted stating that "Dr. Herman T. Wolff, recently arrested by order of the justice of the peace, is not a member of this society and is in no way related to, and should not be confused with Dr. William M. Wolf, who is a worthy member in good standing of said county society."

Personal.—Dr. Joseph H. Reuss, Dallas, has purchased Salome Hospital, Cuero, from the Ladies' Hospital Association and will take charge of the institution about June 1.——Dr. John S. Turner, Dallas, has been reelected medical adviser of the Southland Life Insurance Company.——Dr. J. W. Sandlin has been appointed health officer of Humble.——Dr. Francis G. Floeckinger, Taylor, has let the contract for a private sanitarium to cost $15,000.

Medical Department Organized.—By orders from the adjutant general's office, March 27, the Medical Department of the Texas National Guard is defined. It consists of a medical corps with one chief medical officer with the rank of major, four majors, ten captains and seven first lieutenants. Dr. Alois B. Kennedy, Bonham, remains as chief medical officer. The hospital corps will remain as at present with headquarters in Dallas, and with Captain Fred B. Johnston, Dallas, in active charge.

UTAH

Ask for Military Sanitarium Near Salt Lake.—A memorial to congress asking that a naval and military sanitarium be established at the hot springs north of Salt Lake, and tendering a site free of cost to the government, has been adopted by both branches of the legislature.

District Society Election.—At the annual meeting of the First District Medical Society, held in Logan, the following officers were elected: president, Dr. David C. Budge, Logan; vice-president, Dr. Charles A. Canfield, Preston, Ida.; and secretary-treasurer, Dr. Eugene H. Smith, Ogden. The society passed a resolution that the State Board of Health be given power to require listing of social disease by number, the name of the individual affected not being given.

Elections.—At the annual meeting of the State Board of Health, Dr. Francis S. Bascom, Salt Lake City, was unanimously reelected president, and Dr. Theodore B. Beatty, Salt Lake City, secretary.——The Utah State Board of Medical Examiners met for reorganization, April 5, and elected Dr. David C. Budge, Logan, president; Dr. Frederick W. Taylor, Provo, vice-president; Dr. George F. Harding, Salt Lake City, secretary, and Dr. Frederick E. Straup, Bingham Canyon, treasurer.

Personal.—Dr. Albert N. Hanson, Salt Lake City, has been elected physician of Salt Lake County, vice Dr. Thomas G. Odell, Salt Lake City.——Drs. Philemon M. Kelly, American Fork, Horace C. Holbrook, Lehi, and Frank E. Winter, Payson, have been appointed deputy physicians of Utah County.——Drs. E. L. Emrich, Alexander G. Robertson, Sandy, Frederick E. Straup, Bingham, and Milford B. Bransford have been appointed health officers of the several districts of Salt Lake County.——Dr. T. William Stevenson has been appointed assistant physician of Salt Lake County.

GENERAL NEWS

Interurban Clinicians Meet.—The thirteenth meeting of the Interurban Clinical Association was held at Johns Hopkins Hospital, Baltimore, April 7 and 8. The meeting was opened by the president, Dr. Alfred Stengel, Philadelphia, and the address of welcome was made by Dr. Thomas McCrae of the medical staff of Johns Hopkins University.

Pathologists Elect New Officers.—The American Association of Pathologists and Bacteriologists held its annual meeting in Chicago, April 14, and elected the following officers: president, Dr. Richard M. Pearce, Philadelphia; vice-president, Dr. John J. McKenzie, Toronto, Ont.; secretary, Dr. Harold C. Ernst, Boston; and treasurer, Dr. Frank B. Mallory, Boston.

Congress on Hygiene.—The Fifteenth International Congress on Hygiene and Demography will be held at Washington, D. C., Sept. 23-28, 1912, authorized by Congress. Acceptances have already been received from twenty-two foreign governments. English, French and German are to be the official languages for papers and discussions. Dr. Henry P. Walcott, Boston, will be active president. Invitations have been sent to the governors of each state to appoint a committee of not more than five members to cooperate with the committee on organization in planning and preparing the exhibition of the congress. The secretary-general of the organization is Dr. John S. Fulton, Washington, D. C. Dr. William H. Welch, Baltimore, is chairman of the executive committee. The work of the congress will be divided in nine sections: that of hygienic microbiology and parasitology will be presided over by Dr. Theobald Smith, Boston; that on dietetic hygiene and hygienic physiology, by Prof. Russell H. Chittenden, New Haven, Conn.; that on hygiene of infancy and childhood and school hygiene, by Dr. Abraham Jacobi, New York City; that of industrial and occupational hygiene, by Dr. George M. Kober, Washington, D. C.; that of control of infectious diseases, by Dr. Hermann M. Biggs, New York City; that of state and municipal hygiene, by Dr. Frank F. Wesbrook, Minneapolis; that of the hygiene of traffic and transportation, by Dr. Walter Wyman, surgeon-general, U. S. P. H. and M.-H. Service, Washington, D. C.; that of tropical, military and naval hygiene, by Dr. Henry G. Beyer, medical director, U. S. Navy, Washington, D. C.; and that of demography by Prof. Walter F. Willcox, Cornell University, Ithaca, N. Y. The exhibition is intended to illustrate the present status and recent progress of public hygiene and vital statistics, especially in the United States, and will be kept open for a week or more after the close of the congress. The director is Dr. Joseph W. Schereschewsky, U. S. P. H. and M.-H. Service.

LONDON LETTER

(From Our Regular Correspondent)

London, April 8, 1911.

The Bleaching of Flour

As shown by the agitation in favor of "standard bread," described in a previous letter to The Journal, much attention is now being directed to the composition of bread, and the whiteness of bread, previously regarded as a sign of quality, is now denounced as obtained by sacrificing some of the most important constituents (protein and salts). The whiteness is sometimes obtained by chemical bleaching of flour and this is pointed out as another disadvantage, and Dr. E. W. Hamill, government food inspector, has issued an important report on this subject. The practice of flour bleaching originated in Great Britain about ten years ago. Various substances have been used as bleaching agents, but nitrogen peroxid is the only one which has given satisfactory results, and all commercial bleaching of flour at present depends on the use of this substance. Dr. Hamill thinks that when bleaching is properly carried out it produces no appreciable effect on the qualities of flour. It may be of assistance in maintaining uniformity in the appearance of flour milled from different wheats, but at the same time it enables the miller to use cheaper wheats and to transform what would otherwise be cheap dark-colored flour into a whiter higher-priced article. Owing to bleaching, color is no longer a criterion of the quality of flour. Among "improvers" added to flour is acid calcium phosphate. As this sometimes contains arsenic as an impurity this practice is serious. A sample improver recently examined was found to contain 0.07 grain of arsenic per pound. Dr. Hamill concludes that these sophistications are attended with risk to the consumer.

Prof. Karl Pearson's Work

In a previous letter to The Journal, the munificent endowment of a chair of eugenics at the University of London by the late Sir Francis Galton, and his wish that its first occupant should be Prof. Karl Pearson, were reported. The position of Professor Pearson in biologic science is rendered unique by his mathematical methods. As professor of applied mathematics in the University of London, he has brought to bear on biologic problems an unprecedented knowledge of mathematics. It was the work of Sir Francis Galton, who largely used mathematical methods, which induced Pearson to enter this field, in which he may now be regarded in some sense as Sir Francis Galton's successor. His first labors were directed to the discovery of methods for the description of the various types of variation in living creatures. These methods, which he elaborated more than fifteen years ago, have stood a prolonged trial. They have been used for the elucidation of an enormous mass of phenomena, ranging from the stature of school children to the powers of the leukocytes to ingest microbes. Sir Francis Galton first realized the importance of what is called correlation and showed how to measure it. Thus two characters are often found associated with a frequency which is greater than can be attributed to chance but not sufficient for the relation to be regarded as cause and effect.

there is a general impression that tall parents tend to have tall children; but it is also known that a tall father will not inevitably have a tall son. The relation between the stature of the parent and the stature of the son is neither one of obvious cause and effect on the one hand, nor one of pure chance on the other. To determine the exact value of the relation between these two extremes is the study of correlation. In this field. Prof. Pearson has worked indefatigably. He has devised methods for determining the correlation in a great variety of cases, and also for judging as to the weight to be attached to determinations based on a limited number of trials. In a long series of papers many of which have appeared in the the journal *Biometrika* edited by him, Professor Pearson and his pupils have applied these methods to problems taken from all departments of biology, medicine and sociology. The intensity of inheritance of physical and mental characteristics in man, variation in different types of plants and animals, the value of vaccination and antityphoid inoculation, the relation between social status and fertility, and the respective importance of hereditary tendencies on the one hand and of increased opportunities for infection on the other in the spread of consumption, are examples of the subjects discussed. The work has been done at the University of London Eugenics Laboratory established by Sir Francis Galton. Probably half of the rising generation of mathematical statisticians are pupils of Professor Pearson or have been profoundly influenced by his teaching.

Infectious Diseases in London

The epidemic of measles described in a previous letter to THE JOURNAL is on the decline. The deaths from the disease which in the preceding three weeks have been 175, 197 and 182 have fallen to 153 in the last week, but this figure is ninety-two above the average. The outbreak of small-pox is not yet quite over. Three patients have been admitted into hospital in the past week against ten, one and one in the previous three weeks. There are now twenty-eight small-pox patients in the hospitals.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, April 7, 1911.

Mild and Curable Forms of Myocarditis

On April 4, Dr. Charles Fiessinger of Paris read a paper before the Académie de médecine, the purpose of which was to show that toward the end of attacks of certain infectious diseases (acute articular rheumatism, influenza) asystolic conditions are observed which are really akin to mild forms of myocarditis. In spite of their gravity, these conditions of cardiac insufficiency may be completely cured under treatment by digitaline in small doses, continued over a long period, such as 0.0001 decimilligram of digitaline crystalisée for ten consecutive days. At the end of this period of time the medication is suspended for five days, then resumed during ten days, and so on for several months.

Salvarsan and Venous Thrombosis

On March 31, Dr. Darier, physician of the hospitals of Paris, read, before the Société médicale des hôpitaux, a paper by himself and M. Cottenot, on a series of observations which showed that thrombosis, which is sometimes observed after venous injection of salvarsan, is due to the hyperalkalinity of the solution, and that alkaline solutions of this drug are injurious to the red blood-corpuscles. One should, therefore, inject into the veins only a faintly alkaline solution prepared at the moment of using and containing an excess of sodium hydroxid only sufficient to prevent the solution from becoming turbid during its injection.

Dr. de Massary reported that he had made three intravenous injections of salvarsan in a woman. Two were made with a faintly alkaline solution; there was no alteration in the veins. The third was made wit ha hyperalkaline solution, and immediately during the injection the veins became indurated and remained so for fifteen days.

According to Dr. Milian, the formation of venous thrombosis is due, not only to the alkalinity of the solution, but also to the degree of dilution. Since he has used very diluted solutions followed by lavage of the wall of the vein with injected physiologic serum, he has not observed a single case of thrombosis.

The Name of Malta Fever

The discussion previously mentioned in THE JOURNAL (THE JOURNAL, March 11, 1911, p. 755), and the objections raised to a geographic name have caused the commission of the Académie de médecine to decide that it would be desirable to adopt a name founded on the pathogenesis of the disease. It has consequently adopted the term *mélitococcie*, which implies the idea of infection by a specific microbe common to man and to the lower animals, and which is, at all events, not offensive to any nationality.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, March 31, 1911.

Personal

On the ninetieth birthday of the prince regent of Bavaria, Prof. v. Müller of Munich received the title of privy court counselor.

Privat-docent Dr. Scheibe of Munich has been called to the chair of otology at Erlangen as the successor of Professor Denker.

Professor Winterstein has been appointed successor to Professor Nagel as director of the physiologic institute at Rostock.

Substitution of Roman Characters for German Script

The committee on petitions of the Reichstag has referred to the imperial chancellor a communication asking for official permission to substitute the Roman characters for the German script and gothic letters. The petition sets forth that it would be desirable for Germany to take this step which other nations took long ago. The angular so-called German script is not to be entirely suppressed, but the gothic characters are to be limited to ornamental printing, and it shall be taught in the third or fourth school year, so that pupils may be able to read it, but not be taught to write it. Against this proposition a great storm is rising, in which patriotism expresses itself in the preference for the German script. The argument is raised that for national reasons, the script used in Germany for hundreds of years should not be rejected. If, however, it is asserted that the angular letters are especially adapted to the words of the German language and that for this reason the public should not be deprived of them, it is sufficient to reply that in medical literature for decades the Roman characters have been employed almost exclusively for printing without a single physician making any objection to them.

The Third International Congress of Laryngology and Rhinology

While many congresses will meet this year in Dresden on account of the international exposition of hygiene, the third international congress of laryngology and rhinology will hold its meeting in the latter part of August in Berlin. At its head is the senior of the laryngologists, Prof. B. Fraenkel. I suppose that Professor Fraenkel retains his position only for the reason that he wishes to preside over the congress as an active professor; otherwise he would already have determined on account of his health to resign his office. Already 600 specialists from all civilized countries have announced their intention to be present at the congress. Representatives of the imperial and state authorities belong to the honorary committee. The municipal authorities of Berlin have appropriated $2,000 (8,000 marks) for the social features of the meeting.

A Motherhood Fund

In the small manufacturing city of Sebnitz in the so-called Switzerland of Saxony there has lately been created a local association to assist mothers. The occasion of this was the fact that in spite of the introduction of nursing premiums, only 55 per cent. of the women nursed their children and the infant mortality amounted to 20 per cent. All women living in the city may apply to the association if their own income or that of their family does not exceed $475 (1,900 marks) yearly. Membership once obtained does not expire until the income amounts to more than $600 (2,500 marks). The members pay a monthly fee of 12 cents (50 pfennigs) and receive in return the following assistance after childbirth: If the membership has continued for a year the fund pays back the monthly fees, $1.50 (6 marks), and adds $3.50 (14 marks) as lying-in money; two years' membership entitles one to $3.00 return fees and $4.50 lying-in money; three years' membership affords $4.50 and $5.50; that is, a lying-in woman who has belonged to the club three years receives from it $10 (40 marks). On the birth of twins an addition of $2.50 (10 marks) is paid. If the child dies during the first week or is born dead, only the fees are returned. If the mother dies, the child or the father of a legitimate child may claim the complete amount. Needy nursing mothers who belong to the club are entitled, in addition to the lying-in money, to a liter of milk daily for the improvement of their own nutrition.

Miscellany

A Bill to Establish a Department of Health, and for Other Purposes

Senator Owen, on April 6, introduced Senate Bill 1, to take the place of S. B. 6049, introduced by him at the last session of Congress. The bill follows:

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled:

Sec. 1. That there be at the seat of government an executive department known as the Department of Health, and a Director of Health, who shall be the head thereof; and the provisions of title four of the Revised Statutes, including all amendments thereto, are hereby made applicable to said department. The Director of Health shall be appointed by the President, by and with the advice and consent of the Senate, at a salary of $——— *per annum* and with tenure of office like that of the heads of the other executive departments. And said director shall cause a seal to be made for the Department of Health, of such device as the President approves, and judicial notice shall be taken of said seal.

Sec. 2. That there be in the Department of Health an assistant to the Director of Health, designated and known as the Commissioner of Health, who shall be a skilled sanitarian, appointed by the President, by and with the advice and consent of the Senate, who shall serve at the pleasure of the President, and who shall receive a salary of $——— *per annum*. The Commissioner of Health shall perform such duties as are required by law and such as are prescribed by the Director of Health. There shall be also a chief clerk, a disbursing clerk, and such other employees as Congress may from time to time authorize. The auditor for the state and other departments shall receive and examine all accounts of moneys paid in and of moneys expended on account of the Department of Health, and shall certify the balance arising thereon to the Division of Bookkeeping and Warrants of the Treasury Department, and forthwith send a copy of each such certificate to the Director of Health.

Sec. 3. That it be the province and duty of the Department of Health to foster and promote all matters pertaining to the conservation and improvement of the public health and to collect and disseminate information relating thereto: *Provided*, That this act shall not be construed as attempting to authorize the Department of Health to exercise or attempt to exercise, without express invitation from the chief executive or other proper authority of the state, any function belonging exclusively to such state, or to enter any premises in any state without the consent of the owner or occupant thereof; but the Director of Health, on request of the chief executive or other proper authority of any state, territory, the District of Columbia or any insular possession, may detail for limited periods an officer or officers, employee or employees, from the Department of Health to assist the health authorities of such state, territory, district or insular possession in protecting and promoting the health of the people of such jurisdiction: *And provided further*, That the Department of Health shall recognize no so-called school or system of medicine.

Sec. 4. That to the Department of Health are hereby transferred the following bureaus, divisions and other branches of the government, and all that pertains to them, and they and each of them shall remain under the supervision and direction of the Director of Health until otherwise directed by law, namely:

(a) From the Department of the Treasury is transferred the Public Health and Marine-Hospital Service.

(b) From the Department of Agriculture is transferred that part of the Bureau of Chemistry charged with the investigation of the adulteration of foods, drugs and liquors, and with the execution and enforcement of the act of Congress entitled "An act for preventing the manufacture, sale or transportation of adulterated or misbranded or poisonous or deleterious foods, drugs, medicines and liquors, and for regulating traffic therein, and for other purposes," approved June 30, 1906.

(c) From the Department of Commerce and Labor is transferred the Division of Vital Statistics, Bureau of the Census.

And the President is hereby authorized to transfer to the Department of Health at any time, either the whole or any part, as to him may seem best, of any bureau, division, or other branch of the government engaged in work pertaining to the public health, except the Medical Department of the Army and the Bureau of Medicine and Surgery of the Navy.

And each and every function, authority, power, duty and jurisdiction, of whatsoever character it may be, vested at the time of any transfer aforesaid in the head of the executive department from which such bureau, division or other branch of the government is transferred, shall, to the extent to which such function, authority, power, duty or jurisdiction pertains to such bureau, division or other branch of the government, immediately on such transfer become vested and thereafter remain vested in the Director of Health.

All land, buildings, furniture, apparatus, equipment and property of whatsoever description, and all official records and papers, in the custody of any executive department from which any bureau, division or other branch of the government is transferred as aforesaid and pertaining to the business of such transferred bureau, division or other branch of the government, shall at the time of such transfer, or as soon thereafter as practicable, and in so far as such action can be taken without hindering the work of the executive department from which such transfer is made, be given over into the custody of the Department of Health. And all unexpended balances of appropriations available at the time of such transfer for the use of any such transferred bureau, division or other branch of the government, or which may become available thereafter, shall be and remain available, in similar manner and to the same extent as if no transfer had been made.

Sec. 5. That within the Department of Health there shall be the following bureaus: (a) Bureau of Sanitary Research; (b) Bureau of Child Hygiene; (c) Bureau of Vital Statistics and Publications; (d) Bureau of Foods and Drugs; (e) Bureau of Quarantine; (f) Bureau of Sanitary Engineering; (g) Bureau of Government Hospitals; (h) Bureau of Personnel and Accounts. And the Director of Health is hereby authorized to arrange and rearrange from time to time, with the approval of the President, the functions, duties, personnel, papers, records and property, and the work, resources, and equipment generally, coming into the jurisdiction and control of the Department of Health by the operation of this act, so as most efficiently and economically to organize and maintain the several bureaus herein named and such divisions and offices thereof as to said director seems proper; but in arranging and rearranging the personnel, the rank, pay and allowances of the officers of the Public Health and Marine-Hospital Service commissioned at the time of the transfer of that service to the Department of Health shall not, by reason of anything in this act contained, be diminished. And the Director of Health may call on the heads of other executive departments for information in their possession whenever such information is needed for the efficient and economical working of the Department of Health.

Sec. 6. That the President is hereby authorized to detail officers and employees from any of the several executive departments of the government for duty under the Director of Health when so requested by said director, and to detail officers and employees in the service of the Department of Health to any of the other executive departments on request of the head of such department, provided such detail can be made without prejudice to the public service, to carry into effect the purpose and intent of this act; but officers and employees so detailed shall receive no additional compensation, but shall be paid such actual and necessary expenses as they incur in the discharge of their duties.

Sec. 7. That the Director of Health may, in his discretion and with the approval of the President, appoint an advisory board of not more than seven members, to confer with him on his request, from time to time as he deems necessary, concerning the work of the Department of Health and the health of the people. The members of said board shall be selected because of their special knowledge of matters relating to the public health, and each shall hold office for a term of seven years or until his successor is appointed, except that the appointments first made, and appointments thereafter made to fill unexpired terms and terms of members who have held over beyond the periods of their original appointments, shall be made so that not more than one member shall retire during any one fiscal year. No member of any such advisory board shall receive any compensation for his services, but each shall be paid all actual expenses necessarily incurred in the discharge of his duties. And from and after the passage of this act the advisory board for the Hygienic Laboratory created by section five of an act entitled "An act to increase the efficiency and change the name of the United States Marine-Hospital Service," approved July 1, 1902, be, and the same hereby is, abolished.

Sec. 8. That the Director of Health may, whenever in his judgment public interests would be promoted by so doing, invite the duly constituted health authorities of all or of any of the states, territories, the District of Columbia and insular possessions as to him may seem advisable, each to send one delegate to confer with him or his duly appointed representative or representatives and with each other, at such time and place as he may designate, concerning any particular matter or matters relating to the public health; and it shall be the duty of the Director of Health, on the written application of the duly constituted health authorities of not less than five states, territories, the District of Columbia or insular possessions, stating the particular matter or matters which it is desired to consider, to appoint a time and place, and to call a conference of the health authorities of the states, territories, the District of Columbia and insular possessions that united in the request therefor, and personally or through his duly appointed representative or representatives to be present at such conference; but every state, territory, the District of Columbia and insular possession shall be notified of every conference, and if practicable be afforded an opportunity of being present and participating in its proceedings. And from and after the passage of this act annual and other conferences of state and territorial boards of health, quarantine authorities and state health officers, provided for by section seven of an act entitled "An act to increase the efficiency and change the name of the United States Public Health and Marine-Hospital Service," approved July 1, 1902, be, and the same are hereby, abolished.

Sec. 9. That, except as expressly provided in this act, nothing herein contained shall be construed as limiting or abrogating any function, right or duty imposed by law on any existing bureau, division or other branch of the government; but such bureaus, divisions and other branches of the government as are by this act or by authority thereof transferred to the Department of Health shall continue, under direction of the Director of Health, to have such functions, duties and rights as they have at the time of such transfer; and in the case of such bureaus, divisions and other agencies of the government as are transferred in part only, the part not transferred shall continue to have and to exercise all such functions, duties and rights, except such as specifically relate to the part transferred to the Department of Health, in the same manner and to the same extent as if no such transfer had been made.

Sec. 10. That the Director of Health shall annually submit to Congress a report in writing showing the operations of the Department of Health during the last preceding fiscal year, which report shall give an account of all moneys received and all moneys disbursed on account of such operations. He shall make such other reports from time to time as may be required by the President, or by either House of Congress, and such as are in his judgment necessary or expedient.

Sec. 11. That $——— be, and the same are hereby, appropriated to carry into effect the provisions of this act, out of any money in the Treasury not otherwise appropriated.

Sec. 12. That all acts and parts of acts contrary to the provisions of this act or inconsistent therewith be, and the same are hereby, repealed.

Sec. 13. That this act shall take effect on and after July 1, 1912.

Cystic Disease of the Breast with Carcinoma.—It is difficult to estimate the exact etiologic relation that the presence of a cyst bears to the formation of a carcinoma, but the association of the one with the other is sufficiently common to justify the routine removal of such cysts.—H. M. Rigby, in the *Practitioner*.

Deaths

Leartus Connor, M.D., one of the distinguished ophthalmologists of the middle west, a leader in medical education, and in the uplift of the medical profession, died at his home in Detroit, April 16, from cerebral hemorrhage, aged 68.

Dr. Connor was a native of Coldenham, N.Y., took his academic course at Williams College, and his medical course at the College of Physicians and Surgeons, New York City, from which he graduated in 1870. In 1871, he located in Detroit and at once began his work as a medical teacher as lecturer on chemistry in Detroit Medical College. From 1872 to 1879, he was professor of physiology and clinical medicine; from 1878 to 1881, professor of didactic and clinical ophthalmology and otology, and from 1875 to 1881, secretary of the college. In 1871, Dr. Connor became editor of the *Detroit Review of Medicine and Pharmacy* and continued as its editor through its various changes of name to the *Detroit Medical Journal*, *Detroit Lancet*, and *American Lancet*, his editorial work continuing until 1895.

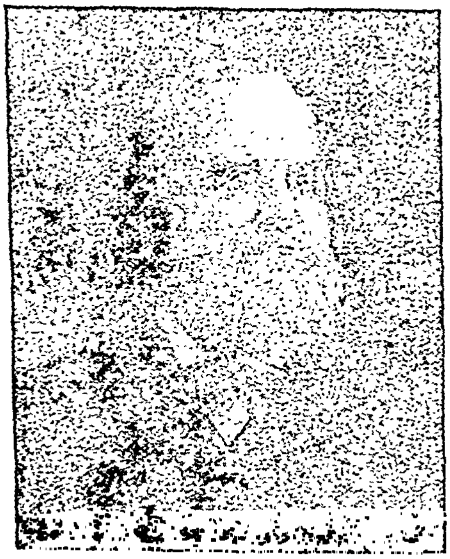
He was an active and prominent member of the American Medical Association for many years, was second vice-president in 1882, a member of the original board of trustees appointed in the same year, a trustee in 1887-8, and again in 1892-3, and chairman of the Section on Ophthalmology in 1891. He was president of the Michigan State Medical Society in 1901-2, and chairman of its council from 1902 to 1905; president of the Detroit Academy of Medicine, 1877-8 and 1888-9, and its secretary 1871-2; secretary of the American Medical College Association; and president of the American Academy of Medicine and of the American Medical Editors' Association, 1883-4.

He was attending physician for several years to St. Mary's Hospital, ophthalmic and aural surgeon to Harper Hospital since 1881, and to the Detroit Children's Free Hospital since 1887, and was consulting ophthalmologist to the Woman's Hospital, from 1881 to 1890.

A testimonial dinner was given to Dr. Connor by his colleagues in Detroit, February 25, in honor of the completion of his fortieth year in practice.

Wayne County Medical Society at its regular meeting April 17, adopted resolutions of eulogy and sympathy, and adjourned without taking up the program for the evening. Funeral services were held April 18.

In addition to his editorial work, Dr. Connor made many valuable contributions to the literature of ophthalmology. He was largely responsible for the activity displayed by various associations in the regulation of the teaching of ophthalmology in the colleges so that every practitioner would have the ability to refract correctly and render the service to his patients which the optometrist is trying to render. Dr. Connor was a loyal friend, and an enemy who always fought fairly; no one ever questioned his good faith. His precept and example were an inspiration to his younger confrères, and his death will be lamented, not only by them, but by his many friends throughout the United States.



LEARTUS CONNOR, 1843-1911

Charles Augustus Oliver, an ophthalmologist of international repute, died at his home in Philadelphia, April 8, from uremia, aged 57. He was a native of Cincinnati, but went to Philadelphia when a child, pursued his medical studies at the University of Pennsylvania and was graduated from the medical department of that institution in 1876. He was a member of the American Medical Association, American Association for the Advancement of Science, American Philosophical Society, and American Ophthalmological Society, and was an active, honorary or corresponding member of many other medical and scientific societies in this country and abroad. He was attending surgeon to the Wills Eye Hospital, ophthalmologist to the Presbyterian Hospital, and consulting ophthalmologist to the Friends' Hospital for the Insane and the State Hospital for the Chronic Insane. He was a prolific writer on his specialty, co-author with Dr. Norris of the "Textbook of Ophthalmology," and author of several books and monographs on ophthalmology. He was a fellow of the Philadelphia College of Physicians and founder of the Wills Eye Hospital Ophthalmic Society. He was made associate clinical professor of ophthalmology in the Woman's Medical College of Pennsylvania, Philadelphia, in 1897, and later on was made clinical professor in that institution. Dr. Oliver had suffered from nephritis about three years.

Albert Rufus Baker, M.D. Western Reserve University, Cleveland, 1879; a member of the American Medical Association, and chairman of the Section on Ophthalmology in 1893-4; professor of ophthalmology, otology and laryngology since 1888 in the Cleveland College of Physicians and Surgeons, and chairman of the faculty from 1898 to 1902; oculist and aurist to St. Alexis and Cleveland General Hospitals; expert on the local board of U. S. Pension Examining Surgeons; president of the Association of American Medical Colleges in 1900-01 and of the Cuyahoga County Medical Society; a fellow of the American Academy of Medicine; editor of the *Cleveland Medical Gazette* from 1885 to 1896; died at his home in Cleveland, April 5, aged 53.

John H. Janeway, M.D. University of Pennsylvania, Philadelphia, 1852; Colonel Medical Corps, U. S. Army, retired, died in the Kenilworth, (Ill.) Sanitarium, April 14, from paralysis, aged 82. Dr. Janeway entered the Medical Corps of the Army in 1861, and served throughout the Civil War, being brevetted major and lieutenant colonel for gallantry. He was retired with the rank of lieutenant colonel on account of age, August 12, 1893, and afterward made his home with his son in Chicago and Kenilworth. He had been disabled for several years on account of cerebral hemorrhage.

Thomas B. Hart, M.D. College of Physicians and Surgeons, Chicago, 1894; a member of the American Medical Association; formerly a practitioner of Mount Etna, Ind.; medical superintendent of the New Mexico Miners' Hospital; president of the New Mexico Medical Association; vice-president of the New Mexico Board of Health; health officer of Colfax County; city physician of Raton, assistant local surgeon of the Santa Fe System; and president of the local board of pension examiners; died at his home in Raton, April 5, aged 46.

Chester West Stranahan, M.D. University of Buffalo, N. Y., 1863; Jefferson Medical College, 1867; formerly a member of the American Medical Association; a member of the Medical Society of the State of Pennsylvania; surgeon in charge of St. Vincent's Hospital, Warren, from 1892 to 1902; local surgeon of the Lake Shore and Michigan Southern Railway Company; died at his home in Erie, April 6, from paralysis, following a cerebral hemorrhage four years before; aged 65.

Byron Frank Porter, M.D. Medical School of Maine, Brunswick, 1850; a member of the Maine Medical Association; in 1885 and 1886, a member of the Maine legislature; for fifteen years supervisor of schools, and for many years United States pension examiner; said to have been the oldest practitioner in the state; died at his home in Newport, April 6, from senile debility, aged 82.

Noah M. Glatfelter, M.D. University of Pennsylvania, Philadelphia, 1864; for three years a surgeon of volunteers during the Civil War; well known as a horticulturist and botanist and a recognized authority on willow culture and the culture of mushrooms; died at his home in St. Louis, April 2, from the results of injuries received in a fall two days before, aged 73.

Charles Hadley Spinning (license, Washington, 1881); a graduate of the Eclectic Medical Institute, Cincinnati, in the late forties; twice a member of the Washington state legislature, and once state senator; for nine years physician to the Puyallup Indian Agency; for many years a practitioner of Tacoma; died at his old home in Prosser, April 1, aged 90.

Theodore A. Wagner, M.D. Indiana Medical College, Indianapolis, 1876; a member of the Indiana State Medical Association; a member of the consulting staff of the Indianapolis City

Hospital; once coroner of Marion County, and chairman of the mayor's advisory committee; died in St. Vincent's Hospital, Indianapolis, April 9, from cerebral hemorrhage, aged 62.

Alexander Arthur McLarty, M.D. Detroit College of Medicine, 1893; of Manistee; a member of the Michigan State Medical Society; supreme examiner of the Modern Romans; acting assistant surgeon U. S. P. H. and M.-H. Service; died at St. Mary's Hospital, Rochester, Minn., March 27, after an operation for carcinoma of the stomach, aged 43.

Frank D. Putnam, M.D. Bellevue Hospital Medical College, 1875; a member of the American Medical Association; formerly president of the Cayuga County Medical Society; city physician of Auburn, N. Y.; died in the Auburn City Hospital, April 5, two days after an operation for the removal of gallstones, aged 59.

Richard W. Ivers, M.D. Baltimore (Md.) Medical College, 1895; a member of the Connecticut State Medical Society; for several years a member of the staff of the Emergency Hospital, Bridgeport, Conn.; for three years chief surgeon of the Barnum and Bailey circus; died at his home in Middletown, Conn., April 2, aged 40.

John Ligon, M.D. University of Virginia, Charlottesville, 1868; surgeon of the Nineteenth Virginia Cavalry, C. S. A., during the Civil War; for many years a member and president of the Pocahontas County (W. Va.) Court; died at his home in Clover Lick, April 3, from cerebral hemorrhage, aged 77.

Ethan P. Allen, M.D. Rush Medical College, 1866; a veteran of the Civil War; for more than twenty years a practitioner of Stillman Valley, Ill., but later of Rockford; physician of Winnebago County; died at the Ransom Sanitarium in that city, April 6, from cerebral hemorrhage, aged 70.

George A. Doss, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1901; president of the state eclectic association in 1908; professor of specific medication and diagnosis in the Hospital Medical College (Eclectic) Atlanta; died in a sanitarium in that city, April 2, aged 34.

Henry Clay Perry, M.D. Rush Medical College, 1857; acting assistant surgeon in the Army during the Civil War; and thereafter a resident of Ord, Neb.; several times mayor, and for many years supervisor of the city; died in San Diego, Cal., February 2, from heart disease, aged 77.

Caroline M. Stengel, M.D. Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1893; of Santa Clara, N. Y.; a member of the Woman's Medical Association of New York City; died in Hoboken, N. J., Oct. 23, 1910, from tuberculosis.

Henry E. Cassel, M.D. University of Minnesota, Minneapolis, 1884; a member of the American Medical Association; director and chief surgeon of the Litchfield (Minn.) Hospital; died in Luther Hospital, St. Paul, April 4, from septicemia, due to an operation wound, aged 51.

Alexander Werth, M.D. University of Berlin, Germany, 1860; a veteran of the Civil War; and afterward United States pension examiner in St. Louis; died at his home in that city, April 7, from septicemia, following an amputation of the leg above the knee, aged 70.

Albertus Adair Moore, M.D. New York University, New York City, 1859; a member of the South Carolina Medical Association; and formerly a member of the State Board of Health; died at his home in Camden, Nov. 26, 1910, from arteriosclerosis, aged 76.

William C. Mason, M.D. Howard University, Washington, D. C., 1884; formerly of Indianapolis; for thirty years a medical examiner of the Pension Office, Washington, D. C.; a veteran of the Civil War; died at his home in Washington, March 28, aged 65.

William Henry DeCourcy, M.D. New York, 183—; of Cheston-on-the-Wye, Queen Anne's County, Md.; who gave up practice after a short time to look after his estate in Maryland; died at Johns Hopkins Hospital, Baltimore, April 5, from senile debility, aged 87.

John David Carnahan, M.D. University of Virginia, Charlottesville, 1872; a member of the Medical Society of Virginia; a pioneer practitioner of Ogden, Utah; and a Confederate veteran; died at his home in Ogden, April 2, from septicemia, aged 63.

Robert A. Walker, M.D. College of Physicians and Surgeons, Baltimore, 1882; a member of the Medical Society of the State of Pennsylvania; of Rockville; died at the home of his sister in Wilkinsburg, March 29, from cancer of the intestines, aged 54.

Charles Foster Gardner, M.D. Syracuse (N. Y.) University, 1898; of Westhampton Beach; a member of the Medical Society of the State of New York; died in Roosevelt Hospital, Manhattan, March 31, after an operation, from septicemia, aged 38.

John F. Hutchins, M.D. Texas Medical College, Galveston, 1868; Tulane University, New Orleans, 1868; a member of the American Medical Association, and a Confederate veteran; died at his home in Oakland, Tex., Dec. 5, 1910, aged 69.

Richard Kuehne, Jr., M.D. Long Island College Hospital, Brooklyn, N. Y., 1904; of West Hoboken; a member of the Medical Society of New Jersey; died in Nassau, Bahama Islands, June 16, 1910, from chronic nephritis, aged 27.

George S. Luck, M.D. Washington University, Baltimore, 1873; a Confederate veteran, and a member of the Roanoke (Va.) Academy of Medicine; died at his home in that city, March 19, from cerebral hemorrhage, aged 64.

Herman T. Wolff, M.D. University of Halle, Germany, 1878; of San Antonio, Tex.; died in Baylor Hospital in that city, April 1, from the effect of morphin, self-administered, it is believed with suicidal intent, aged 59.

Russell J. Dimon, M.D. Albany (N. Y.) Medical College, 1883; formerly a member of the Medical Society of the State of New York; of Hastings; died at the Hospital of the Good Shepard, Syracuse, March 28, aged 58.

Isaac Franklin Noel, M.D. American Medical College, Eclectic, St. Louis, 1881; a member of the Missouri State Medical Association; died suddenly in his office in Unionville, April 4, from cerebral hemorrhage, aged 53.

Mahlon Kohler Mathus, M.D. Missouri Medical College, St. Louis, 1855; a resident of Sangamon County Ill., for sixty-five years; died at his home in Williamsville, March 22, from cerebral hemorrhage, aged 86.

Agnes Christy Patterson, M.D. Boston University School of Medicine, 1900; of Malden, Mass.; died in the Massachusetts Homeopathic Hospital, Boston, March 20, after an operation for gastric ulcer, aged 48.

Ranny Phelps Malay, M.D. University of Alabama, Mobile, 1884; a member of the South Dakota State Medical Association; died at his home in Aberdeen, April 4, from pneumonia, aged 51.

Emile Laurent Marie Tilley, M.D. University of Tennessee, Nashville, 1886; of Kaplan, La.; died in St. Mary's Hospital, Patterson, La., Dec. 21, 1910, from carcinoma of the stomach, aged 49.

Jacob Rohrer Johns, M.D. Jefferson Medical College, 1889; for many years a practitioner of Chadd's Ford, Pa.; died at his home in Philadelphia, April 6, from locomotor ataxia, aged 49.

Jared E. Brooke, M.D. Indiana Central Medical College, Greencastle, 1851; a surgeon of volunteers during the Civil War; died at his home in Plymouth, Ind., March 31, aged 91.

James M. Brittain, M.D. Missouri Medical College, St. Louis, 1873; a Confederate veteran; and a pioneer citizen of Jacksonville, Tex.; died at his home in that place, April 2, aged 80.

Louis A. McCord, M.D. St. Louis College of Physicians and Surgeons, 1892; of Cristoval, Tex.; was shot and killed in San Angelo, Tex., in a feud fight, March 31, aged 45.

Simon M. Brainin, M.D. University of Dorpat, Russia, 1881; a member of the Medical Society of the State of New York; died at his home in New York City, March 31, from chronic nephritis, aged 56.

John Washington Steel, M.D. Eclectic Medical Institute, Cincinnati, 1857; died at his home in Shelbyville, Tenn., February 7, from cirrhosis of the liver, aged 80.

Albert Badger, M.D. New Orleans, 184—; for nearly seventy years a practitioner of Missouri; died at his home in Schell City, March 14, from senile debility, aged 89.

Lafayette Washington Herrington, M.D. Kentucky School of Medicine, Louisville, 1893; died at his home in Rawson, O., Dec. 29, 1910, from pneumonia, aged 75.

Warren W. Bowles (license, Kansas, 1901); for thirty-five years a practitioner of Bunker Hill; was killed in a runaway accident near Luray, April 5, aged 71.

James Cress, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1862; died at his home in North Georgetown, O., April 2, from pneumonia, aged 80.

Joseph Smillie, M.D. University of Toronto, Ont., 1901; died at his home in Binbrooke, Ont., July 30, 1910, from cystic tumor of the cerebellum, aged 37.

Aubry Linton Mahon, M.D. College of Physicians and Surgeons, Memphis, Tenn., 1909; died at his home in Gould, Ark., March 30, from nephritis, aged 26.

Charles Oliver Sumner, M.D. Kansas City (Mo.) Medical College, 1885; died at his home in Alma, Colo., January 19, from pleuropneumonia, aged 53.

Hiram W. Harding, M.D. University of Maryland, Baltimore, 1860; a Confederate veteran; died at his home at Wicomico Church, Va., March 24, aged 73.

Claude Fowler Hickman, M.D. Chattanooga (Tenn.) Medical College, 1908; died at his home in Bristol, Va., April 7, from tuberculosis, aged 26.

Marriages

BEN PARMENTER, M.D., to Miss Ethel Brumfield, both of Bellmont, Ill., April 1.

WILLIAM K. CHATTLE, M.D., to Miss Eva Mae Haus, both of St. Louis, March 4.

CARL WILLIAM WAHRER, M.D., to Miss Julia McConn, both of Fort Madison, Ia., April 8.

FRANK R. SPENCER, M.D., Boulder, Colo., to Miss Edith Clayton of Kankakee, Ill., April 5.

STANLEY E. KERRICK, M.D., to Miss Winifred Thompson, both of Minneapolis, April 18.

SCOTT DUDLEY BRECKINRIDGE, M.D., to Miss Gertrude Ashby Bayne of Washington, D. C., April 19.

PHILIP F. HEROD, M.D., Alva, Okla., to Miss Ruby Kelley of Kansas City, Mo., at El Reno, Okla., March 31.

WILLIAM G. PRUYN, M.D., Mexico City, Mex., to Miss Bessie Rea of San Francisco, at Mexico City, March 30.

Conservative Surgery of Trees.—Trees, like human beings, may have their lives and usefulness extended by intelligent medical treatment or by conservative surgery; indeed, the analogy, when one comes to think about it, is striking. In addition to conditions which must be treated surgically, they are subject to various diseases, due mostly to insect parasites. When these parasites attack leaves or bark, the trees may be said to be treated medically, as in the use of sprays for the eradication of scale or other insects. Trees are also affected by under-nourishment and are subject to traumatisms and decay. In their capacity of furnishing wholesome foods, in their chemical activity in utilizing carbonic acid gas and giving off oxygen, in affording protection from the heat of the sun, as well as by appealing to our esthetic sense, trees have a distinct influence on the health and happiness of the people. They are therefore worthy of care. In treating pathologic conditions in trees many principles apply that are applicable to treatment of human beings. In the case of infesting parasites, parasiticides and disinfectants are used. In the conditions requiring surgery, which constitute perhaps the larger proportion of tree ills, almost the same surgical principles apply. A broken limb may be put in splints, a limb torn or broken off may be bandaged with protective material to exclude decay. Transplantation of twigs or branches may be done, as in grafting or budding, and more formidable injuries or large areas of decay may be healed by still more radical surgery. The tree surgeon must understand thoroughly tree anatomy and tree nature, and must take into consideration the mechanical effect of winds, etc. When large areas of decay are present in limb or trunk, this decay must be thoroughly eradicated, just as the dentist or the surgeon cleans out carious teeth or bone; a species of asepsis or antisepsis must be observed to kill off the factors causing decay, and then the cavities must be filled with some material impervious to moisture and which will support a possibly greatly weakened trunk or limb. As a filling material, cement, along with its other numerous uses, has been found to be one of the best. A tree thus carefully treated, either medically or surgically, responds marvelously, and its life may be saved and its existence greatly extended. Considerable cavities thus filled with cement often heal and are even covered over with bark, leaving only a scar, just as surface wounds in animal life are covered with protecting epithelium.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

EIGHTEENTH CENTURY MATERIA MEDICA

The changes that have taken place in medical thought and practice within the last two hundred years are nowhere more evident than in that branch of medicine dealing with therapeutic agents—materia medica. It is both interesting and instructive to compare the present status of certain drugs which we now recognize as some of the most useful in the physician's armamentarium, with the standing of the same medicaments two hundred years ago.

Herman Boerhaave, a Dutch physician, born in 1668, stood, in his day, in the vanguard of the medical profession. In 1709, he became professor of medicine and botany at the University of Leyden, having previously held the position of lecturer on the theory of medicine in the same institution. It is said that Boerhaave's reputation was so high that, at one time, he received a letter from a Chinese mandarin addressed: "To Boerhaave, Physician in Europe."

It may be fairly admitted that Boerhaave's statements on the drugs in use in his day are representative of his time. For this reason the following quotations take on an added interest. In 1775 a small book was published by one Richard Goade, a London druggist, entitled "Boerhaave's Materia Medica, or the Druggist's Guide, and the Physician and Apothecary's Table-Book." Goade says, in his preface, that his book is but "a Translation of a Latin Manuscript which was given to me by Dr. James Carroll, taken from the Mouth of the great Professor Boerhaave, in a Course of Lectures."

The few quotations which are here given have been selected chiefly because of the comparative importance of the drugs and partly because of the change that has taken place in the medical profession's estimate of their medicinal value. Except that the modern form of the letter "s" has been substituted for that which appears in Goade's work, the composition and spelling have been closely followed:

ARGENTUM. *Silver.* A Metal well known in common Use, but little in Medicine. It is found pure and native in the Earth in some Places; in others mixed with the Ores of Lead, and other mineral Substances; beaten into Leaves, it is used to cover Boluses. The Preparations from it are the Chrystals made by setting a strong Solution of it to chrystalize; and the Lunar Caustic made from an evaporated Solution of the same Metal, or from the melted Chrystals. Both are Caustics but they are little used.

A Solution of Silver in Aqua Fortis, stains Agate: The Figures made by Art in those Stones are done by covering the Surface with Wax, cutting the intended Figure through the Wax, and pouring on the Solution, which penetrates into the Stone.

ARGENTUM VIVUM. *Quicksilver.* A fluid Semi-Metal, found sometimes native and pure, oftener in Form of Cinnabar or other Ores. Factitious Cinnabar is an artificial Mixture of Sulphur and Quicksilver; Native Cinnabar is a natural Mixture of the same Ingredients. We have it from Spain, Hungary, and the East, and also the Quicksilver Native or obtained from it.

Taken in its crude or native State is excellent against Obstructions, an Ounce or two for a Dose: Large Quantities are sometimes given in obstinate Obstructions of the Bowels, but it is a desperate Practice. Externally mixed into Ointments it cures the Itch, and other cutaneous Foulnesses; and will raise Salivation.

The Preparations of it kept in the Shops, are numerous and of great Virtue. Factitious Cinnabar, made by subliming Quicksilver and Sulphur. Æthiops Mineral, by grinding Quicksilver and Sulphur together. Corrosive Sublimate, made by subliming Quicksilver Nitre, Vitriol, and Sea-salt. Mercurius Dulcis or Calomel, made by subliming several Times Crude Mercury and Corrosive Sublimate. Calcined Mercury, made by keeping

Quicksilver *over a small Fire till* it becomes a reddish Powder. White Precipitate, made by dissolving Corrosive Sublimate and Sal Ammoniac in Water, and precipitating with Oil of Tartar. What is called Red Precipitate, made by evaporating a Solution of Quicksilver in Aqua Fortis: And Turpeth Minerale, made by evaporating a Solution of Quicksilver in Oil of Vitriol, and pouring on Water. All these are powerful Medicines, but they must be *given* with Caution.

Crude Quicksilver for internal Use should be reduced from Cinnabar; and Sophistications are so common, every one ought to do it for himself.

ARSENICUM. *Arsenick.* A Chemical Preparation made in Germany, and kept by our Druggists. It is properly the Flowers of Cobalt, a poisonous Mineral found in many Parts of *Europe*, and affording also the fine blue Substance called Smalt. The Cobalt is burnt in a reverberatory Furnace, and the Flowers or Soot collected from its long Chimney, make Arsenic. From the Remainder of the Cobalt, Smalt is made, by adding Sand and Pot-ash, and running all into a Kind of Glass of a deep Blue.

The Soot of the Cobalt sublimed alone, makes the common White Arsenick; Yellow Arsenick is made by adding Sulphur to the Soot before Sublimation, and the Red by adding Sulphur and the Scoriae of Copper.

They are all Poisons, and of no Use whatsoever in Medicine: The Deaths that have been occasioned by them, should incur a severe Penalty on whosoever sold or kept them.

DIGITALIS. *Fox-Glove.* A wild Herb brought entire to the Markets. It is a Yard high, and has large red Flowers.

The fresh Leaves given in Infusion, are a rough Vomit, but it is not used except by the Country People.

An Ointment made of the Flowers boiled in Lard, has been supposed to have great Virtues against Piles: but it is not in much Esteem at present, except amongst the good Women.

GENTIANÆ RADIX. *Gentian Root.* A Long, thick Root of a yellowish brown Colour, with little Smell, but very bitter to the Taste. We have it from Germany, where they dry some in the open Air and some in Ovens. The latter Kind is worst, 'tis too dry, brittle, and often burnt. The Plant which produces it is common in our Gardens, and has large broad Leaves and little blue Flowers.

It is an excellent Stomachick, with Orange Peel and a little Galangal *it makes an* excellent bitter Infusion in Wine or Water.

IPECACUANHA. *Indian Root.* Two Kinds of Ipecacuanha are imported, a brown and a grey; but as the grey is the Kind that ought to be used, 'tis Pity the other is brought over. Both are from the Spanish West-Indies. The grey or right Ipecacuanha is long slender, twisted and annulated; greyish on the Surface, and paler within; the Brown is smaller; it is of a deep brown on the Surface, and white within. The grey has not much Smell, this has less; the Taste of both is disagree*able.* The Plant to which we owe the one, affords also the other: the only Difference is, that the brown is starved, the grey grows in a rich Soil. The Plant is ten Inches high, and has a few Leaves at the Top only, the Flowers are white, and are succeeded by Berries.

The Root is the best Emetick we *know, and* is *almost* the only Medicine used at this Time for that purpose. It has also a great Astringency, and taken for a Length of Time in small Doses, cures Dysenteries.

NUX VOMICA. *The Vomic Nut.* A rounded flat Fruit of the Breadth of a Shilling, striated, tough and of a whitish Colour, and of an horribly acrid bitterish Taste. We have it from the East-Indies. The Tree which produces it is large and beautiful. Its Fruit is of the Bigness, Shape and Colour of an Orange, and in each there are about fifteen Kernels, which are these Nuces Vomicæ.

They are used as a Poison for Animals. They have been *recommended* however, in small Doses internally as a Medicine, but we have seen ill Consequences attend them, and we have so many safe Medicines for the same Purposes, that it is rash to use them.

SABINA. *Savin.* The young Branches with the Leaves of the Garden Shrub of this Name, brought fresh to Market. The Leaves are little, of a bright Green, and terminates in *Prickles.*

It is *famous* for a Promoter of the Menses and it will cause Abortion; but great Danger as well as Guilt attends the Use of it to such Purposes: Many have *perished* by it.

SARSAPARILLÆ RADIX. *Sarsaparilla Root.* A Root brought over in long slender Pieces, which are usually split, and have the inner Part taken out, before they are sold for Use. When entire, the Root consists of a Head of the Bigness of a Walnut, from whence these Strings or Fibres grow in great Numbers, and to a great Length, but the Fibres only are used. They are of a greyish Colour on the Outside, and white within, of no Smell, and but little Taste. We have it from South America. The Plant is one of the prickly Bindweeds.

It is esteemed a great Sweetener of the Blood, a Sudorifick and Attenuant. It was once pretended to be a remedy for the Pox.

SENA. *Sena.* The Leaves of a small Shrub, but so carelessly collected, that we find Fragments of the Stalks and the Seed-Vessels among them. They are oblong, sharp-pointed, of a pale Green, fleshy, of little Smell, but of a Mawkish, unpleasant Taste. This is the Alexandrian Sena, the only Kind that should be kept. There are two other Kinds, one from Tripoly, with greener and blunter Leaves; another from Mocha, the Leaves of which are long and narrow. They have all the same Virtues, but the Alexandrian is greatly to be preferred. The Leaves are alated, and the Flowers are like Pea-Blossoms, but yellow streaked with purple.

Sena is an excellent gentle Purge: There have been many Ways invented to disguise its Taste, but none is so well as the old Womens Method of stewing it with Prunes, which also assist it in its Operation.

TOLUTANUM BALSAMUM. *Balsam of Tolu.* A Resin of the Consistence of thick Honey, of a brownish Colour, of a very fragrant Smell, and of an acrid Aromatick Taste. We have it from New Spain, in Shells of Gourds. It is thin when first put up, but thickens in keeping. The Tree which affords it, is a small Pine, frequent in South America.

It is an excellent Balsam in Consumption; for it is less acrid than any of the others; It has also their Virtues of a Detergent and Diuretick.

State Laws Against Drug Adulteration

The federal authorities, since the passage of the National Food and Drugs Act, have done much to improve the quality of drugs on the market. This law, however, being a federal one, applies only to goods shipped from *one* state to another, an *spurious or adulterated drugs may* be *manufactured* in a stat and shipped to, and exposed for sale in, all parts of the state and yet be entirely without the province of the federa authorities. Such adulteration is entirely a matter for th state authorities to correct. Unfortunately, the individual states as a rule, have not had efficient laws or the laws have been a dead letter. Conditions are changing, however, and such states as North Dakota, Massachusetts, Pennsylvania, New York and a few others are giving evidence that efforts are being made to check the traffic in adulterated drugs. We have before us a circular which indicates that Kentucky is one of the states that not only has a law for the regulation of the sale of medicines but is seriously concerned with its enforcement. The circular shows that Kentucky is concerned not only with the prosecution of offenders against the law but also takes the broader view and proposes also to combat the evil by educational methods. Thus it says:

> Two years' work under the Kentucky Food and Drugs Act has convinced those engaged in the enforcement of the drug sections of that act that there are two classes of adulterations: first, adulterations due to willful intent or gross carelessness; second, adulterations due to various trade and professional problems, which this office believes can be better overcome through mutual assistance rather than prosecution.

For the seminar the following comprehensive *program* is proposed:

> (*a*) The general application *of the state* and federal pure-food laws for the drug business. (*b*) The drug regulations and notices of judgment under the federal law. (*c*) The regulations under the state law. (*d*) *The proper* labeling of patent and *proprietary* medicines under the law. (*e*) The proper labeling of U. S. P. and National Formulary products under the law. (*f*) Necessary equipment for a druggist's laboratory. (*g*) Drug store *management* and equipment. (*h*) Problems connected with the preparation, storage and handling of various pharmaceutical preparations. (*i*) *Standard* weights and measures. (*j*) The soda fountain. (*k*) Other similar subjects.

It is to be hoped that the pharmacists of Kentucky will avail themselves of the opportunity thus offered.

Correspondence

A Case of Near Blackmail

To the Editor:—It is seldom that the publisher of one of the popular magazines comes as near placing himself in the position of being accused of blackmail, as did the publisher of *Good Housekeeping* in its February number. Beneath the heading of the article, "Why Our Glasses Don't Fit," appears a statement which at once leads the reader to suspect that the editor had some misgivings as to the advisability of publishing the article. He must have succeeded in getting the "endorsement of two distinguished oculists" for he says so; and obtaining the distinguished endorsements, he proceeds to publish the article which consists of an assumed case of eye-strain, and the trials and tribulations of a patient—the author—and of an oculist, who with the patience of a Job, as the history relates, makes twenty odd separate and distinct examinations and prescribings of faulty lenses, at which juncture the oculist discovers his trial lenses, and incidentally nearly all other trial lenses in this country and Canada, to be faulty; and all because neither he, nor his brother oculists, as well as various opticians, manufacturing and otherwise, are testing out their trial cases and prescribed lenses by a certain apparatus which "costs sixty dollars"—"possessed by not over fifty opticians and oculists out of 28,000 in the country!" And hereby hangs a tale.

The manufacturer must needs make some sales. The apparatus is not selling well, at least the author makes that inference very strong in the article. Probably he needs the money, and hence this advice to the public: "You can make your oculist a better one by asking him some questions which will worry him. 'Have you yourself tested your trial lenses?' 'Have you a modern axis finder to enable you to test them? And to test also the centering of these lenses I have bought from the optician? Are you sure the man you are sending me to has a machine? If he hasn't why don't you make him get one?'" And now, the manufacturer having had the benefit of this most excellent advertisement, published in the body of a popular magazine, in the form of a most readable and interesting article—and it is interesting—follows up the advertisement by sending out broadcast over the country reprints of the same. "From *Good Housekeeping* Magazine by Permission" accompanied by a picture of the apparatus, and a letter stating among other things, that this is "The Instrument to which Prof. Tassin"—the author of the article—"alludes."

W. H. Dudley, Los Angeles, Cal.

STING OF THE PORTUGUESE MAN-OF-WAR

To the Editor:—Please give me any information you can in regard to the treatment of stings by the Portuguese man-of-war fish. I have had a number of cases on this coast, but have not been able to give much relief. R. S. Lowry, Fort Lauderdale, Fla.

Answer.—Apparently a confusion has arisen between the Portuguese man-of-war fish (*Nomeus gronorii*) and the Portuguese man-of-war (*Physalia pelagica, Physalis pellagica, Holothuria physalis*).

The Portuguese man-of-war fish is closely related to the sergeant fishes. It is of small size and inhabits tropical parts of the Atlantic and Indian oceans. Our species lives commonly under the protection of the Portuguese man-of-war, swimming freely among its poisonous tentacles.

The Portuguese man-of-war is one of the so-called jelly-fish belonging to the *Siphonophora.* It floats on the surface of the water and has long retractile tentacles, sometimes several feet in length, and containing batteries of stinging capsules, powerful enough to sting the hand as severely as a nettle. The greater the number of the cells which sting an individual, the more severe is the pain. A poison has been isolated from *Physalia* by Portier and Richet (1902) under the name of "hypnotoxin." Solutions of this substance killed experimental animals; they became somnolent and death followed through paralysis of the respiration. The intensity of the effects are supposed to depend also on the size of the animal. After removal from water, the stinging property diminishes, but it is reported that the irritative property, unattended, however, by any of the constitutional effects, remains in the tentacles for a long time. Bennett (1831) even reports that in touching a handkerchief some weeks after it had been used in wiping off some of the portions of the tentacles the stinging property was found to have remained, although it had lost its virulent quality, which produced on fresh application violent constitutional symptoms.

Portuguese man-of-war stings are so rarely observed by the average American physician that the following personal experimental experience published by Bennett will doubtless be of interest: "On taking hold of the animal, it raised its tentaculæ and stung me on the second and ring fingers. The sensation was similar at first to that produced by the nettle; but before a few minutes had elapsed, a violent aching pain succeeded, affecting more severely the joints of the fingers, the stinging sensation at the same time continuing at the part first touched. On cold water being applied, with the intention of removing or lessening the pain, it was found rather to increase than to diminish the painful effects. The irritation resulting from the poisonous fluid emitted by the animal extended upward, increasing in extent and severity (apparently acting along the course of the nerves), and in the space of a quarter of an hour the pain in the forearm (which was more particularly referable to the inner part) was very violent, and at the elbow-joint it was still more so. It may be worthy of remark that when the joints became affected the pain always increased. The pain became at last almost unbearable, and was much increased on the affected arm being moved; the pulse of that arm was also much accelerated, and an unnatural heat was felt over its whole surface. The pain extended to the shoulder-joint; and on the pectoral muscle becoming attacked by the same painful sensation, an oppression of breathing was occasioned, which we find produced in a similar manner by rheumatism, when it attacks that muscle; and it proved very distressing during the time it remained. The continuance of the pain was very severe for nearly half an hour, after which it gradually abated, but the after-effects were felt during the remainder of the day in a slight degree of numbness and increased temperature of the arm. . . . About two hours after I had been stung, I perceived that a vesicle had arisen on the spot; and when children have been stung, I have observed that numerous small vesicles arose, similar to those produced by the nettle."

Dr. Clarke Abel describes his own symptoms, mentioning especially "the aching pain in the armpit, accompanied by a sense of restriction within my chest; within fifteen minutes all uneasiness ceased."

It has been very difficult to trace much recent literature of more than very general statements on this subject, and in the articles consulted there is considerable contradiction.

According to popular belief, the sting of *Physalia* may be very dangerous, even resulting in death of a person or of animals, and if certain animals eat *Physalia* their flesh is alleged to become poisonous. These views find both acceptance and denial in medical and scientific writings, and it is difficult to escape the thought that the entire subject of *Siphonophora* stings might well be restudied with profit. Some points of confusion existing in the literature may possibly be traceable to the fact that doubts exist as to the correct zoologic determination of the animal which has produced serious results in certain cases. That the stings of some jelly-fish are insignificant and wear off promptly, so that no medical treatment is necessary, may be readily admitted, but that "no remedy except patience" is called for we are scarcely prepared to admit for those instances in which very severe pain and various other symptoms develop.

Just what treatment would be best we are unprepared to say, for the subject has not been sufficiently studied, and with the exception of Old's (1908) paper, little of a satisfactory nature exists in literature bearing particularly on this phase of the subject. That morphin can be used to relieve the pain is evident, and on general grounds one would be inclined to suggest local alkaline applications as used by Old, provided the case was seen immediately.

One of the most important papers on jelly-fish stings was recently published by Assistant Surgeon E. H. H. Old, U. S. Navy. It is based on nine cases (one fatal) recently observed in the Philippines. The symptoms appeared in from ten minutes to an hour. In four cases there were marked hysterical symptoms, with incessant cough, restlessness, pain and nausea, while in four cases the marked hysterical condition was not present. In treatment, Old used alkaline solution locally and morphin sulphate hypodermatically. The following may be quoted as an example of the cases Old observed:

"V., a hospital attendant at Canacao, on June 21, 1907, while in bathing off the hospital wharf, was stung by a jelly-fish. He said that he was some distance from the landing and as soon as he felt the sting he turned back to the wharf. On his way he felt some pain across his back, but thought it was due to swimming. On his way up from the wharf to the hospital he began to feel badly and sat down for a little while. When he reached the hospital, about thirty minutes after he had been stung, he became prostrated and had to be carried to a bed.

"On arrival I found a slightly raised, vesiculated, red area over the left biceps muscle. This 'wept' like an eczema. The patient was throwing himself around the bed and coughing almost incessantly, expectorating a thin mucus. He complained of nausea but did not vomit. His face was congested and anxious. He wept at intervals, a stream of tears flowing down his face. The nose was occluded as in a bad case of coryza and from it a thin mucus was discharging. He complained of pain in his head and of marked pain in the lumbar region. He expressed much anxiety as to his condition and exclaimed now and then: 'I don't know why, but I've lost all my nerve.' His temperature was 38 C. (100.2 F.); pulse 100, strong and full. The examination of urine and blood showed nothing abnormal.

"Morphin sulphate 1/6 grain was given by hypodermic injection, an alkaline solution was applied to the arm. The symptoms subsided shortly after and in a few hours the temperature was normal and the pulse 60. The next morning the patient felt weak and complained of a slight sore throat; the pharynx was slightly inflamed."

In the foregoing we have used many words in failing to give a direct answer to our correspondent's question, but if this lengthy confession of relative ignorance will lead to a careful study of the subject our time (about three entire days of one man) used in looking into the literature (both medical and zoologic) in the hope of finding something satisfactory, will have been well spent. Possibly some of our readers are more fortunate than we have been and can give more definite information than we have been able to trace.

In conclusion it may be mentioned that divers, subc as sponge-fishers, are subject to an affection due to contact with celenterates. Smearing the body with fat is said to be a satisfactory preventive measure against this trouble.

WHAT KIND OF INFECTION?—PROBABLY ANTHRAX

To the Editor:—W. H., aged 17, male, coal miner and farmer, squeezed a blackhead and it developed into a small pimple surmounted by a crust. The patient scratched this crust off with his finger-nail. In less than twenty-four hours the lip and cheek began to swell, and in thirty-six hours the swelling was unusually large. At this stage I found him with a temperature of 102 F., pulse 98, very little pain, in fact, more discomfort than pain; he was unable to be up. There was no redness, no pustule.

I thought of erysipelas, actinomycosis, poison ivy. There were no horses nor cattle he could think of having been near, nor was there any poison ivy. I applied a lotion of saturated solution of boracic acid and alcohol, and gave a cathartic and a few powders. In twelve hours more the swelling became much worse; in fact, terrific; there was no heat or pronounced redness; nor was there sharp outlined margin. A small black spot developed at the corner of the mouth; the lips were swollen and parched. Both eyes were closed and a secretion was on the eyelashes like that seen in small children. All the swelling had a blue-black discoloration. Temperature was 103 F., pulse 110. There was neither crepitation nor fluctuation.

A few incisions were made, but they afforded no relief. They were painless. A small quantity of dark and thin fluid escaped, no gas, no odor, no pus. Some incisions were deep, some rather superficial. I also gave 10 c.c. antistreptococcus serum, and covered the swollen area with the solution already mentioned.

All the symptoms and swelling increased; the small black spot spread over the mucous membrane of the cheek and developed into necrosis. The patient died four and a half days after onset of symptoms. In the last twenty-four hours the disease resembled puerperal fever, the temperature being up to 107 F.; there was feeble, almost imperceptible, pulse. During his illness the man received 30 c.c. of antistreptococcus serum.

What kind of an infection was this? Septicemia appears on the death certificate. August Bechtold, M.D., New Athens, Ill.

Answer.—The pimple surmounted by crust which was removed with the finger, the great swelling, the watery fluid which exuded from the incisions, the absence of pain, the bluish discoloration, the development of gangrene, the high temperature and the very rapid progress ending in death point clinically to infection with the anthrax bacillus. This could easily have been verified by a microscopic examination of the fluid from the open pimple.

TINCTURE OF WHITE SOAP

To the Editor:—Some time ago you published a formula for making a neutral liquid soap. I have lost this recipe. Please publish it again. E. J. Bernstein, M.D., Kalamazoo, Mich.

Answer.—Our correspondent probably refers to tincture of white soap, the formula of which was given by F. P. Dunnington, Charlottesville, Va., in the *Old Dominion Journal of Medicine and Surgery*, August, 1909, and which was quoted in the Department of Current Medical Literature of The Journal, Sept. 25, 1909, p. 1058, as follows (with apothecaries' amounts added):

℞		gm. or c.c. for 1 gallon.
White castile soap (Conti's)	℥xl	1,200
Ammonia water, stronger	fl.℥iii	100
Alcohol	Oii	1,400
Water, distilled	q. s. ad. Oviii	4,000

The specific gravity of this mixture is 0.97, which is identical with that of green soap. Soft water (rain-water) might well be substituted for the distilled water in the formula.

To make one gallon: Mix the liquids for it in a one-gallon jar and then add the soap, previously cut into coarse shavings. Crowd all the soap into the jar and cover it with a glass plate. After twelve hours stir, and again stir after some hours. Allow to settle twelve hours, and then filter, decant or syphon off the clear liquid into a can, which may be kept closed. There will remain a few ounces retaining the impurities of the soap, which may be used for less particular washing. If this liquid is exposed to evaporation for a few hours, ammonia and alcohol escape, and a mass of the consistency of green soap will be obtained. While this preparation is said to be free from the objections to tincture of green soap, it presents the additional advantage of costing but $1.50 a gallon, and, if the alcohol is obtained tax-free, the cost will be about 60 cents a gallon, while tincture of green soap will cost $1 or more.

DIFFERENCE BETWEEN A VEGETABLE AND AN ANIMAL CELL

To the Editor:—What is the difference between a vegetable cell and an animal cell? I can find nothing on this subject in any of the books I possess; from what I know of the subject I can see no difference. A. D. Bundy, Osage, Iowa.

Answer.—The fundamental difference appears to be physiologic and connected with the separate manner of nutrition prevailing in the two kingdoms. The typical vegetable builds up its structure from carbon dioxid, water, ammonia and other substances existing in the air and soil. The animal has not this power and must use the material already formed by the vegetable or by other animals. As a result of this mode of nutrition it is found that cellulose, a modification of starch, is found only in vegetables and is employed by most vegetables in forming the cell wall. Cellulose is never found in the cell walls of animals. Some vegetables do not form cell walls composed of cellulose and such vegetable cells have no essential distinguishing features to differentiate them from animal cells.

The Public Service

Medical Department, U. S. Army

Changes for the week ended April 15, 1911.

Crampton, Louis W., colonel, relieved from duty in the Philippines division and will proceed on transport to sail from Manila, P. I., to San Francisco, about Sept. 15, 1911, and on arrival at the latter city to report by telegraph to the adjutant general of the Army for further orders.

McEnery, Douglas W.; Turnbull, Samuel J., and Upshur, Alfred P., M.R.C., ordered to active duty and will proceed to San Antonio, Texas, for duty with the maneuver division at that place.

Boehs, Charles J., M.R.C., ordered to active duty and will proceed to Plattsburg Barracks, N. J., for duty at that place.

Ragan, Charles A., captain, assigned to permanent duty at Walter Reed General Hospital, Takoma Park, D. C.

Kendall, William P., lieut.-colonel, left Fort Riley, Kan., on thirty days' leave of absence.

Wallace, George S., M.R.C., left Fort Sam Houston, Texas, for duty in the field at presidio of Texas.

McMillan, C. W., lieut., relieved from duty with the maneuver division, San Antonio, Texas, about July 1, 1911, and ordered to Fort St. Michael, Alaska, for duty.

Whaley, Arthur M., captain, on being relieved from duty at Fort St. Michael, Alaska, by First Lieutenant McMillan will proceed to Seattle, Wash., for further orders.

Roberson, Horace M., lieut., relieved from duty with the maneuver division, San Antonio, Texas, about July 1, 1911, and ordered to Fort Davis, Alaska, for duty.

Harmon, Daniel W., lieut., on being relieved from duty at Fort Davis, Alaska, by First-Lieutenant Roberson will proceed to Seattle, Wash., for further orders.

Gosman, George H. R., major, left Fort Barrancas, Fla., for Tokyo, Japan, for duty as attache at the American embassy.

DeLaney, M. A., major, ordered to proceed to Philadelphia on official business pertaining to the medical corps of the Army.

Medical Corps, U. S. Navy

Changes during the week ended April 15, 1911.

Ames, M. H., P. A. surgeon, detached from the naval hospital, Olongapo, P. I., and ordered to temporary duty on board the *Albany*.

Turner, H. W. B., asst. surgeon, detached from the *Barry* and the Asiatic torpedo fleet and ordered to the naval station, Olongapo, P. I.

Thomas, G. E., asst. surgeon, detached from the naval station, Olongapo, P. I., and ordered to temporary duty on board the *Saratoga.*

Hart, S. D., asst. surgeon, detached from the *Mohican* and ordered *to the Barry.*

Cook, F. C., surgeon, ordered to command the naval hospital, navy yard, Puget Sound, Wash.

Hale, G. D., P. A. surgeon, detached from the *Idaho* and ordered home to await orders.

Manchester, J. D., P. A. surgeon, detached from the naval recruiting station, Chicago, and ordered to duty at the naval hospital, naval training station, North Chicago.

Smith, W. B., P. A. surgeon, orders of March 17 modified; ordered to duty at the naval hospital, Annapolis, Md.

Ely, C. F., P. A. surgeon, detached from the naval hospital, Philadelphia, and ordered to the naval proving ground, Indian Head, Md.

Halton, E. P., asst. surgeon, detached from the naval medical school, Washington, D. C., and ordered to the naval station, Guam, M. I.

Brown, E. M., asst. surgeon, detached from the naval proving ground, Indian Head, Md., and directed to await orders.

Ohnesorg, K., surgeon, detached from the *Prairie* and ordered home to await orders.

Stuart, Jr., D. D. V., asst. surgeon, detached from the naval medical school, Washington, D. C., and ordered to the *Idaho.*

Mears, J. B., P. A. surgeon, detached from the *Franklin* and ordered to the Asiatic station.

Howard, J. V., asst. surgeon, detached from the naval medical school, Washington, D. C., and ordered to the *Supply.*

Pratt, L. L., Omelvena, J. G., and O'Malley, J. J., asst. surgeons, detached from the naval medical school, Washington, D. C., and ordered to the Asiatic station.

Crow, G. B., asst. surgeon, detached from the naval station, Guam, M. I., and ordered home to await orders.

Toulon, A. J., asst. surgeon, detached from the *Supply* and ordered home to await orders.

Elmore, B., A. A. surgeon, ordered to the marine recruiting office, district of the Pacific coast, Seattle, Wash.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended April 12, 1911.

Stimpson, W. G., surgeon, directed to proceed to Marcus Hook, Pa., and Delaware Breakwater quarantine station on special temporary duty.

Anderson, J. F., P. A. surgeon, detailed to represent the Service at the meeting of the American Association of Pathologists and Bacteriologists to be held in Chicago, April 14-15, 1911.

McClintic, T. B., P. A. surgeon, directed to proceed to Delaware Breakwater quarantine station on special temporary duty.

Vogel, C. W., P. A. surgeon, directed to proceed to Marcus Hook, Pa., on special temporary duty.

Warren, B. S., P. A. surgeon, granted fourteen days' leave of absence from April 8, 1911, on account of sickness.

McKeon, F. H., P. A. surgeon, relieved from duty at the immigration station, San Francisco, and directed to report to the commanding officer of the Revenue Cutter *Rush* for duty.

Bailey, C. A., A. A. surgeon, directed to accompany the staff of the U. S. Immigration Service from St. John, N. B., to Quebec, P. Q., for the inspection of arriving aliens.

Hough, J. S., A. A. surgeon, granted thirty days' leave of absence to be taken at such times as may be approved by Surgeon B. W. Brown.

McLarty, A. A., A. A. surgeon, died March 24, 1911.

Board of medical officers convened to meet at the Bureau, April 11, 1911, for the examination of Assistant Surgeon J. R. Hurley, and reconvened, April 24, 1911, for the examination of Assistant Surgeon W. M. Bryan, to determine their fitness for promotion to the grade of passed assistant surgeon. Detail for the board: Assistant Surgeon-General W. J. Pettus, chairman; Assistant Surgeon-General L. E. Cofer; Passed Assistant Surgeon L. L. Lumsden, recorder.

Board of medical officers convened to meet at San Francisco, April 24, 1911, for the examination of Assistant Surgeon A. J. Lanza, to determine his fitness for promotion to the grade of passed assistant surgeon. Detail for the board: *Surgeon Rupert Blue,* chairman; Passed Assistant Surgeon M. W. Glover; Passed Assistant Surgeon Friench Simpson, recorder.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

LEGAL RIGHTS AND OBLIGATIONS OF PHYSICIANS *

John E. Kehoe

CHICAGO

The most important legal question for the physician is that which relates to the rights, duties, legal obligations, responsibilities and liabilities of the physician in caring for his patient. This is becoming a more important question every day. Litigation in the nature of suits for damages of various kinds is, at present, occupying about three-quarters of the time and attention of the courts of Cook County. It almost seems as if the entire populace was trying to find an excuse for suing somebody for damages, and, in this epidemic of damage litigation, physicians and surgeons are by no means forgotten. If a person is dissatisfied with the professional service rendered by the physician or surgeon, it apparently is becoming almost the rule, rather than the exception, to consult a lawyer and see if some basis cannot be found for starting a suit for damages in which the lawyer, as a rule, agrees to accept a contingent fee, consisting of a percentage of the amount to be recovered. It becomes a very important matter, therefore, for the physician to know what his legal rights and obligations are, in order that while doing his full duty to his patient he may, at the same time, protect himself from the danger, embarrassment and annoyance of a claim for damages in case his patient is dissatisfied. A physician's rights and legal obligations are controlled by certain legal principles which, grouped together, are known as the law of negligence. Negligence is defined in law to be an omission to do something which a reasonable man, guided by those considerations which ordinarily regulate the course of human affairs, would do; or, doing something which a reasonable and prudent man would not do. In order to maintain an action for negligence, there must be shown to exist some obligation or duty which has been left undischarged or unfulfilled.

To understand just what constitutes legal actionable negligence on the part of a physician, it is necessary to bear in mind the various degrees of care which the law exacts under various conditions. There are a number of degrees of care under the law: First, there is the highest degree of care which human forethought, reason and diligence can attain. Where the law imposes this highest degree of care, as, for instance, in the case of a railroad company carrying passengers for hire, the slightest negligence or simplest omission of duty becomes actionable in law. This highest degree of care, however, is not exacted or required of a physician or surgeon under the law of this state, or in any other state of the Union. The next degree of care, under the law, is what is known as ordinary care or reasonable care, and is defined in law as being that degree of care which an ordinarily prudent person would exercise under the same circumstances or conditions. This is the degree of care which, together with the exercise of a proper degree of skill, is required in law from a physician or surgeon in the discharge of his duty to his patient.

Going on down the scale, there is a lack of care known to the law as gross negligence which, of course, both as a matter of reason and law, would lay the foundation for damages. There is also known to the law what is called wilful or wanton misconduct, which may be defined as an act showing a willingness to harm the person in question, or such an utter disregard of his rights as to indicate an abandoned or malignant heart. Such conduct in any walk of life would be actionable, and the law says that, as against a claim for wilfulness or wantonness, it is not even necessary that the person presenting the claim must show himself to have been in the exercise of ordinary care.

It will be seen from the above that neither is the highest degree of care exacted of, nor is a low degree of care tolerated on, the part of the physician or surgeon. In other words, the physician and surgeon is held in law to the exercise of ordinary, reasonable care and skill. In general, his duty may be defined substantially as follows: The physician is bound to bestow such reasonable ordinary care, skill and diligence as physicians, in the same neighborhood, in the same general line of practice, ordinarily have and exercise in like cases. Time and locality are to be taken into consideration, and the physician is bound to exercise the average degree of skill possessed by the profession in such locality. In the absence of special agreement, his engagement is to attend the case as long as it requires attention; unless he gives notice of his intention to discontinue his visits, or is dismissed, he is bound to exercise *reasonable and ordinary care* and skill in determining when his attendance should cease. But his engagement is not to cure the patient, that is, he does not insure that his treatment will be successful; the mere failure to effect a cure does not even raise a presumption of a want of proper care, skill or diligence. It is the duty of the patient to cooperate with the physician and to conform to his prescriptions and directions, and, if he neglects to do so, he cannot hold the physician responsible for his own neglect. On the other hand, he has a right to rely on the instructions and directions of his physician, and incurs no liability by so doing.

---

* Read before the Evanston Branch, Chicago Medical Society, March 30, 1911.

This is substantially the rule in Illinois and in practically every other state. There is an implied contract on the part of the physician that he possesses that reasonable degree of skill, learning and experience which is ordinarily possessed by others of his profession, and that he will use reasonable and ordinary care and diligence in the treatment of the case committed to him, and that he will use his best judgment in all cases of doubt, as to the best course of treatment. He is presumed to possess the degree of skill above defined, and to exercise reasonable care and to use his best judgment, but he does not guarantee that his judgment is infallible, and he cannot be held in law responsible for an error of judgment where he shows that he exercised ordinary care, and that he possessed the skill ordinarily possessed by others of his profession in the given locality. His failure to effect a cure can never be held to indicate even a presumption of want of care or skill. It will be noted that the locality is a matter to be taken into account. In a rural community with limited opportunities, the same degree of skill is not required as that which is exacted in a metropolis, where superior advantages are available. For instance, a general practitioner who had had but little experience in the treatment of the eye would not be justified in performing a delicate and dangerous operation on the eye of a patient in a community where a specialist of especial skill and experience is obtainable; while the same general practitioner might be entirely justified in law in attempting the same operation in a community where it was impossible to secure the services of such a specialist. Time and place, therefore, cut some figure in the matter, but the general rule remains universally true that only such care and skill are required as are possessed and applied by physicians in good standing in the community. The Supreme Court of this state has said that you cannot exact of the physician the highest degree of skill which the most learned might acquire in the profession, nor can you regard him as an insurer of the successful termination of his work; that he is not required to possess the highest order of qualifications to which some men attain, but that he must possess and exercise the degree of skill which ordinarily is possessed by members of his profession in good standing. For anything short of a reasonable amount of care and skill in his practice the law will hold him responsible, but the burden always rests on the one presenting the complaint to show that the physician was deficient in this regard. If the physician, in the exercise of reasonable care and skill, uses his best judgment in case of doubt, he cannot be held for a want of success, and so, in the treatment of disease or injury, he is bound to bring to his aid such obtainable remedies and appliances as discovery and experience have found to be most appropriate and beneficial in aiding recovery. But it may often happen that the most appropriate appliances or remedies are the very simplest and most commonplace, and, in such case, he is bound only to use his best judgment with reasonable care and skill. He is not liable, even if injurious results follow his treatment, unless it is shown that such injurious results were due to a failure to use ordinary reasonable care and skill. A fatal result may follow from the peculiar condition of a patient of which the physician had no knowledge, or the peculiar temperament of the patient over which he had no control, and, in such case, the exercise of his best judgment, with the care above defined, constitute a complete defense. The fact that a patient grew worse under the treatment of one physician and became better under the care of another, does not even raise a presumption in law that the treatment of the first was not proper. In other words, the law will not permit the drawing of a conclusion of unskilfulness from the result of the treatment alone. A physician, in passing from a patient infected with a contagious disease to others who are not so infected, must take such reasonable precautions as experience has shown to be necessary to prevent the communication of the infection, but if he does this he will not be held liable for the consequences. In the application of the general rule, a physician is chargeable with the knowledge of the probable consequences of the form of treatment or operation that he undertakes, and is expected to exercise ordinary care and skill to prevent unfavorable consequences. Under the general rule of wilfulness and wantonness, a physician may be held liable for exemplary damages, that is, damages by way of punishment, if it be shown that he was guilty of such a gross want of care as to indicate that he was probably conscious of the consequences of his carelessness and indifferent to the danger to which he subjected the patient.

The patient has a right to assume that one holding himself out as a surgeon possesses reasonable skill; and so, if a physician attempts to perform surgical operations, when his lack of experience renders it impossible for him to exercise ordinary skill, his ignorance of the knowledge of his profession will not constitute an excuse.

The principle of ordinary care applies also to the question of attendance on a patient; that is, there is a duty on the physician to continue his attentions so long as from the condition of the patient one might reasonably expect him, in the exercise of an honest judgment, to believe it necessary, and any culpable neglect on his part in this regard would render him liable to an action. A physician who leaves a patient at a critical stage of a disease, without reason or without attempting to procure another medical attendant, would be held in law to be guilty of actionable negligence. Of course, if he is discharged by some one in authority, this relieves him of responsibility; but ordinarily he must exercise reasonable care in determining when his attendance may be safely discontinued; but no error of judgment in this regard, or any other matter pertaining to his treatment will render him liable for consequences where he keeps within recognized and approved methods, and uses his best judgment with ordinary care and skill. No error of judgment will hold the physician responsible, unless it is so gross as, on its face, to imply a want of ordinary care and skill. Of course, an error of judgment may be so great as to be inconsistent with the belief that ordinary care and skill were exercised. For instance, a man might hold himself out to the world as an oculist, without any knowledge of the science, and obtain a patient and commence tinkering with the most delicate of all the organs, the eye, and destroy the sight. Perhaps it would only be an error of judgment, but it would be such an error as to constitute malpractice.

The physician must exercise ordinary care in giving proper instructions to those in attendance on the patient, and a failure in this regard, if it results in damage to the patient, is actionable. In other words, he must exercise the same care in giving proper instructions to the attendants, where attention is necessary in his absence, as he gives in his own work on the case.

Another principle to be borne in mind is that the physician must follow established practice. The rule is very strict against trying experiments. On its face, this rule seems rather harsh, because it means that any advancement in the profession must be at the personal risk of the physician rather than of the patient. It has been held in many of the states that any deviation from the established mode of practice is sufficient to charge the surgeon in the case with any injury resulting to the patient. In general, the physician is bound by what is universally settled in the profession, not by what some writers and practicing surgeons recommend. If the ordinary and established practice of the profession is to treat an ailment in a particular manner, and the attending physician adopts some other mode that proves injurious, it is immaterial how much skill he possessed, since his experiment failed. If the settled practice of the profession allows but one course of treatment in the case, any departure from such course is at the physician's risk. He cannot try experiments with his patient to the patient's injury.

When we consider the wonderful advance in medicine and surgery from generation to generation, and consider how near it comes to being an exact science to-day, and how crude and barbarous were the methods described by early writers, and when we remember that all of this advance is the result of new discoveries, new experiments and new methods developed by skilled and learned members of the profession from age to age, the rule above set out seems very harsh, but it is an almost universal rule and it is one that physicians must bear in mind for their own protection.

There are some modifications to the rule: In case of emergency, when there is no well-known method that could be relied on in the particular case, and when the physician must act hastily with such means as are at his command, the rule, of course, would not be enforced. Again, by ordinary and established practice is meant the established practice of the physician's own school, and he is only expected faithfully to treat the patient according to the recognized rules of his particular school. Although someone else might think that some other school of medicine was better, his skill is to be judged by the school of practice to which he belongs and according to the avowed system which he professes. Of course, the law requires him to come up to at least the average standard of the school to which he adheres. By school in this sense the law means generally recognized method of treating disease or injury. A person who attempts to practice as a clairvoyant, or who attempts to heal disease by means of some occult influence exercised by him or some mental intuition received by him when in an abnormal condition, cannot excuse himself on the ground that he is practicing according to his school, but must take the risk if he fails to exercise the skill ordinarily possessed by a reputable practicing physician or surgeon.

In some states it has been held that if the service rendered was gratuitous the physician is not held to the exercise of so high a degree of care, but the rule in Illinois is that if a person holds himself out to the public as a physician he will be held to the exercise of ordinary care and skill in every case, whether he receives a fee for his service or not.

It is perhaps well to say, in connection with the rule of ordinary care above laid out, that the law imposes on the person making the complaint the duty of showing that he also exercised reasonable and ordinary care in carrying out the physician's instructions and in attempting to heal himself. Any failure in this regard on his part, if shown in an action, is a complete bar to his right of recovery in law; that is to say, in order to maintain his action, he must show two things: first that he was not guilty of any failure to exercise ordinary and reasonable care in carrying out the instructions of the physician and in attempting to cooperate with the physician for his own recovery, and second, he must show that the physician failed to exercise ordinary and reasonable care and skill in the conduct of the case; the burden of proof rests on the complainant in both of these respects.

164 Dearborn Street.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Ninth Month—Fourth Weekly Meeting

Diseases of the Nervous System (Continued)

Tuberculous Meningitis

Pathology: Tubercle, size, number, locations. Changes in pia and dura, in brain substance. Character, quantity and location of exudate. Association of meningitis with other tuberculous lesions. Relation of symptoms to lesions.

Symptoms: Prodromata, onset, duration of early symptoms. Convulsions, stupor or coma, headache, crying, muscular rigidity, eye symptoms, gastro-intestinal symptoms. Pulse, temperature and respiration. Second stage: Increase of early symptoms, paralyses, eye symptoms, mental symptoms, respiration. Duration of second stage. Third stage: Coma, eye symptoms, pulse, temperature, respiration. Variations in course of disease at different ages. Duration and prognosis.

Chronic Basilar Meningitis (Still)

Etiology: *Diplococcus intracellularis.* Syphilis.

Symptoms: Previous history. Onset, opisthotonos, hydrocephalus, muscular rigidity. Eye symptoms. Mental condition. Course and duration.

Chronic Internal Hydrocephalus

Etiology: Primary, congenital, cases; heredity, syphilis, rickets. Secondary; tumor, meningitis.

Pathology: Quantity, physical and chemical characteristics of fluid. Secondary changes in fluid. Changes in brain substance, in ependyma, in bony structures.

Symptoms: Size of head, character and rate of enlargement. Sutures and fontanelles. Motor symptoms. Eyes, mental symptoms. Clinical varieties.

Monthly Meeting

The Diagnosis and Treatment of Congenital Heart Disease.
The Treatment of Convulsions in Infants and Children.
The Early Diagnosis of Tuberculous Meningitis.
The Diagnosis and Treatment of Cerebrospinal Meningitis.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Regular, Little Rock, May 9. Sec., Dr. F. T. Murphy, Brinkley; Homeopathic, Little Rock, May 9. Sec., Dr. P. C. Williams, Texarkana; Eclectic, Little Rock, May 9. Sec., Dr. G. A. Hinton, Hot Springs.

Florida: Regular, Tallahassee, May 8-9. Sec., Dr. J. D. Fernadez, Jacksonville; Eclectic, Lakeland, May 1-3. Sec., Dr. Hiram J. Hampton, Tampa.

Georgia: Homeopathic, Atlanta, May 2. Sec., Dr. R. E. Hinman, 153 Whitehall St., Atlanta.

Illinois: City Hall, East St. Louis, May 3-5. Sec., Dr. J. A. Egan, Springfield.

Kentucky: The Armory, Louisville, May 31. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: Regular, New Orleans, May 18-20. Sec., Dr. A. B. Brown, 108 Baronne St.; Homeopathic, New Orleans, May 1 Sec., Dr. John T. Crebbin, 1207 Maison Blanche Building.

Massachusetts: State House, Boston, May 9-11. Sec., Dr. Edwin B. Harvey, Room 159, State House.

Mississippi: Jackson, May 9. Sec., Dr. S. H. McLean.

Nebraska: State House, Senate Chamber, Lincoln, May 24. Sec., Dr. E. Arthur Carr, 141 S. 12th Street.

Nevada: Carson City, May 1-3. Sec., Dr. S. L. Lee.

New York: May 23-26. Mr. Harlan H. Horner, Chief of Examinations Division, Department of Education, Albany.

Wisconsin: Milwaukee, May 24-26. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

New Mexico January Report

Dr. J. A. Massie, secretary of the New Mexico Board of Health and Medical Examiners, reports the written examination held at Santa Fe, Jan. 9, 1911. The number of subjects examined in was 11; total number of questions asked, 90; percentage required to pass, 75. The total number of candidates examined was 2, both of whom failed. Fourteen candidates were licensed on presentation of satisfactory credentials. The following colleges were represented:

FAILED

College	Year Grad.	Per Cent.
Tennessee Medical College	(1906)	44
Gate City Medical College	(1909)	35.4

LICENSED ON PRESENTATION OF SATISFACTORY CREDENTIALS

College	Year Grad.
Columbian University, Washington, D. C.	(1894)
Georgetown University	(1908)
Louisville and Hospital Medical College	(1908)
University of Louisville	(1905)
Michigan College of Medicine and Surgery	(1897)
University Medical College, Kansas City	(1901) (1909)
American Medical College, St. Louis	(1891)
New York University Medical College	(1884)
Toledo Medical College	(1907)
[illegible]ge, Philadelphia	(1906)
[illegible]	(1904)
Vanderbilt University	(1906)
Medical College of Virginia	(1899)

District of Columbia January Report

Dr. George C. Ober, secretary of the Board of Medical Supervisors of the District of Columbia, reports the written examination held at Washington, Jan. 10-13, 1911. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. The total number of candidates examined was 7, of whom 6 passed and 1 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
George Washington University	(1909)	78.7
Johns Hopkins University	(1910)	85.7
University of Michigan, Dept. of Med. and Surg.	(1898)	79.2
St. Louis College of Physicians and Surgeons	(1910)	76.9
Jefferson Medical College	(1909)	84.4
University of Virginia	(1910)	82.5

FAILED

College	Year Grad.	Per Cent.
Jefferson Medical College	(1908)	69.3

Book Notices

DEUTSCHES ARZNEIBUCH. Fünfte Ausgabe 1910. Paper. Price 3.90 marks. Pp. 680. Berlin: R. v. Deckers Verlag, G. Schenck, Königlicher Hofbuchhändler, 1910.

It has frequently been asserted that pharmacopeias, more than any other publication, reflect the ideals and the practices of the medical profession of the time and the country for which they are published. Accepting this statement as based on fact we can readily appreciate the reasons why this, the fifth, edition of the "German Medicine Book" has been so anxiously awaited by pharmacists and by teachers of materia medica. As indicated by the absence of the Latin synonym accompanying the official title in former editions, the present book is thoroughly German and, in fact, is the first of the several editions to be compiled entirely under government supervision, in the division on materia medica of the "Reichs Gesundheitsamt."

Because of the many innovations embodied in this edition the book is being liberally discussed and promises to prove the forerunner of a new era in medicine and pharmacy by indicating how the medicaments used by the physician can and should be controlled to insure their purity and efficiency. To appreciate this more fully it should be understood that in Germany the object and the use of the pharmacopeia is somewhat sharply defined and the book is recognized primarily as one of directions for the apothecary in the manufacture and control of medicaments designed to be used on physicians' prescriptions.

One of the more important innovations is the liberal recognition that has been accorded to perpetually protected or trademarked names. The German government by introducing proprietaries into its pharmacopeia not only gives due credit to German chemical industries for the introduction of new remedies but also safeguards the interests of the public by requiring that the medicaments advertised and sold under recognized trade names must conform to pharmacopeia requirements. Where a scientific designation is more convenient or in general use, it has been adopted as a chief title followed by the trade name.

In addition to the rather liberal recognition given to new remedies, a number of general descriptions or class headings have been adopted. These have long been a distinctive feature of the German Pharmacopeia and are of great practical value, particularly in a book which. like the one under discussion is designed to serve as a guide to the apothecary in the compounding of prescriptions and not to be a book of standards for regulating the trade in drugs and medicines generally. The new pharmacopeia contains a total of forty-four titles more than the Pharmacopeia Germanica IV and this difference is largely made up of new remedies and general headings.

For the medical practitioner in countries other than Germany and more particularly for the medical practitioner of the United States this edition of the German Pharmacopeia is an indication of the services that can and should be rendered by the pharmacist in controlling and safeguarding the identity and purity of the drugs used in the treatment of diseases. With the practice of pharmacy in this country based on scientific training and the pharmacist able to control and to guarantee the purity and efficiency of the drugs he dispenses there would be little or no need for special brands of medicines and absolutely no need for the many ready-made mixtures of the patent medicine type now prescribed by physicians.

I. REPORT ON AN OUTBREAK OF TYPHOID FEVER AT OMAHA, NEB. (1909-1910). By L. L. Lumsden. II. THE WATER SUPPLY OF WILLIAMSON, W. VA., AND ITS RELATION TO AN EPIDEMIC OF TYPHOID FEVER. By W. H. Frost. Hyg. Lab. Bull. 72, November, 1910, U. S. P. H. and M.-H. S. Paper. Pp. 94, with illustrations. Washington: Government Printing Office, 1910.

L. L. Lumsden reports an investigation of an epidemic of typhoid in Omaha, lasting from November, 1909, to March, 1910, a brief account of which was given in THE JOURNAL, May 7, 1910, p. 1555. After eliminating, through a study of the statistics of 105 cases, such sources of infection as milk, ice, etc., a detailed account is given of the probabilities of water as the carrier. The public supply is obtained from the Missouri River at two points, one at some distance above Omaha, and the other at the city. The water is stored for about six hours, and alum is added for a coagulant. Sewage enters the river about 8 miles above the city intake, as well as at a number of places along the banks at no great distance from the city. The number of cases of typhoid fever among persons using water from this latter intake was disproportionately large. Analyses are given showing that the water from both intakes was badly polluted in spite of the attempted purification. A study of climatic conditions led the author to believe that during the fall of 1909 the river was subject to more than the usual degree of pollution. Infected water is regarded as without doubt the source of the outbreak. Recommendations are made that the river be more carefully guarded against dangerous pollution, and that the water be treated by mechanical filtration followed by the addition of hypochlorite of lime.

W. H. Frost, in the same bulletin, reports an investigation made during May and June, 1910, of an epidemic in Williamson, W. Va., which started about Nov. 1, 1909, and continued for several months. The general sanitary condition of the town and the water-supplies was carefully studied. A high power of pollution was found to exist not only in the town water but also in a number of shallow wells, which are in rather general use as the public supply is of a disagreeable character, being obtained from a river which receives washings from a coal mine located in one part of the town. Frost believes that the original source of the epidemic was the water, which became more than usually polluted on account of the low condition of the river in the fall of 1909 and the many possible sources of contamination which exist along its banks. A normal condition was resumed in January, but typhoid fever still continued. This is believed to have been due to contact infection. A study of the statistics of the later cases showed that many had to come in contact with previous cases. More evidence is furnished for this belief by the facts that in a majority of instances no efficient means of disinfection were used, and that great opportunity exists for contamination of wells, owing to the generally poor sanitary arrangements.

Recommendations are made: (1) that the public supply be purified with hypochlorite of lime or ozone, a new supply being considered impractical on account of the lack of sources in the region; (2) that methods of sewage disposal be improved; (3) that more careful disinfection be employed; (4) that the board of health supervise the sale of milk and other foods.

Plastic and Cosmetic Surgery. By Frederick Strange Kolle, M.D., Fellow of New York Academy of Medicine. Cloth. Price, $5. Pp. 511, with 522 illustrations. New York: D. Appleton & Co., 1911.

The author has brought together in this work a rather full statement of the plastic surgery of the head and face. Preliminary to this he takes up the principles and the practical details of operations in this field, and thus in reality gives the first 100 pages to a consideration of minor operative surgery. In successive chapters he considers the plastic surgery of the eyelids, the ears, the lips, the mouth, and the cheeks; and these chapters are good. They represent a grouping of the subject of plastic surgery of the face and head that is valuable to anyone looking for practical knowledge in this field. The plastic and cosmetic surgery of the nose is taken up after considering paraffin prosthesis.

To the subject of subcutaneous hydrocarbon prosthesis Kolle gives 130 pages, in which the subject is very fully considered. It is a very useful presentation of the subject, to which anyone may turn with satisfaction for information. The author is a very enthusiastic advocate of paraffin prosthesis for the correction of defects. In its use for the correction of serious anatomic defects or deformities we have no criticism of his position to offer, but its use for the removal of trivial cosmetic defects—to smooth out wrinkles, to fill out hollow necks or flabby cheeks, for decorative purposes, for example—we believe should be very strongly condemned. Those of us who are seeing the hyperplastic tumors sometimes following these injections are impressed with the fact that to justify putting a mass of paraffin into the connective tissue there should be a more important indication than the smoothing out of a wrinkle or the improvement of the contour of the alæ nasi, particularly as in making the change one gives the injected tissue all of the motility of a graven image.

On the whole the work will be found a useful treatise on the subject of which it treats.

The Health Index of Children. By Ernest Bryant Hoag., M.A., M.D., Medical Director of Berkeley Schools. With Prefatory Note by Frank F. Bunker, Ph.B., Superintendent of Berkeley Schools. Cloth. Price, 80 cents. Pp. 188, with illustrations. San Francisco: Whitaker & Ray-Wiggin Co., 1910.

Dr. Hoag has that happy and all-too-rare ability to address the layman in the layman's own language without in the slightest degree compromising scientific accuracy. Perhaps a single exception may be found in the title of this book itself, which fails to convey to the uninitiated its real purpose and nature as the title of a popular treatise really should.

"The object of this little manual," to quote the author himself, "is to show teachers and parents how to detect easily those ordinary physical defects of the child which bar his progress in school and life, and to suggest means by which such defects may be removed and good health afterward maintained. Incidentally, it may prove of some value to physicians who are for the first time applying themselves to this special sort of public health work." The book contains just such practical information as every parent, teacher and school inspector should have to enable them to detect in their incipiency such defects as adenoids, deafness, eye-strain, nervousness, defective teeth, and to take the proper measures to have them remedied before irreparable damage has been done. The book contains admirable diagnostic tables, few but well-chosen photographs, clean-cut simple summaries, curves and diagrams, all so plain that any mother of average intelligence can understand them. In the present far-reaching tendency to take an eager public into the confidence of the medical profession, this little book should take a prominent position because it deals with those at the threshold of life where defects can be prevented or easily remedied. Such books are the natural antidote to the isms that have grown fat on ignorance; and we wish that every mother and father and school teacher could "read, mark, learn and inwardly digest" this little volume.

Practical Physiological Chemistry. By R. H. Aders Plimmer, D.Sc., Assistant Professor of Physiological Chemistry, University College, London. Cloth. Price, $1.80. Pp. 270, with 49 illustrations. New York: Longmans, Green & Co., 1910.

In this book an attempt is made to cover too much ground in a small space, and as a result both accuracy and clearness suffer. Thus, in the first thirty pages the student is informed on no greater number of subjects than qualitative and quantitative organic analysis, distillation, filtration, extraction, melting-point determination, boiling point determination, three methods of molecular weight determinations and discussions under headings such as "Constituents of a Cell" and "Life Cycle of the Elements." The remainder of the text is devoted to brief considerations of the most elementary features of organic chemistry and more or less detailed treatment of the biologically important constituents of protoplasm, the latter being considered from the qualitative and quantitative points of view. Statements such as that the constitution of d-glucose, d-mannose, d-galactose and d-fructose "is proved by their reduction to the corresponding hydrocarbon hexone and by oxidation" are very misleading. There is also at least one important omission. The pyrimidin bases are not mentioned; the student is simply told in different parts of the text that nucleic acid contains pentose, guanine and adenine, that it is obtained from nucleoprotein and that the latter contains phosphorus in the nuclein portion.

Diagnostik der Nervenkrankheiten. Von Dr. L. E. Bregman, Oberarzt am städtischen jüdischen Krankenhaus in Warschau. Mit einem Geleitwort von Dr. H. Obersteiner in Wien. Paper. Price, 12 marks. Pp. 535, with 193 illustrations. Berlin: S. Karger, 1911.

Of the books on the diagnosis of nervous diseases which have hitherto appeared in English or German, we know none which approaches the subject from the viewpoint of semeiology, a method which has long been in vogue among the French. It is this method which is successfully followed by Bregman. In sixteen short chapters he approaches diagnosis from such symptom-groupings as paralysis of motion, of sensation, the special senses, reflex and speech disturbances and other symptom-complexes, with, in addition, a chapter on the diagnosis of psychic disorders. In a work including so much, we might expect a mere collection of tabulated diagnostic aids. The author gives, however, a full and concise account of everything important in the clinical diagnosis of nervous diseases. To summarize, it may be said that all topics have been given due attention and are entirely up to date. This manual is the product of one who is not only well trained in the best methods of neurologic examination, but who can also explain them and teach how to correlate the findings. The book on the whole is a distinct gain to modern neurologic literature.

A Study of the After-Results of Abdominal Operations on the Pelvic Organs. Based on a Series of 1,000 Consecutive Cases. By Arthur E. Giles, M.D., Surgeon to the Chelsea Hospital for Women. Cloth. Price, 10 shillings 6 pence. Pp. 251. London Baillière, Tindall & Cox, 8 Henrietta St., Covent Garden, 1910.

The author analyzes the after-results in 1,000 cases of pelvic operations. Only one who has attempted to follow up patients for some time after operations will appreciate the immense amount of labor it has cost the author to follow out and determine the present condition of 1,000 patients who had been operated on for pelvic diseases during the past several years. It too often happens that the patient who escapes from the hospital with her life is immediately reported as having been cured of her trouble; or, if the case is reported later, it is assumed that the patient is well simply because she has not been seen or heard of since the operation. It is only by the painstaking method adopted by Dr. Giles that the defects, as well as the advantages, of a given operation become apparent. In the first part of the work the author gives in detail the present condition of the patients, classified according to the particular operation performed, and in the second, a brief clinical history of each case.

The author is to be commended for the earnest effort made and congratulated on the excellent results obtained.

Handbook of Treatment for Diseases of the Eye (Ophthalmic Therapeutics). By Dr. Curt Adam, Assistant-Surgeon in the I. University Clinic for Diseases of the Eye, Berlin. With a Preface by Prof. von Michel, Berlin. Translated from the Second German Edition (1910), by William George Sym, M.D., F.R.C.S.Ed., and E. M. Lithgow, M.B., F.R.C.S.Ed. Cloth. Price, $2.50. Pp. 264, with 36 illustrations. New York Rebman Co., (1911).

The second edition of this small manual, as its title indicates, contains the essentials of ophthalmic therapeutics. It is evident that a full account of this important subject cannot be crowded into so small a space, yet the book contains a surprisingly large amount of information. While it is merely a compend, we believe that it stands as a series of useful, predigested facts that will be more readily absorbed by the general practitioner and by the student of ophthalmology than larger and more imposing treatises. The space (20 pages) set apart for the consideration of refraction and the prescribing of spectacles seems unduly restricted, at least to our American notions, but probably from the German point of view it is sufficient. The work has a place in ophthalmic practice if for no other reason than that judiciously written compendiums on special subjects are always of value to those who do not make a particular study of the medical department in question.

HERNIA. Its Cause and Treatment. By R. W. Murray, F.R.C.S., Surgeon, David Lewis Northern Hospital. Second Edition. Cloth. Price, $1.75 net. Pp. 184, with 62 illustrations. Philadelphia: P. Blakiston's Son & Co., 1910.

In explanation of the existence of this little volume the author says: "My reasons are that I believe the explanation offered in the following pages as to the cause of hernia to be the true explanation and the results I have obtained by a simple method of operating are extremely encouraging." The author is a firm believer in the so-called saccular theory of the cause of hernia, which was so well presented some time ago by Mr. Hamilton Russell of Melbourne. Most surgeons who have given the subject much study are now convinced that the great majority of hernias are due to congenital defects in the shape of preformed sacs regardless of the age at which the rupture becomes evident. Murray's method of operating does not differ materially from the standard operation generally in use to-day. He merely emphasizes again the necessity of complete removal of the sac whenever that is possible.

LE TRONC CŒLIAQUE. Par Pierre Descomps, Prosecteur des Hôpitaux. Travail de l'Amphitheatre d'Anatomie des Hôpitaux. Recherches d'Anatomie Chirurgicale sur les Artères de l'Abdomen. Cloth. Price, 10 francs. Pp. 205, with 97 illustrations. Paris: G. Steinheil. 1910.

The amount of surgery being done in the upper abdomen on the organs which receive their blood-supply from the celiac axis makes it incumbent on the surgeon to have an accurate knowledge of these vessels, their surgical relations, anastomoses and their most common deviations from the normal. In order to be able to present this subject clearly, the author made a careful study of this region in fifty cadavers. The arteries were injected through one common iliac after ligating the opposite common iliac and the aorta just below the diaphragm. The findings in the fifty cases are well illustrated by ninety-seven figures, each of which is thoroughly described in a voluminous text of about 200 pages. The literature is also well covered and the findings of other anatomists are recorded, where these relate to deviations from the accepted normal. The work is an excellent study in descriptive and surgical anatomy and has a decided practical value.

HISTORY OF ANTHROPOLOGY. By Alfred C. Haddon, M.A., Sc.D., F.R.S., Fellow of Christ's College, University Reader in Ethnology, ...idge. With the Help of A. Hingston Quiggin, M.A., Formerly ...ham, Cambridge. Cloth. Price, 75 cents. Pp. 206, with ... New York: G. P. Putnam's Sons. 1910.

Thus the work will be of service as a work of reference, whether or not one accepts the author's conclusions. Its perusal will do good, as no doubt many people eat too much meat and too little of some valuable vegetable products.

HUGHES' PRACTICE OF MEDICINE. Including a Section on Mental Diseases and One on Diseases of the Skin. Revised and enlarged by R. J. E. Scott, M.A., B.C.L., M.D., Attending Physician to the Demilt Dispensary. Tenth Edition. Leather. Price, $2.50 net. Pp. 878, with 63 illustrations. Philadelphia: P. Blakiston's Son & Co. 1911.

This old standby for the student and the general practitioner is evidently keeping up the popularity it has enjoyed for so many years. This popularity is due to the fact that the book gives practical discussions of diseases as briefly as is consistent with the subject, theories being eliminated. The present edition has been brought thoroughly up to date, all necessary changes having been made to adapt it to modern medicine. Many of the articles have been practically rewritten, and some new ones added.

Medicolegal

License Rights of Certain Practitioners—Powers and Duties of State Board

The Supreme Court of Idaho holds, in Vadney vs. State Board of Medical Examiners (112 Pac. R. 1046), that, under the provisions of Section 1298 of the Revised Statutes of 1887, no person was permitted to practice medicine or surgery *in that territory (now state) who had not received a medical* education and a diploma from some regularly chartered medical school having a bona-fide existence at the time the diploma was granted, and when it appeared that the applicant for a license to practice medicine and surgery in the state was engaged in the practice of his profession under the provisions of the Laws of 1887, and had complied with all of the provisions of section 5 of the Act of 1899, it was the duty of the State Board of Medical examiners to issue to him a license to practice medicine and surgery in Idaho.

A diploma from a regularly chartered medical school, which has a bona-fide existence at the time the diploma was granted, and a compliance with the provisions of section 1298a and 1298b of the Revised Statutes of 1887, with reference to being identified and filing a copy of the diploma, was all the proof that the statute required at that time of the applicant's having a medical education, and under the act of 1899 the medical board had no authority to require any other or further evidence of the fact.

The State Board of Medical Examiners, under the law of 1899, had no authority to refuse a license to an applicant who was engaged in the practice of medicine and surgery under the Laws of 1887, on the ground that the college issuing the medical diploma under which he was practicing was *not* a "reputable college of medicine in good standing." The board had a right to determine the question about the college issuing the diploma being a "reputable college of medicine in good standing" under the Act of 1899, where the applicant had not been practicing medicine and surgery under the Act of 1887; but when the applicant had been practicing under the Laws of 1887, and made application under the fifth section of the Act of 1899 for a license, the board had no authority whatever to determine that question. If the plaintiff had a diploma from a regularly chartered medical school that had a bona-fide existence at the time the diploma was granted, that was all that was necessary, so far as the diploma was concerned.

If the plaintiff's application was not properly verified, it was the duty of the secretary of the board to return it to the applicant for verification, and if the persons who certified to the good moral character of the plaintiff were not satisfactory, the plaintiff ought to have been notified of that fact and given an opportunity to furnish the names of other persons who would certify to his good moral character, if he could.

Under the provisions of section 9 of the medical law of 1899 there is no provision for an appeal from an order of the State Board of Medical Examiners refusing to grant a license to an applicant; but said section contains a provision whereby the proper court may review by certiorari certain proceedings of said board.

Relative Weight of Evidence of Attending Physicians

The Supreme Court of Louisiana holds, in the personal injury case of Rickerson vs. Town of Minden (53 So. R. 667), that the testimony of a physician who attended a person immediately after an accident is of more weight on the question of the seriousness of the injury than that of a physician who attended the injured person a year after the accident, for other causes and conditions might have intervened during the year.

Evidence of Fetus Being Quick

The Supreme Court of Kansas says that it was urged in the criminal abortion case of State vs. Hatch (112 Pac. R. 149) that only the mother or persons who have placed their hands on her body and felt the independent motion of the fetus can know whether or not it is quick. But if this were adopted as the iron-clad rule of evidence in such cases, the statute defining the crime of abortion would be practically impossible of enforcement after the death of the mother. The court prefers to hold that where physicians testify, as experts, to the measurements and appearance of a fetus found by them in the body of a deceased woman, and that from such measurements and appearance they each had an opinion as to the age of the fetus and as to whether the woman at her death was quick with child, it is competent to allow such witnesses to testify each to his opinion.

Proof of Amount of Earnings of Physician Not Necessary

The Court of Appeal of the Second District of California holds, in Washington vs. Pacific Electric Railway Co. (112 Pac. R. 904), that, in an action brought by a physician to recover damages for personal injuries, including damages for loss of earning power, the right to recover the latter is not dependent, under the decisions of that state, on proof of some specific or particular sum of money that had been or was at the time of the injury being earned by the plaintiff, where the evidence shows that the plaintiff was a practicing physician and several witnesses testify to having been attended at different times by the plaintiff professionally.

No Illegal Discrimination Against Hospital

The Supreme Court of California reverses a judgment recovered by the plaintiff, in Union Labor Hospital Association vs. Vance Redwood Lumber Co. and others (112 Pac. R. 886), an action brought against the defendant named and six other lumber companies to enjoin them from conspiring and combining together to vex, injure and destroy the hospital business of the plaintiff. The defendants, the court says, compelled every employee to consent to the deduction of $1 from his monthly wage, 12½ cents of which went into a contingent fund to help needy employees who might be injured and 87½ cents of which went to a hospital for an employee's ticket that entitled him to medical and surgical care and attendance in case of injury. The occupations of their men were dangerous. That provision should be made for the medical and surgical care of the men injured was most proper. No objection was made to this, nor to the means adopted to effectuate it, saving that the plaintiff contended that because its hospital was not on the list of enumerated hospitals from which the employees were authorized to make a selection, a species of unlawful discrimination was practiced against it. But the court does not agree with that, or, in other words, that there was an illegal boycott against the continuance of which the defendants should be enjoined.

There being no contractual relations between the plaintiff and the defendants, the defendants, individually or in combination, were under a duty only to refrain from inflicting a legal wrong on the plaintiff. Unquestionably there was nothing illegal in the measures employed by the defendants. The suasion or intimidation or coercion was purely moral, and went no further on the part of the defendants than a refusal to employ or to retain in their employ any one unwilling to comply with their hospital regulation. This was purely a matter between employer and employee, and, where no contract between them stands in the way, it is the unquestioned right of an employer to discharge at his pleasure, or to impose conditions on the retention of the employee in his employment.

The court is unable to perceive where any element of monopoly entered into this case, as the plaintiff claimed. The defendants had the undoubted right to deal with any hospital which they might select. In fact, they were dealing with four, and they were not even prohibiting their men from engaging the services of the plaintiff. That is, the defendants insisted merely that the employee buy a ticket in one of their designated hospitals. Then he was at liberty to buy an additional ticket in the plaintiff's hospital, though, in the nature of things, an employee having purchased a ticket in another hospital would not be likely to lay out more money for such a purpose. And since the acts of the defendants were within their legal rights, the motive for those acts was not a subject of inquiry.

Liability of Company Requiring Injured Person to be Taken to Physician

The Supreme Court of New Jersey holds, in Perkins vs. Trenton Street Railway Co. (78 At. R. 666), that where a printed rule of a trolley company required the conductor of a car in case an accident should occur to take the injured person to a physician, and the motorman met with an accident by which his leg was crushed, and the conductor telephoned to the plaintiff, a physician, who came and amputated the limb, the company was liable on contract to the physician for the value of the service thus rendered.

The court says that the requirement of the rule that when an accident occurs, and necessity for it exists, the conductor shall take the injured person to a physician is meaningless, unless it means that the physician is to render the professional aid necessitated by the accident. The court thinks that this is its meaning and that services of such a character when so rendered are rendered to the company through its duly authorized agent. The authority to take the injured person to the physician of course carries the authority to call the physician to the injured person.

The rule or instruction not making any distinction as to cases of accidents for which the company is not liable, the court, on reflection, thinks that no such distinction can be made in view of the ground on which the rule or instruction itself must be supported as a reasonable exercise of corporate regulation. The directors of the company will be presumed to have framed and promulgated this instruction in the interest of the stockholders. From this point of view they may well have considered that for every injury resulting from an accident in their cars a lawsuit is possible, in the course of which their liability would for the first time be authoritatively determined. If liable they may be deemed, from their knowledge of human nature, to know that the damages assessed by the jury would as a rule be largely enhanced by any show of inhumanity toward the plaintiff at the time of his injury, or any lack of immediate care for him at that critical juncture, and also that humane aid promptly secured by the company would be a circumstance likely to affect the jury favorably. The directors also knew, unless blind to the details of their business, that it is of the utmost importance in litigated accident cases that the medical witness who first sees and ministers to the injured person should not be one selected and paid (or to be paid after the suit) by such person, and still more that such witness shall not be selected by the attorney who prosecutes the suit for damages. A rule that would in all cases tend to secure unbiased testimony on this important feature of every such litigation would be an exercise of sound discretion by the directors.

This answers the objection that it is no part of the directors' duty to provide medical attendance for persons for whose injuries the company is not liable. For such liability cannot be determined at the instant of the accident, and that is the instant at which the conductor is required to act. So that in view of the reason suggested for such rule it would be a sound exercise of discretion for the directors to incur the slight expense in those cases in which it was ultimately determined that the company was not liable in view of the far greater importance of the results flowing from such rule in cases where the question of damages was involved. For the same reason, and to the same end, the rule should not be interpreted, or rather frustrated, by making the conductor pass as judge and jury on the law and facts of an accident at the instant of its occurrence as the basis of his private judgment as to whether or not it came within the rule that prescribed his duties in case of an accident.

Regarding the case, therefore, as one in which the injured person was guilty of contributory negligence, or such as would bar his right of recovery against the company, the court thinks that that circumstance affected neither the interpretation of the company's rule nor its legal effect on the agency of the conductor.

The President, Dr. C. B. Longenecker, in the Chair

SYMPOSIUM ON NEPHRITIS

The Chemistry of Nephritis

Dr. Howard T. Karsner read a paper reviewing the status of the chemistry of nephritis in reference to the metabolism and the urinary changes in the various forms of non-suppurative inflammations of the kidney and presenting the chemistry of uremia and edema. The paper will appear in The Journal.

Symptomatology and Diagnosis of Nephritis

Dr. John F. Roderer: Bright's disease in my opinion should be divided into: (1) parenchymatous nephritis, (2) the so-called chronic interstitial nephritis. Parenchymatous nephritis, which is essentially a disease of the kidneys, is divided into the acute and chronic forms, and the principal diagnostic symptoms are connected with the urine. The diagnosis of chronic interstitial nephritis can be made, I believe, without any examination of the urine, by the continued high blood-pressure caused by the diseased blood-vessels, and the altered function in the heart, eye, kidneys and other organs, the result of the diseased arteries and high-blood pressure. I am convinced that the condition called chronic interstitial nephritis is not essentially or primarily a disease of the kidneys, but an inflammatory disease of the arteries, possibly principally the terminal arteries. Chronic arterial fibrosis would be a better term. It is true that in this disease the kidneys become affected, but so may every other organ of the body. I am of the opinion that the retention of urea in the system in this disease acts only as an overdose of opium, and that uremia is given credit for some of the symptoms to which it is not entitled. The disease of the blood-vessels and the high blood-pressure will explain all the other symptoms. The brain as well as the kidneys suffers in this disease. The heart suffers most. The disease is insidious in its onset, and may exist for years without giving rise to serious symptoms. A patient may consult the physician for indigestion, headache, failing vision, shortness of breath on exertion, or a general lassitude, and any one of these symptoms may be the first evidence of the disease. Given any one of these symptoms in a patient past middle life engaged in mental labor, and inclined to worry, a thorough examination should be made. The eye is the one organ which will confirm the existence of this disease long before the evidence is shown by the kidneys. There may be normal vision with the presence of retinal lesions.

Operative Treatment of Bright's Disease

Dr. Morris Booth-Miller: In my opinion, the question resolves itself somewhat as follows: First, there is no scientific justification for the assumption that surgery, or anything else, can cure nephritis once it is established. Second, the majority of the theories which have been advanced to warrant surgical interference have not been very convincing, to say the least. A constantly growing mass of clinical data, which is deserving of the closest scrutiny, tends to show, however, that the physiologic cure of Bright's disease through remission may be brought about by operation. Despite an immediate mortality of about 30 per cent., and a mortality of 44 per cent. within a short period, the results of the operative treatment have been hopeful when the desperately ill condition of many of these patients is taken into consideration. The reported cases, now running into many hundreds, show a striking number of recoveries, some of which can only be described as brilliant, and it is not surprising that nearly three-fourths of the surgeons who have expressed opinions are favorably disposed and satisfied with their results. I believe that nephrotomy in these cases does good and often saves life, because it does, and does abruptly and thoroughly, certain things which are within the mental horizon of every medical student whenever he thinks of nephritis. I believe that cutting down on the kidneys accomplishes all the purposes of cupping and bloodletting, and does it better, because it tends to relieve the disturbance at its focal point. Just as in intestinal obstruction the sympathetic nerve impulses create violent peristalsis to overcome the obstruction, so we may have in anuria and uremia intense local vasomotor efforts to overcome the renal block. Furthermore, the removal of the capsule seems wise. No man can say just what part is played in a case of suppression by the edema within the kidney itself, and decapsulation certainly offers an outlet. For this reason I believe with Harrison that drainage should always be done in these cases. There may be other explanations for the value of surgical interference in restoring renal equilibrium based on more precise knowledge of urinary physiology, but for the present these seem sufficient. It is in cases in which hypertension, local and general, and edema are the predominant phenomena that the most successful results have been obtained, while the least satisfactory subjects for the knife have been those whose kidneys were caught in the death-grip of interstitial change. Particularly apt has been the operation in saving life in the severe form of nephritis complicating and following the actue exanthemata, of which scarlatinal nephritis may be mentioned as a type. The results in chronic parenchymatous and, to a minor extent, in diffuse nephritis, have been less satisfactory. Those cases in which the cardiovascular changes are marked are the least favorable of all. Nephritis is and must remain a medical entity, and it is not until medical measures have been given a fair trial and have failed that we are justified in considering surgery. When that time comes, the following fairly well-defined principles may be borne in mind for guidance in the individual case: First, operation may be hopefully done in acute nephritis; second, young patients are the best subjects; third, there is sound reason for operating for anuria or uremia occurring in chronic nephritis; fourth, operation may be resorted to as a last desperate chance in any form of nephritis.

DISCUSSION

DR. HENRY K. PANCOAST: The use of the x-ray examination in connection with kidney disease is rather closely limited to the diagnosis of calculus in the kidney or ureter, and to the determination of alterations in the position or size of the kidney. Considering the number and variety of the factors that may affect the accuracy of the x-ray diagnosis, it is almost remarkable that the percentage of error is as low as it is. Fortunately, the most frequent sources of trouble may be overcome, guarded against or eliminated. The various sources of error may be classified in somewhat the following manner: Obesity; inadequate preliminary preparation of patient; conditions of the abdomen or pelvis which offer shadows of unusual density; surgical dressings, drainage tubes, etc.; the presence of unusual conditions causing shadows that may simulate those of stones in the kidney or upper portion of the ureter; misplaced or supernumerary kidneys or ureters; conditions or objects which may, by their shadows, lead to error or confusion in the diagnosis of calculus in the lower portion of the ureter; certain anatomic structures, as in the case of stones obscured by the shadows of the pelvic bones and the lower ribs; the consistency of the calculus; lack of adequate clinical knowledge of the case on the part of the examiner. The fact should not be overlooked that it is possible for a stone to be present without producing a perceptible shadow on the radiograph, because pure uric-acid calculi possess such a slight degree of density that they may not produce a distinguishable shadow in any but a thin individual. The modern technic of the examination for renal calculus requires some knowledge of the clinical aspect of the case on the part of the examiner, and the physician who refers the case adds to the possibility of error in failing to supply the necessary data. As a further safeguard against mistakes, it is wise to confirm the findings of a positive examination before submitting the patient to an operation for the removal of a calculus.

DR. B. A. THOMAS: Until we learn more about the kidney along the line of physiologic chemistry, I think not much advance will be made in the investigation of this disease.

14. Abstracted in THE JOURNAL, Oct. 1, 1910, p. 1220.

15. **Blood Findings in Lymphatic Leukemia.**—In Woodward's case the left axillary lymph nodes became swollen and suppurated three years ago. They were incised; following this they remained enlarged. One year ago the glands of the right axilla became enlarged also, and soon after those of the neck and groin began to enlarge. In April, 1909, the patient, a woman of 65, was confined to bed for one week, with fever ranging from 100 to 101 F. She complained chiefly of weakness. On May 23, 1909, a blood examination gave the following results: hemoglobin, 48 per cent. (Dare); reds, 2,880,000; whites, 781,000; differential count of 1,000 white cells gave small lymphocytes, 98.6 per cent., 770,060 per c. mm.; large lymphocytes, 0.9 per cent.; 7,030 per c. mm.; polynuclear nutrophiles, 0.5 per cent., 3,900 per c. mm. No nucleated reds were seen in counting 1,000 whites, but careful later search showed a very few. Color index was 0.84. Fowler's solution was started at once, 3 drops, later increased to 10 drops, being given, thrice daily. December 10, 1909, just two weeks before death the blood examination was as follows: hemoglobin, 35 per cent. (Dare); reds, 2,600,000; color index, 0.67; whites, 1,406,000. Differential count of 1,000 whites: small lymphocytes, 7.8 per cent., 109,670; polymorphonuclear neutrophiles, 1.3 per cent., 18,280; transitionals, 0.1 per cent., 1,400. Two normoblasts seen in counting 1,000 whites, or 2,800 per c. mm.

A study of the blood in this case is of interest from several standpoints. On the day of the first examination, May 23, it gave the typical picture of a chronic lymphatic leukemia, the tremendous increase in the small lymphocytes being the most marked feature. Most of these cells were smaller than the red cells, had almost no cytoplasm, and their nuclei stained very deeply with Wright's stain; a smaller number were about the size of a red cell, or slightly larger; they had a somewhat greater amount of cytoplasm, which was very faintly blue, and a deeply-staining nucleus, not quite so dark as the first variety. A third variety of small or intermediate lymphocytes, slightly larger than the red cells, showed a narrow rim of cytoplasm which had taken the stain more deeply than the nucleus, which was concentrically placed and stained light blue; it frequently showed a nucleus. Numerous irregular masses, stained a purplish-blue, were undoubtedly small lymphocytes of the larger varieties which were artificially broken down in making the smears, for they were not seen in the first preparations and were much less numerous in thick smears than in thin ones. The large lymphocytes were only present in very small numbers in this first preparation, and differed only in size from the last-named varieties. Polymorphonuclear neutrophiles were present only in very small numbers, being absolutely as well as relatively decreased. The red cells showed a picture of a moderate anemia of the secondary type, the cells being practically normal in appearance, though somewhat paler than normal. A very few normoblasts were found after prolonged search. On December 10 the white cells had increased in numbers enormously, 1,406,000 per c. mm., the highest white count of which Woodward has found any record in the lymphatic type. The character of the cells had changed also. The large forms of lymphocytes were much more numerous, relatively and absolutely, than in any of the previous specimens. They had, as a rule, a large nucleus rather faintly stained, with a broad surrounding mass of cytoplasm staining only slightly. The small lymphocytes were mostly of the larger types also. One large lymphocyte was seen with a double nucleus, each portion of which showed a nucleolus. Some of the larger lymphocytes were vacuolated. The red blood-count remained almost stationary throughout. Nucleated reds were very rare except in the last count, when 2 were seen in counting 1,000 white cells. The hemoglobin index was persistently minus, except during a reactionary period in September, when it was 1.26, and in the next examination, when it was 1.11. None of the rod-shaped bodies, described by Auer and Ottenberg in acute leukemia, were found in any of the lymphocytes.

24. *Site of Action of Strychnin.*—It was found by the authors that when the lower half of the spinal cord is poisoned by the transfusion method, spasms confined entirely to the lower half of the animal occur when the skin of that region is stimulated. The spasms then become spontaneous in the lower half of the animal. As the poisoning increases the spasms become general, occurring in the upper unpoisoned half when the lower half is stimulated. Spontaneous general spasms then ensue. If at this stage the spinal cord is cut at a level just between the poisoned and unpoisoned portions the spasms cease in the upper half of the animal while they continue below, indicating that the upper half is unpoisoned. An injection of strychnin subsequently into the upper part of the animal again throws it into spasms. If the poisoning be more gradual, as obtained by directly applying strychnin to the spinal cord in different regions, the symptoms of strychnin poisoning are slower to develop and stages intermediate to those just described occur, beginning with exaggerated reflexes and ending with spontaneous spasms, but always localized in the beginning to the poisoned region. Later symptoms are manifested in unpoisoned regions. In an animal in a state of complete general strychnin poisoning, occlusion of the aorta was, of course, followed by a disappearance of symptoms below the point of occlusion.

After the aorta was released, a time came when stimulating the skin above the point of occlusion was followed by general spasms (both upper and lower limbs) while stimulating similarly below the point of occlusion gave absolutely no response. When either the lumbar or the cervical region of the spinal cord is poisoned with strychnin an increase in the excitability of the poisoned area is observed when the corresponding area of the motor cortex is stimulated. The same result is obtained if the posterior roots in the poisoned area are severed. If strychnin is applied to the cervical region of the cord until that region is thoroughly poisoned so that stimulation of the skin of that region causes a general spasm, and then all of the posterior roots are severed, it is found that stimulation of the fore leg area of the cerebral cortex will cause a spasm of the fore legs but none elsewhere. The stimulus required to bring about this result is weaker than that required in the beginning to cause a mere twitch, and is also weaker than that required to cause a twitch of the hind leg on stimulation of its center in the cortex at the time the cervical region is poisoned.

25. *Control of Strychnin Poisoning.*—*On the* basis of their experimental experience it seems to Githens and Meltzer that ether anesthesia, intratracheal insufflation and intravenous infusion of Ringer's solution, offers a very effective method of treatment for strychnin poisoning in animals. They see no reason why it should not be available also in cases in human beings.

42. **A Tonsillotome Improvement.**—This is an ordinary Mathieu's tonsillotome with an *improvement consisting in two* anterior pillar hooks, or retractors, 3/8 of an inch in length, either straight *or very slightly curved*, probe-pointed, and soldered to the anterior margin of the fenestra on the side of the instrument opposite to the impalement-fork—in other words, on the side next the wall of the throat. The hooks diverge somewhat as they leave the instrument, being 4/8 of an inch apart where soldered to the tonsillotome and 5/8 of an inch apart at their probe-pointed extremities. These hooks or retractors are used in the following manner: The anterior pillar is of course, if necessary, first thoroughly separated from the tonsil, and then, the *tonsillotome having* been introduced into the throat, first the lower hook, or retractor, and then the upper, is inserted into the space between the pillar and the tonsil. The instrument is slightly drawn forward, and then the instrument is *pressed round the tonsil, and the* ablation completed in the *customary manner.*

55 *Diverticulitis of the Rectum. H. Z. Giffin, Rochester, Minn.

49. Abstracted in The Journal, Jan. 14, 1911, p. 142.

51. *Fracture of Shaft of Femur.*—*Harte suggests* finding out all that is possible about the seat of the fracture by the use of carefully prepared Roentgen-ray plates, the pictures to be taken at various angles. The operator should consider carefully what method is likely to give the best results. When the fragments are exposed, the diameter of the bone should be determined with a pair of calipers. In *no case* should the screws penetrate the opposite side. Suitable instruments, proper drills and screws, and competent *assistants* should be at hand so that the operation can be completed quickly and with as little destruction to the soft parts as possible. Before closing the wound the operator should see that it is thoroughly dry and that all dead spaces are obliterated, so that there will be no possible chance for the development of a small hematoma, which is so conducive to later infection.

52. **Fracture of the Patella.**—The point emphasized by Alexander in the operative technic is the advantage of the silver wire. Out of thirty cases that he has been able to follow, four refractured the patella; three of these were sutured with absorbable material. The one that refractured with wire was due to a fall downstairs, and so great was the strain thrown on the patella, that the wire cut through the upper fragment.

He regards silver wire as the most aseptic and at the same time the strongest suture material that can be used. The only disadvantage is that it occasionally has to be removed. Removal was necessary in three cases in this series. This undoubtedly can be avoided, provided no infection occurs, but even if skin infection—the most common in this operation—does occur, if the skin incision is well away from the line of the fracture, and if the ends of the wire are not left too long and are well covered by the tendon, fascia lata and prepatellar bursa, removal of the wire may not be necessary. If the wire has to be removed, however, it can easily be done with little inconvenience to the patient. That wire causes softening of the bone around the opening is highly improbable unless some infection occurs. Wire is certainly no more irritating than any other material used in these cases, as kangaroo tendon, chromic gut, or even, as has been used, silkworm gut.

53. **Nephro-Ureterectomy.**—Lilienthal describes a new method of operating which he devised.

55. **Diverticulitis of the Rectum.**—Giffin reports two cases in which operation was done. In one there was carcinomatous degeneration.

70. **Phenolphthalein Test.**—In his observation of the phenolphthalein test, Storck noted that whenever it gave a positive reaction, the benzidin test also proved positive. The benzidin test several times showed a positive reaction when the phenolphthalein, guaiacum and aloin tests were negative. In the experiments, from 2 to 5 c.c. of blood had been given once daily for forty-eight hours previous to the application of the test. It was found that when more than 15 c.c. of blood were ingested in forty-eight hours the phenolphthalein test always proved positive, but the guaiacum and aloin test often failed.

96. A paper based on the same observations by the same author was published in THE JOURNAL, Jan. 21, 1911, p. 198.

98. **Cultivation in Vitro of the Thyroid.**—Since Sept. 22, 1910, the authors have cultivated the thyroid gland from mammals, many times. Small fragments of the gland were extirpated from living and anesthetized dogs, cats and guinea-pigs, and cultivated in the plasma obtained from the same animal or an animal of the same species. These cultures are distinguished as autogenic and homogenic. In all, they have now made fifteen series of cultivation experiments with the gland, each of the series being composed of from four to thirty separate cultures. The proliferated elements consist of connective tissue and epithelial cells, the former predominating. The cells survive in cultures for two weeks or longer, which period can be increased by secondary and sometimes tertiary cultivations. The authors call attention to the fact that the method of growing *in vitro* organs such as the thyroid may come to be used with advantage in the study of the substances concerned with the internal secretion of certain glands.

99. **Cicatrization of Wounds in Vitro.**—The process of the healing of a wound outside the body has been observed and recorded by Ruth in five experiments. The method of study consisted of making an incision or a rectangular wound in the middle of a small fragment of skin and cultivating it outside the body in a drop of plasma. The reparation consists of three mechanisms: the sliding of the epithelium from the edges of the wound into the open space, the epidermization and the progressive contraction of the original edges of the wound.

100. **Transfusion.**—This paper offers a solution of a special problem in isoagglutination; namely, the question whether transfusion is permissible between persons whose sera agglutinate the red blood-cells of each other. It also shows why such transfusions are not regularly followed by serious symptoms. Ottenberg found that intravascular agglutination can occur, and is the probable cause of occasional untoward symptoms, or even death, following transfusion of agglutinative blood. In the majority of cases, however, it does not occur, or if it does, it causes no symptoms. This is dependent on the influence of three factors: (1) concentration of the agglutinin; (2) absorption of the agglutinin by an excess of agglutinable cells; (3) interference with agglutination by an excess of non-agglutinable cells, so that when clumps occur they are microscopic in size. If, for a given transfusion, a non-agglutinative donor, i. e., a donor whose blood is of the same agglutinative class as the patient's, cannot be obtained, then

it is safer to use a person whose serum is agglutinative toward the patient's cells than one whose cells are agglutinated by the patient's serum. Ottenberg suggests that tests for agglutination as well as for hemolysis, ought to be made before transfusion. When time does not permit this, one has to weigh the possible dangers of agglutination or hemolysis against the dangers of letting the patient go without transfusion. Agglutinable cells when transfused are taken up by the phagocytes in the patient's blood; and, for this reason, the transfusion of agglutinable blood, even when no accident happens, can be expected to do little permanent good.

134 *Pseudomembranous Croup.* T. C. Nichols, Morgan.
135 Splenic Leukemia. E. D. Sellers, Fisherville.

127. **Treatment of Dysentery.**—After castor oil has been given and the bowels thoroughly moved, Barbour says that some astringent like bismuth subnitrate may be prescribed, 10 grains every *two hours until* the stools are dark and the frequency diminished. If the stools are not discolored by the bismuth then he would give zinc sulphocarbolate in ½-grain doses every two hours. If there is no fever then small doses of Dover's powder may be given, but usually will not be found *necessary if* there has been a thorough emptying of the bowels. When there is blood in the stools, bichlorid of mercury, in 1/150-grain doses should be given every two hours until the stools show some bile, when the bismuth may be substituted. For the cramping, the tormina and tenesmus hot applications over the stomach *will give great comfort.* Hot flaxseed or a glycerinized paste will be helpful. Warm enemata will help relieve the straining, sometimes starch and laudanum eases those cases in which the rectum is very congested and apt to prolapse with the stool. Occasionally, suppositories containing *opium and* belladonna will quiet this intense activity. Or the *official liquor antisepticus* alkalinus well diluted with warm water as a *colon douche* will deplete the inflamed area. With more extensive experience Barbour has grown to use the astringents less and less, for the removal of the fermenting and putrefying mass from the bowel has nearly always stopped the diarrhea. To gain this end the following prescription has been found *very useful* by him:

℞	gm. or c.c.		
Olei ricini	8	or	ʒij
Pulveris acaciæ	q. s.		
Syrupi rhei aromatici	30		℥i
Misturæ cretæ q. s. ad	60		℥ii

M. Fiat. emulsio. Sig. One teaspoonful every two hours.

When the character of the stools show that the upper bowel has been unloaded there will be a great improvement in the condition of the child. Then the astringents may be administered with benefit but will not always be found necessary.

144 *Use of Oxygen Baths. A. Bernheim, Philadelphia.
145 *The United States Pharmacopeia. M. H. Fussell, Philadelphia.
146 The Metric System. E. H. Long, Buffalo, N. Y.

144. **Oxygen Baths.**—The use of the oxygen bath in a great variety of affections is advocated by Bernheim. He says that in addition to exercising a powerful suggestive influence, the oxygen bath exerts an effect on the innervation as shown by its removal of parasthesias, its soporific property, and its general sedative and indirectly stimulating action. It assists the circulation, deviating the blood from the skin and doubtless from the viscera, very probably to the skeletal muscles. It reduces excessive blood-pressure and the frequency of the pulse as well.

145. **United States Pharmacopeia.**—Fussell protests against the presence in the Pharmacopeia of such combinations as pulvis acetanilidi compositus. The best method of prescribing acetanilid and caffein is to give to each individual for whom these drugs are used the dose necessary for that individual, and for the particular condition present at the time the patient is seen. This cannot be done if a fixed formula is used, even though, of course, one may use different doses at different times. It is manifestly impossible for anyone to tell before a case is seen just what dose of the drug is necessary. To advise *the* use *of compound* remedies is *to confirm* slipshod, improper methods of prescribing. On this principle, fixed formulas should not be used. If it is not correct principle to use fixed formulas, then they surely should be expunged from the Pharmacopeia.

Still another point made by Fussell is the following: The Pharmacopeia to-day contains certain drugs, their preparations. the method of manufacturing them, their doses, *their* description, and in certain instances, tests *for their purity* and assay. As the book stands, therefore, it is manifestly of great use to the *pharmacist.* Its only use to the general practitioner is the knowledge it gives him of what is supposed to be useful in drugs and their doses. It gives no hint of *their indications* or contraindications, of their toxic or non-toxic properties. All this knowledge he must perforce get from *other* books, or from manufacturing chemists. He can get reliable information from the various publications on materia medica or from the dispensatories, *and he does get some from* these sources; but, sad to relate, most of the *information* as to drugs which the average physician now obtains after *graduation* is from manufacturing drug firms, in the *form of more* or less well-written literature, accompanied by samples and often supplemented by the glib-tongued detail man. Fussell has had described to him the treatment being carried *on* in certain cases, and has been able to *recognize* but *few of* the articles used, because they were prescribed under *trade* name-of which he was entirely ignorant. One reason why the drug firms, with their literature and instructed agents, are such potent powers in grounding the young physician as to the means he should use in prescribing is because that method is easy and is brought immediately to his attention, whereas the knowledge of materia medica is more or less difficult to attain. Another reason is because the medical schools are not insistent enough in teaching their students that the only proper method to pursue in prescribing drugs after they become practitioners of medicine is to hold fast to that which has been proved of value, and to accept new remedies only after their usefulness has been attested by men of standing by methods of value. Therefore, he continues, if the next issue of the Pharmacopeia is made to contain the therapeutic indications of the drugs recommended for use, it will be of some practical value to the practicing physician. If this should make the volume too bulky, two volumes might be printed; one after the style now in use, and the other to contain the names of the drugs, their description, their dose, and a short description of their therapeutic use.

150 *A Case of Masked Tertian Malarial Fever with Marked Mental and Nervous Manifestations and with Unusually Few Parasites in the Peripheral Circulation. W. E. Musgrave, Manila.
151 An Effort on the Part of the Bureau of Health to Improve the Milk Supply of Manila. C. Fox, Manila.

150. **Masked Tertian Malarial Fever.**—At the age of 14, Musgrave's patient had a moderate attack of chills and fever, which recurred at irregular periods for about one year. At the age of 21, he suffered an attack of pleurodynia, following exposure, which kept him in bed for about five days. When 25 years old, he was attacked by bronchitis, which, however, was so mild as not to confine him to bed. At 29 and 31 years of age, there were attacks of influenza, moderate in severity, confining him to bed for about one week in each case. At 35 years of age, he had diarrhea, which lasted for about two weeks and did not incapacitate him for duty. In 1897, there was an attack of intermittent fever ushered in by a chill, two other chills occurring during the first ten days. Malarial parasites were not found. Following this illness, he began to be troubled with palpitation of the heart, shortness of breath on exertion, indefinite rheumatic pains occasionally in the fingers, but no swelling or fever. About this time he began to be troubled with nervousness, inability to think on a definite subject for any length of time, insomnia, and worry over petty details. In July, 1897, he was granted sick leave for nervous debility and rapid heart action; this leave was later extended on other certificates to November. During this time, in addition to periodic attacks of intermittent fever, the general nervous condition failed to improve much and he began to be troubled with a suffocating sense of oppression in the chest and throat. At times there were spells of dizziness. In the fall of 1898, jaundice of a severe type developed and lasted for about four months. The jaundice came on gradually and was accompanied by pain and tenderness over the liver and abdomen. During the latter part of this trouble, chills and fevers developed, lasting for about three days, and a few tertian malarial parasites were found.

From about July 1 to Aug. 12, 1899, there was mild continuous fever. While on sick leave convalescing from this attack, he was exposed to the hot sun for some time and suffered with a recurrence of the old symptoms, insomnia, burning oppressive headache, palpitation of the heart, weakness, general debility and nervousness; and in addition had fever again, which lasted for a week or two, but no chills. His condition again improved and on arrival in the Philippine Islands in October, 1909, his general health was fairly good. The hard duties and the trying climate of the tropics, however, soon caused a return of the old symptoms. The mental phenomena became very marked and the patient made application to be retired on account of mental and physical debility, stating that he believed himself insane. While under observation after this application, he suffered from two attacks of fever, one of them accompanied by jaundice, but malarial parasites were not found. He was finally invalided to America with a diagnosis of melancholia and severe cerebral neurasthenia.

On returning to the United States, he was again placed under observation in one of the large hospitals. While there, he had two or three attacks of fever of an irregular type; but again malarial parasites were not found. He made a second application to be retired for mental and physical disability and the hospital authorities recommended that he be transferred to an insane asylum. Instead, however, he was transferred to the Army and Navy General Hospital, Hot Springs, Arkansas, for further observation and report. On admission, the patient complained of a constant feeling of mental and physical depression and difficulty of concentrating the mind on any one subject, especially on details. Forced thinking in one channel, as in adding a column of figures, gradually weakened the memory so that all track of count was soon lost. All exercise, whether physical or mental, was followed by mental and nervous prostration and physical exhaustion. There was insomnia, mental depression, palpitation of the heart and a suffocating sensation in the chest and throat. Practically nothing was found on physical examination. The patient was fairly nourished and developed; his color was slightly yellow; the general sensation was good; the reflexes normal; the chest negative. There was no apparent enlargement of the spleen, but slight enlargement of the liver and tenderness on deep pressure over the gall bladder. The temperature, pulse and respiration were normal. The red blood-cells numbered 4,020,000, the leukocytes, 6,280; the hemoglobin was 92 per cent. (Fleischl). The differential count showed eosin 0.8 per cent., mononuclears, 2.3 per cent., polynuclears, 75.5 per cent. and irregular cells, 2 per cent. Malarial parasites were not found in fresh or stained specimens. The urine was normal and remained so throughout the five months that he was under observation. The patient did not have diarrhea; but following the hospital custom in cases returned from the tropics, he was given a saline and the stool examined microscopically, but nothing abnormal was found.

After seven weeks in the hospital he had a slight chill one night, which he said was followed by fever and sweat. His blood was carefully examined, but no malarial parasites were found. Following this attack and continuing until the true cause of his trouble was found and removed, he complained constantly of photophobia, which at times was very marked. Seven days after the first chill he had another one at night, which was also followed by fever and sweat as well as by a slight jaundice. Again malarial parasites were carefully sought for but not found. Following this chill the mental and nervous phenomena became more marked and the patient sang, laughed and talked almost constantly for about twenty-four hours. Five days later, there was another chill and the temperature reached 104 F., with more marked jaundice and gastro-intestinal symptoms, including vomiting, slight diarrhea and abdominal pain. The abdominal pain was most marked in the region of the gall-bladder and the patient had not been free from it since the first chill. Malarial parasites were again sought for but not found, either in fresh or in stained specimens. Two days afterward there was another chill similar to the last one, and on this occasion the examination of the blood showed a few—very few—parasites. At this time the patient was in a nervous and mental condition requiring a constant attendant.

Immediately after the finding of the parasites, the patient was put on 1 gram doses of quinin every four hours until marked cinchonism was produced, after which he was kept on 3 grams of quinin daily for fifteen days, when all medication was stopped. Two weeks afterward there was another slight chill and a few parasites were again found. He was then put on a systematic quinin treatment extending over a period of five months, as follows: 3 grams in three doses daily for fifteen days; then 3 grams in three doses on alternate days for one month; then once a week for another month, and finally once every two weeks for at least two more months.

In addition to this treatment, the patient had thermal baths, and iron, arsenic and strychnin. A clearing up of the symptoms was noticed shortly after the quinin treatment was instituted and progressed rapidly. This case is reported somewhat in detail because it is believed to be rare, and because of the injury that was done the patient by a faulty diagnosis which came so near causing him to be incarcerated in an asylum.

155. Abstracted in The Journal, Feb. 25, 1911, p. 617.

156. **Spontaneous Hemorrhage.**—A review of the literature, and a study of nine cases of spontaneous hemorrhage in new-born infants, serve as the basis of this communication. Schloss and Commiskey have treated seven new-born patients with hemorrhage by subcutaneous injections of human blood. The first patient was treated in April, 1908, with, first, an injection of 20 c.c. of human blood serum, and later, an injection of whole blood. The whole blood was used instead of the serum for the reason that it was easier to obtain and could be used immediately, the time required for the serum to separate being saved. It seemed an additional advantage to inject, not only the serum, but also the formed elements which have influence on the coagulation of the blood. In most cases the blood was taken from one of the parents. The required amount was withdrawn from a vein of the forearm by means of an exploratory syringe and injected immediately into the subcutaneous tissue of the infant's back. Of the seven infants thus treated, six recovered and one died. The fatal case was in an infant who had suffered from multiple hemorrhages for eight days and died three and one-half hours after admission to the hospital. The patient was in a moribund condition when admitted and received only a single injection of 10 c.c. of blood. In five of the six cases in which recovery took place, the hemorrhage ceased soon after treatment, and at the same time there was marked improvement in the general condition. In four cases, the hemorrhage was rather severe and the patients presented all the signs of severe anemia due to loss of blood. One case was of moderate severity. In the remaining case a positive Wassermann reaction was obtained; the hemorrhage was only slightly improved after the blood injections, but ceased after the use of mercurial treatment. Whether the blood injections were of value in this case was difficult to determine. The authors believe that the best results can be expected from the use of human blood or serum. In the four successful cases the curative effect of blood transfusion was immediate, but, they say, this method of treatment must have a rather restricted field. The technical difficulties of transfusion in a young infant are formidable and render the method available only in the hands of a very skilful surgeon.

157. **Changes in the Appendix During Infancy.**—Among 200 appendices examined by Smith, fifteen showed inflammatory changes of varying intensity. The two youngest infants were 13 days and 17 days old, respectively. In nine instances, the age ranged between 20 and 30 days. Four infants were between 1 month and 2 months old. In two instances, the cecum was still in an incompletely descended position, lying between the iliac crest and the liver; but in the remainder of the cases the cecum occupied its usual position in the iliac fossa. Three times the distal part of the appendix was found hanging over the pelvic brim, and in such instances the distal part gave the evidence of severe inflammation. In eight cases, the appendix occupied a position directly behind the cecum and proximal part of the ascending colon. It is in this position of the appendix that in infants sharp angulation frequently occurs. The cause apparently is found in the relatively small retrocolic compartment at the time of birth, to which a relatively large appendix accommodates itself. Thus, the appendix passing upward directly behind the cecum and colon, may be bent sharply downward by the upper limit of the retrocolic space formed by the reflection of the peritoneum from the ascending colon to the iliac fossa or posterior parietes. Under normal conditions, even, fusion of the appendix with the cecum, ascending colon, posterior parietal peritoneum or iliac fossa is frequently found. There may result from these conditions not only a permanent fixation of the sharply bent appendix, but also changes in the form of the mesentery of the appendix, possibly causing circulatory disturbances.

In the majority of the cases reported by Smith, inflammation occurred when the appendix was found sharply bent on itself, lying in close relation with the cecum and colon; and in several instances the inflammation was more marked at the site of angulation than in other parts of the appendix. In three cases, the proximal part of the appendix passed upward, inward and to the left, so that the distal part lay curled behind the mesentery of the terminal coil of the ileum. The last described position of the appendix is that most frequently found in infants, as it formed 50 per cent. of all cases in 1,050 autopsies in infants studied by Smith. It is of interest to note that although the majority of inflammatory changes were found in appendices lying erect directly behind the cecum and colon, this variation in position of the appendix in the infant was found in only about 25 per cent. of all infants. Peritoneal exudate was present in seven cases. Thrombosis of the arteries occurred in the appendix and in the mesentery of the appendix in several instances.

168. **Can the Future Sex of the Family Be Controlled?**—Kain agrees with E. R. Dawson that the supplying ovary is in reality the essential factor in the causation of sex. Dawson held that the sex of the fetus is not due to the male parent, but depends on which ovary supplied the ovum which was fertilized, and so became that fetus. He found that a male fetus is due to the fertilization of an ovum that came from the right ovary, and a female fetus is due to the fertilization of an ovum that came from the left ovary.

169. **Medical Expert Testimony.**—Rogers suggests as a remedy for present evils that one or more experts should be jointly selected by the two opposing parties, and that these experts should be paid by both sides. In case the two sides should be unable to agree in their choice, the judge might deliver a casting vote; or each side might choose an expert, and a third might be selected by the two experts originally chosen, or by the court—these three physicians to make a joint report. He suggests further that the medical testimony in any given trial might be reviewed by a special committee appointed for that purpose by the medical council of the local medical society. By this means, a physicians who was found guilty of habitual perversion might be expelled from the society and thus discredited in the eyes of the court

2. Traumatic Myositis Ossificans.—One case of this kind is reported by Godlee. A young man had been kicked on the front of the thigh at football.. When Godlee saw him there was a very large oval swelling on the front of the lower half of the thigh. It was symmetrical and very hard, except just above the patella, where it fluctuated, and there was only slight pain on movement. There was pain and stiffness for several months. After three months the mass was slightly smaller. It was obviously fixed to the bone. After another month the lump had almost gone, but a skiagram showed that there was then a distinct flake of bone on the front of the femur, fading off above into the surface of the shaft, but ending below in a sharp spicule. Godlee points out that a very large swelling without treatment may diminish so much in size as almost to disappear and cause no further trouble or inconvenience. He raises the question whether this condition should be called myositis, and what is the evidence that it is due to inflammation of muscle. He thinks it more probable that the essential things are, first, an injury to the periosteum, and, second, an effusion of blood; and that the injury to muscle and the inclusion of muscular fibers in the callus are, so to speak, accidental, though they no doubt govern the shape and position of the new mass of bone. In other words, the injury is more analogous to what occurs when periosteum is stripped off in such operations as excision of the elbow, or in the cephalhematomata of infants, in which it is easy to demonstrate true bone at the margins of the clot, or to the formation of provisional callus in simple fractures.

3. Traumatic Myositis Ossificans.—Two cases are reported by Makins. The patients were of the same age, came under observation at the same time, and while one was treated by an active method, the other practically recovered spontaneously. Makins maintains that no active treatment should be adopted in the early stages of the condition. The frequency with which two muscles of the body, the quadriceps extensor femoris and the brachialis anticus, are affected seems to Makins to support the theory that the exciting influence is to be referred to bone-forming cells detached from the periosteum. Makins says that in the general line of treatment to be adopted a period of some weeks' complete rest should be maintained during the continuance of the active progress of ossification. When it is judged by clinical observation and Roentgen-ray examination that progress has ceased or that the process is retrogressive, massage and exercise should follow. Operative treatment should only be considered when the process has manifestly come to a definite standstill, and the patient suffers from functional disability which there is a chance of relieving.

8. Deformity of Female Generative Organs.—In the first case cited by MacEwen, a woman, aged 46 years, was suffering from symptoms pointing to intestinal obstruction. The abdomen was distended and tender to palpation, particularly over the left iliac fossa, where a large mass was easily detected on palpation, and it was dull to percussion. On vaginal examination, the cervix was found to be normal in position and direction, but small and ill-developed. The uterine sound could not be introduced into the canal, but an ordinary probe went in for about an inch. The fundus could not be detected. The vaginal roof on the left side was occupied by a mass which was tender to palpation, while on the right side a hard rounded mass was detected which projected toward the rectum, and was easily felt in rectal examination. This mass was about the size of a golf ball and was fixed. The peritoneal cavity was opened and a quantity of sanguineous fluid was evacuated. A large tumor, subsequently ascertained to be fibromyomatous, at once presented. This tumor was freely movable, being attached to a pedicle, which had become twisted and was partially gangrenous. The pedicle was ligated down close to what was supposed to be the serous surface of the uterus and the tumor removed. The left Fallopian tube was also in a gangrenous condition and was also removed. The left ovary appeared normal but of small size. On passing the finger down along a course of the rectum a mass was now detected. There was no uterine body present. On the left side there was an ill-developed broad ligament, with the gangrenous tube already mentioned, and fairly normal ovary. On the right side, the appendages seemed to be entirely wanting, while a little to the right of the normal position of the uterus the hard mass referred to presented. It emitted a slightly hollow note when tapped. It consisted of a roughly spherical shell of osseous matter, which contained an oily material at first sight resembling pus. No hairs, teeth or other tissue elements were present. The patient made an uninterrupted recovery save for slight transient jaundice for a few days after operation.

MacEwen expresses the belief that the intestinal obstruction in this case was probably due to the pressure of the fibromyoma on the bowel, but no evidence was obtained of any portion being damaged thereby. This woman had menstruated regularly. In the second case there was an absence of the lower end of the vagina.

17 *Acute Pneumonia in Children. J. P. Parkinson.

17. Acute Pneumonia in Children.—With regard to the general treatment of the disease, Parkinson says that the child should be put to bed, and frequently moved from side to side to allow collapsed areas of lung to expand, for the same reason as a fit of crying is useful now and then. The room should be well ventilated so that oxygen is given in a natural way, though oxygen from a cylinder may be useful in cardiac failure with cyanosis. Bronchitis has to be treated on the ordinary lines, and if there be much secretion an emetic may give relief. Ipecacuanha often fails to produce vomiting, and the author considers a small dose of apomorphin safe and efficacious. Ipecacuanha is much too frequently prescribed, he asserts, for it is useless when there is no bronchitis, and when there is, it is by no means sure that this drug acts favorably. It is also certain, Parkinson says, that it upsets the digestion; it is better, therefore, if the child seems to be getting rid of the bronchial secretion without drugs not to give them unless there is definite indication for their employment. The author has often found a hot mustard bath useful in cases of collapse in young infants; it relieves congestion of the lungs and heart by dilating the peripheral arterioles as well as helping the action of the skin. He insists on disinfection of the mouth and teeth to prevent further infection of the lungs. Alcohol, he says, is not necessary as a routine treatment, but may be very useful, especially in long-continued bronchopneumonias, and in cardiac failure. Brandy, well-matured, has an action far superior to that possessed by the cheaper varieties. The feeding in acute pneumonia is of the greatest importance, and so long as a child takes its food all goes well; one of the earliest signs that cause anxiety is failure of the appetite. An important rule is, more water and less food than in health. It has been found from examination of the digestive ferments in children suffering from acute disease that the peptonizing power of the stomach and pancreas is very weak. Emulsifying powers are real or absent. The greatest activity is in the diastatic power of the pancreas. The practical inference of this is that the food should consist chiefly of carbohydrates, such as starches and sugars; fats should be given in very small amounts and proteids may be predigested. If curds are passed in the stools the milk should be diluted or peptonized.

33 Structure and Development of Uterine Mucosa. E. Retterer and A. Lelièvre. Commenced in No. 2.

31. **Uterine Pregnancies After Extra-Uterine.**—Essen-Möller remarks that very little attention has been paid to pregnancies occurring in the uterus after an extra-uterine pregnancy, while a number of articles have been published on simultaneous uterine and extra-uterine pregnancies. Nilsson was able to compile sixty-eight cases of this kind in a memoir not long ago, and a number have been reported since. In Essen-Möller's experience with fifty-six patients with extra-uterine pregnancy, 46 per cent. of the thirty-nine women followed to date became pregnant again later; the sound tube performed its functions apparently normally in twenty-eight pregnancies, two of the women passing through three pregnancies afterward. Seventeen of the thirty-nine women thus bore healthy children, and this experience confirms the necessity for leaving the sound tube unmolested in operating for extra-uterine pregnancy. Engström has reported uterine pregnancies in six cases after removal of the pregnant tube and liberation of the other tube from adhesions; Prochownik has reported the same in four cases, and Essen-Möller reports a pregnancy after the release of the sound tube from adhesions, although in his case the succeeding pregnancy was likewise tubal. The main point in respect to pregnancy later seems to be the refraining from drainage. The tabulated details of his fifty-six cases show only two cases in which a pregnancy followed when there had been resort to drainage, and in these two cases the succeeding pregnancy was likewise extra-uterine or there was an interval of four years before the following conception, showing that the tube required a long time to regain its normal functional capacity. In Engström's series likewise drainage had not been attempted in nineteen of the twenty cases in which the extra-uterine pregnancy was followed by normal pregnancy later.

32. **Visual Disturbances in Pregnant Women.**—Weil and Wilhelm compare the visual disturbances liable with retention of chlorids, the dropsical form, and with retention of urea, the dry form. In the first type the visual disturbances are an amaurosis of sudden onset, which promptly subsides when elimination of the chlorids is once more under way; the ophthalmoscope shows nothing or merely a venous congestion around the papilla which disappears without leaving a trace. On the other hand, the distinguishing feature of the eye disturbances with retention of urea is the so-called albuminuric retinitis, the gravity of which is explained by the coincident uremia or azotemia. Even with severe symptoms of this kind, emptying the uterus generally causes their complete retrogression. In a typical case reported the patient was at the seventh month of her first pregnancy. She had had primary chronic nephritis as a child, and during the pregnancy the clinical picture of severe azotemia gradually developed, with apathy, anorexia, pruritus, albuminuric retinitis and convulsions, with almost total amaurosis, while the cerebrospinal fluid contained 2.67 gm. of urea. Delivery was induced and the copious diuresis which followed seemed to wash out the retained nitrogenous bodies and the patient rapidly recovered. Sudden transient amaurosis was observed in two other cases reported, evidently due to chloridemia and subsiding at once after spontaneous delivery. One of these patients had had eighteen, the other three eclamptic convulsions. Venesection was done in both cases. There were no convulsions after delivery.

41 *Perforation of Bile Ducts. (Traitement des perforations biliaires en plein péritoine au cours de la lithiase.) G. Cotte and L. Arnaud.

38. **Laryngeal Papillomas in Children.**—Broca and Roland expatiate on the fact that there is no good method of treatment for these laryngeal growths, ensuring against recurrence and leaving the voice normal; the only choice is to determine the least bad technic. If there is dyspnea and much wheezing, tracheotomy may be required; it is well to wait for a time after this as the tracheotomy may eventually lead to the shriveling of the growths. They come and go in the arbitrary and mysterious manner of warts on the skin. Removal of the growths through the mouth, under direct visual inspection, is of course the preferable method and can generally be done after the age of 4 or even a little earlier. But it usually requires more than one operation; the operations must be repeated during months or even years. Tracheotomy may finally become necessary, even then, if the growths sprout again and there is much obstruction of breathing. Exceptionally, thyrotomy or better, perhaps, thyrostomy, may be found preferable. Even after tedious treatment by these various technics, stricture of the larynx may compel laryngostomy. There is always the hope that the papillomas may shrivel spontaneously, however, as the child outgrows the tendency. They sprout as if growing from seed sown by the primary growth, and behave in the larynx much the same as in the bladder. Luys has recently reported a case in which a large papilloma was removed from the bladder, with no sign of recurrence, but a new crop of minute growths of the same kind developed around, requiring multiple cauterization. In addition to the danger of suffocation from the growth of the laryngeal papillomas, there is danger of a suddenly fatal inhibiting reflex. Frenkel has cited such a case in which a child of 6, with no history of dyspnea, suddenly suffocated on rising in the night. The prognosis of papillomas in the larynx is more serious in children than in adults as the lumen is smaller and as children are more liable to warty growths. Spontaneous expulsion and cure was observed by Bruns in three of the forty-eight cases he has compiled; over half the children died before the age of 3 and only five reached the age of 10 without operation. The spontaneous subsidence of the papillomas may explain these cures in some of the cases, and the possibility of this justifies expectant treatment for a reasonable time after tracheotomy. Warts on children's hands sometimes subside after the children have taken a little magnesia, and this treatment has been suggested for children with papillomas in the larynx, hoping thus to favor spon-

taneous retrogression or to aid the retrogression which may follow opening the trachea.

41. **Perforation of Bile Ducts in Lithiasis.**—Cotte and Arnaud give the details of seventy-six cases on record of perforation of the gall-bladder or a biliary passage into the peritoneum. The bile escaping into the peritoneum is almost inevitably septic in case of lithiasis. The main point in treatment, they say, is to drain the gall-bladder outward without delay, not attempting its removal until later if the patient seems unable to bear cholecystectomy at once. This operation is less difficult in these cases than under other conditions as the perforation occurs when the gall-bladder is distended and without adhesions to adjacent organs. If the operation follows soon after the perforation and the peritoneum is not seriously involved, he prefers to wipe it dry and strives to prevent absorption by pouring camphorated oil into the abdominal cavity, and keeping the patients in the Fowler position, that is, raising the head of the bed 18 or 20 inches. There were thirty-four recoveries and forty-two deaths among the seventy-six cases summarized from the literature, including a previously unreported case in a woman of 62. The gall-bladder was merely drained and the liver tamponed off but the temperature did not drop quite to normal, and six weeks later chills, vomiting and fever led to discovery of an abscess near the foramen of Winslow. Prompt and complete recovery followed cholecystectomy.

Semaine Médicale, Paris

March 15, XXXI, No. 11, pp. 121-132

42 *Exercise of the Ear in Treatment of Deafness. (De la gymnastique auriculaire et de son application au traitement de la surdité.) C. Fernet.

March 22, No. 12, pp. 133-144

43 *Diagnosis of Suppurating Echinococcus Disease of the Liver. (Difficultiés et ressources du diagnostic dans certains kystes hydatiques suppurés du foie.) F. Lejars.

42. **Exercise of the Ear in Treatment of Deafness.**—Fernet is not an otologist but he has experimented in his own person and has trained others to exercise the ear as a means of warding off encroaching deafness and utilizing all the auditory capacity left. Instead of using the "best" ear, he turns the defective ear whenever possible and strains to listen with this ear, listening for the ticking of a clock, etc., thus training the ear to listen better. In addition to this exercise in listening he strives to influence the ear muscles so as to favor the hearing by enlarging the meatus and promoting the circulation in the parts. For this he works the scalp around the ear forward and backward, then the outer ear in this way with the regional scalp, and then forward and back and up and down and then in a circle. The sensation of movement is felt down to the depths of the meatus. The exercises should be done gently, with frequent pauses. The best time is in the morning, before arising, for ten or fifteen minutes. Another set of exercises is to listen to a clock's ticking and then gradually draw farther and farther away from the source of the sound until it becomes inaudible, but gradually it is heard again if the ear listens very intensely. The reflex action of the listening act may influence the muscles of the ear to enhance the perception of sounds. By systematic training in this way it is possible to hear the ticking or other sounds at distances previously supposed impossible. The sensibility of the nerves and the better nourishment of the parts all contribute to the benefit derived. The entire organ of hearing functionates better when all its parts are in good vital condition, while any organ doing active work grows stronger and better all the time. In his own person the Eustachian tube leading to the partly deaf ear became permeable after these exercises, thus permitting normal ventilation of the middle ear.

43. **Suppurating Echinococcus Disease of the Liver.**—Lejars comments on the relative frequency of suppurative hydatid cysts in the liver and the available means for diagnosis. The complement-fixation test is extremely valuable in case of positive findings, but it is baffling to obtain a negative response when the operation reveals a large hydatid cyst, as in a recent case in his experience. The cyst was filled with fluid but without daughter cysts. In another case there had been liver colics for three years and a suppurating gall-stone process was surmised, as nothing pathologic could be palpated in the liver. A small subcapsular pus pocket was found and evacuated but the temperature ran up two weeks later and the fixation reaction was distinctly positive. There were chills and jaundice but deep punctures of the liver were negative. Finally he opened the lips of the wound and found in the very center of the liver a large hydatid cyst, distending the liver evenly on all sides, and prompt recovery followed its removal. The suppurating septic angiocholitis first found was evidently secondary to the deep cyst, which was also infective and suppurative. Lejars gives the details of a number of other cases in which the diagnosis was difficult. Fever and local and radiating pains are the most instructive features.

48. **Tuberculosis of the Ovaries and Tubes.**—Loiacono discusses the findings in twelve cases of tuberculosis of the adnexa in which operative treatment was applied. The first signs of the tuberculous process were noted between the ages of 20 and 37 in all but two cases in which the women were 46 and 47 respectively. There was a primary process in the lungs or bronchial glands in these as in almost all the other cases on record. Eight of the patients were sterile, another had had an abortion, one had borne one and another two children. The symptoms of the tuberculous process in the adnexa were merely disturbances in menstruation, leukorrhea and pains of varying intensity in the region of the adnexa, but there were no sweats, fever or anorexia and tubercle bacilli could not be cultivated from the uterine secretions. The left tube was the seat of the process in all twelve, the right being also affected in nine; the entire adnexa on both sides were involved in only three cases. Three of the patients died soon after the operation; the pulmonary processes were far advanced in these women. The other patients were in comparatively good health at the time of the removal of the diseased tubes, and they regained apparently complete health after the removal of the focus. Histologic study of the adnexa removed and the course of the cases confirm the fact that it is not generally necessary to remove the ovaries in such cases; the tubes are the organs involved, and they display a marked predisposition to tuberculous infection. Their removal is further justified by the necessity for preventing conception later in such women. Even when the ovaries seem slightly involved in the process, it is liable to retrogress to complete restitution after removal of the focus. He adds in conclusion that it may prove an advantage to flush out the abdominal cavity with a weak formalin solution, as is done after an operation for tuberculous peritonitis, in order to rinse out any bacilli that may have been scattered by the operation.

52. **Disturbances in Nervous System After Injection of Salvarsan.**—Géronne and Gutmann give the details of thirteen cases of this kind. The list includes a case with symptoms of irritation of the cerebral and spinal meninges, a month after injection of salvarsan three weeks after infection. Under a second injection of salvarsan all the symptoms subsided. In a

second case there were evidences of basal meningitis and double facial paralysis, coming on eight weeks after injection of salvarsan and disappearing after a second injection. The facial paralysis and psychic disturbances returned four months later but subsided permanently under injection of calomel. In the other cases there were respectively a basal meningitis with double facial paralysis and disturbance in the auditory nerves; double otitis interna with right optic neuritis and hemianopsia; facial paralysis; oculomotor paralysis; optic neuritis with signs of irritation of the meninges and left otitis interna; alternating double otitis interna; double otitis interna; otitis interna with predominant disturbance in the vestibular nerve, and otitis interna with the Menière symptom-complex. These nervous disturbances came on six or eight weeks after injection of salvarsan. The patients were all in the early stage of secondary syphilis except one with a tertiary gumma on the tongue. There were no syphilitic manifestations in any case on the skin or mucosa, but in one case these developed several weeks afterward. Géronne and Gutmann regard these manifestations as an inflammatory infiltration of nerves or meninges resulting from the action of the spirochetes or their toxins and readily influenced by treatment so that complete restitution is the rule. The manifestations have nothing in common, they assert, with symptoms of arsenic intoxication, and nothing of the kind, they say, has ever been observed in patients given salvarsan for diseases other than syphilis, malaria, chlorosis, relapsing fever, etc. They have also encountered in the last six months four syphilitics with disturbances in the auditory nerve who had been treated with mercury alone and had never taken salvarsan; two were in a late stage of syphilis and two had been infected five and six months before. One of the latter patients presented a typical otitis interna exactly as observed in his six patients who had been injected with salvarsan. In this latter group the patients had complained of headache before the drug had been given or their nervous system had been impaired by drink or age and most of them were women. At the same time the frequency of these nervous disturbances and their association with the salvarsan treatment suggest, Géronne and Gutmann remark, that the salvarsan must possess a certain affinity for these nerves. This neurotropic action is not enough to induce a degenerative inflammation in this or that predisposed nerve domain, but yet it is enough to induce some slight change in the nervous system, probably not appreciable even with the microscope, but yet enough to decide the localization of the syphilis. In short, these neuro-recurrences, they say, may be classed as traumatic syphilis. They recommend in conclusion treatment based on this assumption, that is, energetic mercurial treatment, bearing in mind that syphilitic manifestations in the nervous system have a better prognosis the earlier treatment is applied.

54. **Spontaneous Fracture with Tuberculous Hip-Joint Disease.**—Ehringhaus states that in no less than six cases of tuberculous hip-joint disease in his charge the bones in the entire leg became fragile from the trophic disturbance resulting from the tuberculous process. In each case there was spontaneous fracture and it occurred always at the same point where the spongiosa joined the more compact part of the bone, at the lower end of the shaft of the femur, just above the condyle. It is extremely important to keep watch of the bones below with tuberculous coxitis and to examine this special point repeatedly with radioscopy to detect any tendency to fracture and apply appropriate measures to prevent it.

55. **Improved Technic for Forcing Out Pleural Effusion.**—Aron commends Holmgren's technic, describea in these columns Jan. 28, 1911, page 312, but he thinks that the same results can be obtained without the necessity for two puncture holes. using merely a two-way trocar. One mouthpiece can be connected with the bulb to pump air into the pleural cavity while the other mouthpiece is connected with the receptacle into which the effusion is blown out by the air forced into the pleural cavity.

64 Congenital Angioma of Parotid Gland. P. Harrass and W. Suchier.
65 Ephemeral Traumatic Glycosuria in New-Born Infants. E. Hoeniger.

56. **Anaphylaxis.**—Friedberger recapitulates the arguments which have convinced him that immunity and anaphylaxis are merely quantitative variations of a single phenomenon. Both result from the presence of alien albumin in the organism, which has obtained access outside of the alimentary canal. With natural infection the albumin is produced by the bacteria only gradually; it is not incorporated all at once, like the amount causing anaphylaxis. He has been able to produce anaphylaxis or the symptoms of acute infection at will by administering large or small amounts of the foreign proteid. The temperature curve is particularly interesting under these various conditions, as he shows by detailed reports of his experiments.

60. **Precipitation in Acid Solutions of Salvarsan.**—Miessner is in charge of the veterinary institute at Bromberg and he applied arsenic treatment to ten cattle with foot-and-mouth disease; arsenophenylglycin was given to six and salvarsan to four, in an acid solution. The dose of the latter was only 3 gm., that is, 0.007 gm. per kilogram of weight, but all the animals showed severe symptoms at once—difficulty in breathing, foaming at the mouth—and they all died in from ten hours to two days. Ehrlich suggested that these fatalities might have been the result of a special susceptibility in foot-and-mouth disease, and another group of animals was treated with a smaller dose, 0.005 gm. per kilogram. Similar symptoms developed in these while cattle injected with an alkaline solution bore much larger doses, 0.4 gm. per kilogram, without any signs of disturbance. Microscopic examination confirmed the assumption that the intravenous injection of the acid solution had caused accumulation of the blood in the pulmonary artery into which the drug made its way after being injected into the jugular vein, the vessel becoming obstructed and arresting the arsenic which accumulated at this point. This assumption was confirmed *in vitro*, the acid solution entailing precipitation in defibrinated blood. The injurious action of the acid solution in man is due to the same cause, that is, thrombosis of the pulmonary artery and its sequels, as shown, he says, by the necropsy findings in a recent case in Hamburg in which death followed an injection of an acid solution of salvarsan. These data confirm the necessity for neutralizing the salvarsan. One gm. of salvarsan requires 4.4 c.c. of normal solution of soda to neutralize it; a heavy precipitate is thrown down which requires 6 c.c. more of the soda to dissolve it.

61. **Vaccination Against Small-Pox.**—Levy remarks that small-pox is now so rare in Germany that the present generation of physicians know scarcely anything about it and some may fail to realize the absolute importance of vaccination. He reports a case which is as convincing as a laboratory experiment in respect to the protective power of vaccination and the danger of transmission of the disease from the mildest forms. A German returning from a trip to Siberia had a slight eruption in the face but did not feel ill and paid no attention to it, but it was evidently variola. He had been vaccinated twice, the last time forty years before. His mother had never been vaccinated, and she came down with small-pox and died. Her daughter's family with three children came from a distance to the funeral; all had been vaccinated except the youngest, a boy of 2, and this child developed severe small-pox. The other members of the family contracted the small-pox from the child but in such a mild form that it was scarcely recognizable. The disease had not been recognized at

the time in any of the cases and no measures for disinfection had been applied.

67. **Continuous Drainage of Empyema of the Chest.**—Frank reports his experiences with forty-three patients with empyema in the thorax in the last ten years. About 55 per cent. of the patients were cured; in none of these cases had the empyema been installed for more than six weeks. Three boys and two girls were under 10; four boys and one girl were under 20. In only two cases was tuberculosis certain; it was suspected in two others among the twenty-four cases of recovery. His experience confirms the advantages of permanent drainage according to Bülau's technic; with this a flat flask is suspended by a strap from the opposite shoulder. The empyema drains into the flask through a rubber tube and drain inserted at the lowest point of the empyema, held in place with straps of adhesive plaster. A clamp on the tube is opened every two or three hours to allow not more than 200 c.c. of pus to escape; it is important not to drain too much at one time. He commends this technic as excellent for acute and not too old empyema; it is the simplest and the least annoying of all, he states, and the final outcome is good. Thoracocentesis should be reserved for small encapsulated empyema while the thoracoplastic operations should be reserved for the cases in which the Bülau technic is impracticable or in which there are chronic pathologic changes in the pleura.

69. **Salvarsan in Syphilis.**—Rissom concludes from his experience in the army that salvarsan should not be recommended for the sole treatment of syphilis among soldiers, although in the malignant form and with recent primary lesions it is certainly efficient. If it is used in military hospitals he advises intravenous injection of from 0.4 to 0.5 gm. followed at once by a course of mercurial treatment. The local infiltration with subcutaneous injection interferes with the military service, so that this technic is not advisable.

74. **Acute Intestinal Stenosis.**—Schnitzler advocates prompt relief of peritonitic stenosis of the intestine by opening into the bowel. He has made a fistula of this kind in peritonitic ileus in almost one hundred cases and he has never had occasion to regret it. More than once he has regretted that he had not done it twenty-four hours sooner. Feculent vomiting should not be waited for; colic pains, lack of stool and flatus and the metallic tinkling sounds in the intestine to which Wilms recently called attention—these are signs enough of stenosis and there should be no further delay. He treats the patients in this category the same as for incarcerated hernia, except that he does not try to remove the obstruction but merely makes one or more openings into the distended loops. It is foolish, he declares, to waste time and to annoy the patients with medical measures in these cases; in fact, high enemas are rarely indicated and the most misused measure in modern medicine. Only with volvulus of the sigmoid flexure is the high irrigation superior to an ordinary enema. If a small enema does not bring stool within twenty-four or forty-eight hours he advocates enterostomy without delay. When it is done early, the fistula can be made by the Witzel technic. When the ileus was not due to a neoplasm or other permanent obstruction, stool was voided by the natural route within a few days in every case. He adds that appendicitis may from the start present merely the picture of purely mechanical ileus. In conclusion, he refers to the mesenteric occlusion from compression of the duodenum by the root of the mesentery—the postoperative ileus to which he called attention in 1895. He still maintains that the dilatation of the stomach in these cases is secondary to this compression, this assumption being sustained by the benefit from turning the patient on the abdomen. In all cases of postoperative ileus he urges the physician to refrain from exploring the abdomen, mere enterostomy generally proving sufficient for the time being.

76. **Salvarsan in Syphilis.**—Port insists on having his patients sign a paper which states that the new drug has not crowded out the tried and tested mercury, but is administered at the special desire of the patient and with the understanding that a course of mercurial treatment must follow and that the hospital is not to be held responsible for any injurious consequence of the salvarsan injection. He states that he was delighted to have the certificate in his hands in the numerous cases in which a deep necrotic process developed at the point of the subcutaneous injection. This occurred, he says, in a shockingly large proportion of his sixty cases until he changed to the intravenous technic. In one case there was evidently a small infarct in the lung responsible for pain in the left chest, area of dulness and bloody sputum the day after the injection. The danger of thrombosis and embolism is shown by this case not to be so negligible as many maintain. In any event, the patient should stay in bed for two or three days after the injection. One of his patients insisted on leaving the clinic twenty-four hours after the intravenous injection, but returned two days later with local thrombosis, the arm being swollen; the symptoms subsided under appropriate measures in a few days. On account of the danger of such disturbances the injection is made in the left arm. It is his impression that patients with recent infection react with higher temperature than others. Vomiting and diarrhea were common after intravenous injections, and one patient became very deaf but hearing gradually returned in the course of two weeks. One patient had total right deafness coming on five months after subcutaneous injection of the neutral emulsion, although there were no signs of recurrence of the syphilis. He thinks that these cases of neuro-recurrence are due to toxic injury of the nerves, not only by the endotoxin of the germs killed by the salvarsan but by the drug itself, and he thinks that patients should be warned against such eventualities. He declares, further, that the intravenous technic is *not* suited for general practice, and that it is *not* free from danger of thrombosis and embolism even in the hands of specialists.

84 *Co[illegible] Spasm with Hour-Glass Stomach. (Ueber Erfolge und Aussichten einer konservativen Therapie des Sanduhrmagens, nebst Beiträgen zur röntgenologischen Diagnostik desselben.) E. Schlesinger and J. Nathanblut.

81. **Tumors in Cerebellopontine Angle.**—Leischner analyzes ten cases of this kind in which operative treatment was applied in the surgical clinic at Vienna in charge of von Eiselsberg. The patients were between the ages of 30 and 50, and the symptoms pointed unerringly to a process obstructing the cerebellopontine angle. In one case, the history of syphilis, the positive Wassermann reaction and the transient benefit under antisyphilitic medication suggested the possibility of a gumma, but the rapid disturbance in vision compelled immediate operation, which proved to have been fully justified as the growth was a true fibroma. Headache, dizziness and deafness in one ear or subjective sounds in the ear first brought the patients

to the clinic; then came vomiting and choked disc. The operation was done in two sittings with an interval of from six to nine days. The intervention has been borne much better since it has been the practice to maintain permanent subcutaneous saline infusion during the first sitting. No attempt is made to drain the site of the tumor since one patient succumbed to secondary infection from this cause. Six of the patients died; four were discharged much improved. This brings to fifty-one the number on record of tumors of this kind given operative treatment. Excluding the incomplete operations, twenty-nine of the remaining forty-four patients died during or soon after the operation, including six who did not survive the first sitting. Shock or paralysis of the respiration or heart centers was the fatal factor in most of the cases; fulminating hemorrhage as the tumor was being shelled out was the cause in three cases. Fifteen patients bore the operation well and eleven are still in comparative health from one to eighteen months since the operation. The end-result depends, naturally, on the degree to which the nerves in the region have been injured by the tumor before its removal, especially the optic nerve. The younger the patient and the smaller the tumor, the better the outcome. An operation should be advocated in every case, he affirms, in which the general condition is still good and the medulla oblongata does not show signs of injury. The tumors are generally readily shelled out, even when they have attained quite a large size.

82. **Functioning of the Stomach After Gastro-Enterostomy.**—Schüller has examined forty patients to determine present conditions after a gastro-enterostomy, and here analyzes the findings in twenty-five, including thirteen cases in which the pylorus was resected. The findings teach the necessity for making the opening at the lowest point of the stomach after resection, and further that the gastric digestion nearly always suffers after a gastro-enterostomy. The conditions in regard to the passage of fluids along into the intestine differ in the human and the dog stomach after this operation.

84. **Treatment of Hour-Glass Stomach.**—Schlesinger and Nathanblut conclude from their analysis of two cases of hour-glass stomach that Roentgen-ray examination is indispensable for estimation of the conditions, and that a superposed spasmodic contraction may be relieved by medical measures and thus the whole clinical picture be so improved that operative treatment may be avoided.

85. **Eventration for Roentgen-Ray Treatment of Internal Organs.**—Werner and Caan have been applying the method suggested by Carl Beck for temporary eventration of inoperable cancers to submit them to the action of the Roentgen rays. They report their experiences with fourteen cases including nine with inoperable gastric cancer, two with advanced rectal carcinoma, and one each of a gall-bladder, ovarian or colon tumor. Besides the beneficial action of the radiotherapy, it is possible, by this means, to apply more radical local measures to the growth. They describe the technic with which they eventrated gastric and rectal cancers, keeping them exposed in this way for some time while the region around is fully protected. They think this method of temporary eventration should take the place of simple exploratory laparotomies and of gastro-enterostomies in most cases, and of other palliative measures. Five illustrations show the technic advocated for this "radiosurgery," as they call it.

89. **Roentgen Rays in Diagnosis of Pregnancy.**—Edling has found it possible to obtain instructive radiographs of the fetus as early as the beginning of the third month of pregnancy. Multiple gestation and abnormal positions and malformations can also be readily recognized by this means. He has been applying the Roentgen rays systematically to a number of pregnant women in the Malmö and Lund Hospitals, and has found the radiographs equally reliable for diagnosis of extra-uterine pregnancies. No harm from the procedure was ever detected.

101. **Disturbances in the Auditory Nerve with Acquired Syphilis.**—Mayer has been analyzing the histories of sixty-five cases of syphilitic affections of the auditory nerve observed at Graz since 1896, continuing the series of sixty-six previous cases reported at that date by Habermann. These series show that the auditory nerve is liable to become affected early after syphilitic infection, even as early as three weeks after the primary sore, and thus by the sixth week after infection. The auditory affection is most frequent during the first six months but it may not develop until after twenty-five or thirty years. Syphilitic affections of the auditory nerve generally commenced with subjective sounds in the ears and, in about half the cases, with dizziness. These symptoms were noted sometimes as part of the prodromal picture. In the later stages of secondary syphilis the ear affection usually develops accompanying recurring manifestations, in which case it may be regarded as part of the latter. The syphilitic affection of the auditory nerve almost always came on gradually and was more or less severe. It was generally bilateral or the deafness was more pronounced on one side than the other. In about half the cases vestibular symptoms were also observed, sometimes merely slight dizziness, in others severe vertigo accompanied by vomiting and serious disturbance in balance. An isolated affection of the vestibular nerve was never encountered in any of the 131 cases in the series, while this was the trouble in Urbantschitsch's five cases of disturbances in the auditory nerve after injection of salvarsan. Isolated disturbance in the vestibular nerve is extremely rare; Mayer knows of only two cases of the kind on record: Ruttin's case, in which no explanation for the disturbance was found, and Leidler's case in which the isolated affection of the vestibular nerve was traced to sausage poisoning. Ehrlich has reported vestibular symptoms in mice treated with arsacetin. These experiences show that the vestibular nerve may be injured by poisons which do not affect the cochlear nerve, and they sustain the assumption that the isolated vestibular disturbance observed after salvarsan may be the result of toxic action from this drug. The fact that not a single instance of an isolated vestibular affection was observed in the sixty-five cases of Mayer's series of syphilitic disturbances of the auditory nerve certainly sustains this assumption. Another argument in favor of it is the fact that the vestibular disturbances developed so soon, within a few hours of the injection of salvarsan, and, further, that such a comparatively large number of cases have been observed within such a short period. In conclusion Mayer reiterates that true syphilitic disturbances in the auditory nerve are not so infrequent as some have asserted recently, while, on the other hand, they differ in many respects from those which have been observed after injection of salvarsan.

102. **Disturbances in the Auditory Nerve with Acquired Syphilis.**—Frey reviews the literature on this subject citing thirty-five authors and adding that auditory affections for which syphilis is responsible are probably more common than is generally recognized as attention has not been attracted particularly to them until recently and only the more striking cases have been reported.

108. This is a denunciatory reply to Roth's article summarized in these columns, March 25, page 935.

109. **Etiology of Eclampsia.**—Dienst ascribes eclampsia to the injury resulting from accumulation of fibrin ferment from destruction of polynuclear leukocytes used up in the pregnancy. The fibrin ferment or thrombin accumulates in the liver, and in consequence of the congestion in this organ and the mechanical hindrance to the circulation in the vena cava from the pressure of the large uterus at term, the fibrin ferment does not get into the blood as under other conditions and thus does not come in contact with the antithrombin. The liver suffers from this accumulation and is no longer able to produce the necessary antithrombin in sufficient amounts. Then the fibrin ferment accumulated in the lower part of the body in such large amounts is suddenly mobilized when labor commences, and the blood is thus suddenly overwhelmed with a flood of it. This explanation of the *origin* of eclampsia has been sustained, he asserts, by his experimental research.

115 Pathogenesis of Rigidity of Abdominal Walls. (Sulla patogenesi della tensione addominale.) U. Fabris.

113. **Contracted Pelvis in Italy.**—Rigamonti states that the custom of carrying a basket on the back, the *gerla*, in common use in the Italian mountains, has a tendency to deform the pelvis, reducing particularly the anteroposterior diameter. He found contracted pelvis in 52 of the 399 women he has delivered in the last three years in his practice in an Italian mountain district with a population of 3.500. Every one of the women with contracted pelvis had been accustomed to carry heavy burdens on her shoulders in this way from the age of about 11.

120 Major Operations Under Primary Ether Anesthesia.- (L'ebbrezza eterea alla Sudeck specie in operazioni di lunga durata.) G. Gheza.

116. **Postdiphtheritic Paralysis of the Velum.**—Fumarola reports five cases of paralysis of the velum following diphtheria in which he applied Larat's technic for electric treatment. In the first three cases the paralysis dated from twenty and forty days and rapid relief followed three or four sittings, with a complete cure after eight and eleven. No benefit was anticipated in the fourth case as the paralysis was of seventeen years' standing, and none was realized. In the fifth case, the electric treatment was commenced too soon, while the diphtheritic neuritis was still in progress, the sixth day after the first signs of trouble. The consequence was an aggravation of both subjective and objective symptoms; this case teaches the importance of waiting for the subsidence of the neuritis before commencing treatment. The current may be a rapid intermittent faradic or the alternating sinusoidal. It should be turned on for about fifteen minutes. The patient should feel it but not enough to cause pain. One of the large electrodes is placed at the back of the neck and the current is closed by placing the hands or feet in a basin of water.

129 Fatal Ether Accident. (Et Dødsfald ved Aeternarkose.) J. Sturup.

121. **Hasty Eating in Origin of Stomach Disease.**—Hallas found in examination of thirty-two idiots signs of abnormal stomach functioning in no less than twenty-two. All the patients were inmates of the asylum and none chewed food properly. Akesson has also reported six patients with achylia in thirteen imbeciles examined who swallowed their food hastily, while there were signs of abnormal gastric functioning only in five of nineteen who ate more hygienically. Hallas thinks that the insane asylums offer facilities for study of gastric affections better than can be obtained elsewhere, as the patients are under observation for long periods.

123. **Non-Surgical Treatment of Cancer.**—Rovsing's article was read to open the discussion on this subject at the recent international cancer conference at Paris. He has had wide experience with various non-operative means of treating cancer, the results being negative with trypsin in his fifteen cases; fulgurization he has never tried as it cannot be thoroughly curative, while it is too painful for a palliative measure. His experience has been more favorable with Roentgen-ray treatment, especially in a number of cases of small rodent ulcers of the face. He has become convinced that the Roentgen rays actually promote the growth of carcinomas. On the other hand, they have a curative influence on some sarcomas. It is impossible to say, however, which sarcomas are going to yield to this influence; the action is local, having no effect on metastases elsewhere. At the same time he reports the complete subsidence of a sarcoma in the neck in two cases and of an osteosarcoma in three under Roentgen-ray treatment, but only one patient is still in good health to date. The details of this cured case are given with illustrations. This case seems to show that the sarcoma first must be opened up so that it can be directly exposed to the action of the rays. The sarcoma in this case was on the top of the head and after twenty-one exposures in seven weeks not a trace of it was left. The scalp flap was then replaced and five series of exposures were made later. There has been

no sign of recurrence during the four and a half years since. Rovsing thinks that radium may be counted on for a similar curative local action for cancer but, like the Roentgen rays, there is no general action. He also reports retrogression of a cancer after inoculation of erysipelas streptococci. The resulting erysipelas had an unmistakable curative action on the sarcoma on the forearm but the patient succumbed to unsuspected metastasis in the lungs. He adds that the success of salvarsan in syphilis suggests the possibility of an effectual arsenic treatment of cancer. His experiences were still more promising, he states, with vaccination according to Wright's technic. He has applied this since May, 1909, in seven cases of sarcoma, seven of carcinoma of the breast, one of cancer of the bladder, one of the vulva and one of epithelioma of the cheek. No permanent benefit was apparent in the carcinoma cases, but with sarcoma the outlook is more promising; he has two patients who seem to have been permanently cured by this means, one of a recurring sarcoma in the liver and the other in the thigh. There has been no sign of further trouble during the five and nine months since. He is inclined to accept the possibility of direct contagion of cancer. In his own family an uncle, 70 years old, had an ulcerating osteosarcoma. His young daughter tended him and soon developed universal sarcomatosis, fatal in two months. He knows of other cases in which daughters who tended a mother with cancer of the breast also developed cancer. He cites further statistics showing that in the Sorø district cancer is extremely prevalent, while scarcely any cases are known in the Aalborg district. He knows of houses where the people moving in get cancer; in one house at Faxe occupied by several physicians in turn they developed sarcoma and died in the course of a year or two—these experiences speak against the assumption of embryonal factors and point to infection. They are only clinical observations, he adds, but he is convinced that the microbe will some day be found which will explain them. In the discussion of Rovsing's article, Poulsen stated that he has kept records of 400 cancer patients after radical treatment, and nearly all have succumbed since to cancer, if not to metastasis, to a primary cancer at some other point. He even ventures to say that when a human being is once operated on for cancer, he will, if he lives long enough, certainly die of cancer.

134 *Chondrotomy for Apical Disease. (Om den operative Behandling af Spidseftise og Emfysem—Freund's Operation.) E. Brandorff.

134. **Chondrotomy for Apical Disease.**—Brandorff reviews the articles that have been published on Freund's operation to restore elasticity to the upper part of the chest wall. He has found forty-five cases on record, to which he adds four done in Denmark. The results have been very encouraging. When the operation is done on one side at a time, it seems comparatively free from danger.

Correction: Louse, Not Flea, Transmitter of Typhus.—Prof. Russell M. Wilder, Chicago, calls attention to the fact that in The Journal, April 8, p. 1073, in the abstract of an article by Nicolle in the *Annales de l'Institut Pasteur*, the word flea is used in place of louse. Mr. Wilder says that Nicolle's work has all been with the body louse, *Pediculus vestimenti*, and it is with this insect that he obtains transmission of typhus to monkeys, *not* with the flea. Mr. Wilder is correct. Nicolle states expressly that his experiments with fleas and bedbugs were constantly negative. The prophylaxis of typhus is much easier with the body louse than with the flea, as soap and water and clean linen, Nicolle says, will usually banish lice, whereas fleas are harder to get rid of.

PRACTICAL EXPERIENCES WITH BERIBERI AND UNPOLISHED RICE IN THE PHILIPPINES *

VICTOR G. HEISER, M.D.
Director of Health and Chief Quarantine Officer for the Philippine Islands; Passed Assistant Surgeon, P. H. and M.-H. S.; Professor of Hygiene, College of Physicians and Surgeons, University of the Philippines
MANILA, P. I.

The advances made during the past year in placing the etiology of beriberi on a scientific basis have now proceeded far enough to warrant the inference that prophylactic medicine has the knowledge at its command to place this scourge among the preventable diseases.

While it has been possible to control outbreaks of beriberi in public institutions in the Philippines during the past ten years by reducing the rice in the diet and replacing it with meat, vegetables, mangoes, etc., yet it was not until the 1910 meeting of the Far Eastern Association of Tropical Medicine that a rational method for the prevention and cure of the disease became available. This was due to the papers on this subject read at the meeting, especially those presented by Foster and by Aron.

Briefly, it will be remembered that these authors showed by experimental data that beriberi in man and polyneuritis in fowls could be caused by using, as the staple article of diet, rice from which the outer portion or pericarp had been removed; and that, unless advanced degeneration of the nerves had occurred an immediate amelioration of the symptoms took place when rice with the pericarp, or its equivalent, was substituted.

Numerous analyses of rice sold in the Manila market have been made by Dr. Aron, and these showed that Saigon rice Number 2, and locally polished rice almost invariably contained less than 0.4 per cent. of phosphorus pentoxid. (It is desired here to digress for a moment for the purpose of stating that the amount of phosphorus in rice is given only because it is a ready method for determining the degree of polishing that a given rice has undergone; in other words, it is a laboratory method of ascertaining whether much or little of the pericarp has been removed and at this time it cannot be said that the lack of it causes beriberi.) Unpolished or slightly polished rice was found to contain from 0.5 to 0.75 per cent. of phosphorus pentoxid.

Since the opening of the Culion Leper Colony in 1906, rice has been the staple article of diet, and it was customary to use either Saigon rice Number 2, or local polished rice. Beriberi was more or less continuously present until February, 1910. By substituting meat and mangoes for rice it was always possible to reduce the number of beriberi cases, but the disease was never completely eradicated. It was found later that this failure was probably due to the fact that many of the lepers preferred to deny themselves food rather than eat mangoes, so that the authorities had starvation as well as improper diet to deal with.

The total number of deaths at Culion by months from February, 1909, to February, 1910, among an average population of 1,537, was as follows: February, thirty-nine; March, fifty-four; April, fifty-two; May, forty-seven; June, forty-eight; July, fifty-seven; August, sixty-one; September, sixty-five; October, forty-three; November, eighty; December, 188; January, 164; or a total of 898: of this number a total of 309 were due to beriberi.

In February, 1910, the use of unpolished rice was made compulsory for all inmates of the Culion Leper Colony.

The total number of deaths by months from February, 1910, to February, 1911, among an average population of 1,952, or a 27 per cent. greater population, was as follows: February, sixty-six; March, thirty-six; April, twenty-nine; May, twenty-two; June, twenty-seven; July, fifteen; August, twenty-four; September, twelve; October, thirteen; November, fifteen; December, fifty-eight; January, fifty-two; or a total of 369, a reduction in the deaths of over one-half.

Of this number there were no deaths from beriberi after February, 1910. The increased death-rate in December and January was due to an acute outbreak of bacillary dysentery, or even a better showing would have resulted.

At the end of January, 1910, there were approximately fifty patients with beriberi undergoing treatment in the Culion Hospital. On the suggestion of Dr. Aron, 15 grams of rice polishings mixed with milk and sugar were given to these patients twice daily. Two patients in very advanced stages of the disease died within a few days after this treatment was begun; all the others began to improve. Within two weeks half of the number were able to leave the hospital, and within four weeks every patient with beriberi was reported as cured by the attending physicians of the hospital. So much for Culion.

Prior to May, 1910, beriberi was very common throughout the Philippines—in jails, lighthouse stations, charitable institutions, on Government vessels, and among the Filipino troops of the U. S. Army. An investigation has shown that it was the invariable practice to use polished rice as the staple article of diet in all of the places mentioned. In May, 1910, an executive order was issued by the Governor-General of the Philippine Islands prohibiting the use of polished rice

---

* Read at the eighth annual meeting of the Philippine Islands Medical Association, Manila, P. I., Feb. 23, 1911.

in all public civil institutions. Since August, 1910, only two cases of beriberi in the above places have come to my attention. One of these was among the crew of the steamer *Rizal*. An inspection of the ship's stores showed that the crew's rice was of the white polished variety. Further inquiry elicited the fact that it was customary for most of the crew of this vessel to use a varied diet, which may account for the fact that there were not more cases. The other case occurred in a prisoner in the Tacloban jail. The physician in charge reported that it had not been possible to purchase unpolished rice at Tacloban and for that reason polished rice was being used. He added, however, that every effort was being made to comply with the spirit of the executive order by using more meat, mangoes, potatoes, green vegetables and fish.

At the Hospicio San José, which is an insane hospital, orphan asylum and asylum for the aged, of over 700 inmates, beriberi had been constantly present at least during the past ten years. Since June, 1910, unpolished rice has been used and a few weeks afterward beriberi disappeared, and since then no further cases have been reported.

Extensive inquiry made throughout the Philippine Islands has almost invariably shown that in districts in which hand pounded or, in other words, unpolished rice is commonly used, there is little if any beriberi; whereas in districts in which machine or polished rice is used as the staple article of diet, beriberi is common. An apparent exception to this general rule is found, however, among the residents of the Batanes Islands. It may be mentioned that these are isolated islands north of Luzon and south of Formosa which have communication with the outer world only a few times each year, and owing to their inaccessibility they generally escape visitations of cholera and many other dangerous communicable diseases.

The Batanes are poorly adapted to rice culture, and for this reason considerable polished rice is imported each year, and it would seem reasonable to infer that if the present theories with regard to the etiology of beriberi are correct cases of this disease should be encountered. An investigation of the dietary of the inhabitants of these islands shows, however, that meat and potatoes are more commonly used than in other parts of the Philippines. In brief, food of various kinds, other than rice, is so plentiful that rice is not the staple article of diet to the same extent as it is elsewhere in the archipelago.

Considerable difficulty has been encountered and much opposition has resulted from the attempt to introduce unpolished rice on a large scale in the Philippines. When the Army and the insular government entered the market to purchase large quantities of unpolished rice it developed that the dealers were unable to supply the demand, because managers of rice mills refused to adjust their process of manufacture to meet the new requirements. This resulted in large quantities of rice being used that came from the mills immediately after it was husked.

The machines that are used locally for this purpose let many of the smaller rice grains pass through without the husks being removed from them. Previously such rice went directly to the polishing machine which not only polished the rice, but removed the husks from such grains as still retained them, so that the finished product was clean. It was apparent then that much of the unpolished rice that was issued in the beginning was not very clean and contained many husks This gave rise to much complaint among those who were required to use it. It was frequently alleged that the husks tickled the throats and often caused gastritis. On investigation, no reliable evidence as to the gastritis could be obtained. Commissary officers, prison wardens, and others who were directly charged with carrying out the orders to use unpolished rice, were constantly besieged with complaints and it was but natural that they should take the course of least resistance and recommend that its use be discontinued. To add to the difficulties of those who were insisting on the use of unpolished rice, the rumor spread that unpolished rice when stored in bulk soon spoiled, thus causing great financial loss. Investigation of this matter showed that there was no reason to believe that unpolished rice, when stored under the same conditions as polished rice, spoiled more quickly.

A campaign of education was then begun. Dr. Aron frequently went to the rice mills in person and was invariably able to demonstrate that rice could be rendered clean and free from husks without polishing it to a degree that would be harmful. Similar work, with like results, was accomplished by Highet in Siam, so that it may now be said that clean, unpolished rice, satisfactory in appearance, can be obtained in the Philippines and abroad, and that the original objections to its use no longer exist.

By January, 1911, so much evidence had accumulated that unpolished rice was an important factor in the prevention of beriberi that it was deemed most desirable to bring about its general use in the Philippines, for a few years at least, in order to test the theory thoroughly. At the most, no harm can result, and on the other hand there is every promise that many hundreds of lives may be saved and a still greater morbidity avoided. Experimental investigations made by Dr. Aron showed that a rice which has only been polished to a point where it still contains 0.4 per cent. of phosphorus pentoxid may be regarded as incapable of producing beriberi. Almost coincidently, similar conclusions were announced by Highet.

For purposes of convenience, then, a rice that contains less than 0.4 per cent. of phosphorus pentoxid is regarded as polished rice, and that which contains a greater percentage of phosphorus pentoxid is regarded as unpolished rice.

Accordingly, a bill was drafted which had for its purpose the bringing about of the general use of unpolished rice in those places where rice was the staple article of diet. After considerable discussion with physicians, lawyers, legislators and others, it was deemed advisable to attempt this with a law that would impose a tax of 5 centavos (2½ cents U. S. currency) per kilo on all polished rice sold, whether foreign or domestic.

Owing to the fact, however, that the legislature adjourned during the early days of February, there was not sufficient time to present this matter to both of its branches.

On account of the successful experience with unpolished rice in the prophylaxis of beriberi in the Philippines during the year, and since these data confirm the work of Fraser, Stanton, Aron, Kilbourne, de Haan and Highet, as reported at the last annual meeting of the Far Eastern Association of Tropical Medicine, it is believed that the time has come for the medical profession to aid in completing the last step in the test which promises to place another weapon in the hands of prophylactic medicine for the eradication of another of the world's serious and costly diseases.

THE RELATION OF PREMENSTRUAL FEVER TO PULMONARY TUBERCULOSIS:

A STUDY OF ONE HUNDRED CASES [*]

LEO KESSEL, M.D.
NEW YORK

In 1861 Fiedler[1] drew attention to definite rises in temperature occurring with anomalies in menstruation, particularly dysmenorrhea. He noticed that fever occurred one or more days preceding the menstrual period and disappeared rapidly with the onset of the menses. He called this "menstrual fever" and thought that it was due to an anomaly in menstruation, but not to an inflammatory process. At times since, physiologists have studied the changes occurring in the circulation, temperature and metabolism associated with menstruation; gynecologists have seen an increase in inflammatory pelvic conditions, or a lighting up of those which had been seemingly latent at this time, and finally, internists have noted the influence of menstruation on pulmonary tuberculosis, particularly the aggravation of subjective symptoms and an increase in the physical signs and temperature changes (F. Neuman[2]). Macht[3] has recently published a review and a careful study of the history of the subject and has indicated the relation between menstruation and tuberculosis, from the point of view of physiology and internal medicine. He states that the heat-regulating apparatus in woman seems to be peculiarly unstable at the time of menstruation; that those who have studied the temperature charts of tuberculous patients at this time have been impressed by the constancy and regularity of these periodic menstrual exacerbations in temperature which seem to differ only as to the frequency of occurrence. The difference in figures, he believes, is due to carelessness in temperature observations, and to disregard of relative rises in temperature; he quotes Mantoux,[4] to the effect that fever may exist without hyperthermia. Macht studied forty cases and states that 50 per cent. showed periodic monthly exacerbations. The cases are not given in any detail whatever and some of the patients were, furthermore, being treated with tuberculin at the time of observation. He finds that rises in temperature may occur in early, as well as in advanced cases, and in the former, are of diagnostic importance. In an extended experience with tuberculosis patients, I was quite unable to substantiate the observations made by Macht, or indeed those of any of the other observers, including Riebold. I consider it of interest, therefore, to add the facts gathered from our patients to indicate the variant findings. Before turning to the cases to be reported a review of the literature directly related to this phase of the subject may be of interest.

In 1899 Turban[5] described a temperature curve with a rise preceding the menstrual period by three to five days and a depression following it. Nine years later he (Turban[6]) presented curves showing premenstrual, intermenstrual, menstrual and postmenstrual temperature rises. The first mentioned he considered diagnostically the most important. Without giving the criteria for his observations he mentions that seventy-three of 100 tuberculous women showed this premenstrual fever on several occasions. Following Turban, Saugman,[7] Sabourin,[8] Kraus,[9] and Jessen[10] laid stress on the fact that premenstrual fever lent evidence to the existence of pulmonary tuberculosis.

Riebold[11] made careful studies of the periodicity of menstruation, the relation[12] between menstruation and ovulation and their influence[13] [14] on disease. He believes that menstruation is dependent on ovulation, and usually follows this by one, two, or three days; that ovulation, not menstruation, is the process which is strongly periodical and that the periodicity in woman's life processes is dependent on it. The question whether this characteristic periodicity is inherent in the actively functionating ovary, or whether external, special cosmic influences play a rôle, he thinks must remain for the present unanswered. He advances the theory that during ovulation certain secretions reach the circulation and that these cause an increase in nervous and psychic irritability, increase in blood-pressure and vital energies, general heightening of metabolic processes, and an accompanying vigorous hyperemia of internal organs and activity of lymph-flow. During such a period of increased physiologic activity, the opportunity is offered for resorption from old infectious foci, for the lighting up of latent processes, or for an increase in activity of acute infections already present, which thus become the cause of premenstrual fever. He has later shown from a study of a large series of cases, that premenstrual rises in temperature occur in a great variety of diseases, such as acute infectious diseases, anginas, gynecologic and neurologic conditions.

I have for some time been impressed by the absence of this so-called premenstrual fever in cases of definite pulmonary tuberculosis. The mention in the literature of its frequent occurrence and the emphasis placed on its diagnostic significance led to the study of the following 100 cases. These cases were observed at Bedford, N. Y., in a sanitarium, in which the hygienic conditions were especially favorable. The sanitarium is devoted to the treatment of tuberculous patients only. The patients were under constant observation; a few were confined to bed, but the majority were up and about. Of these 100 cases forty-seven were incipient, thirty-nine moderately advanced, fourteen far advanced, classified according to National Association classification.[15]

[15] Classification adopted by National Association for Prevention and Study of Tuberculosis: *Incipient:* Slight initial lesion in the form of infiltration limited to apices or a small part of one lobe. No tuberculous complications. Slight or no constitutional symptoms. *Slight or no elevation of temperature* or acceleration of pulse at any time during the twenty-four hours, especially after rest. Expectoration usually small in amount or absent. Tubercle bacilli may be present or absent. *Moderately advanced:* No marked impairment of function either local or constitutional. Localized consolidation moderate in extent, with little or no evidence of destruction of tissue or disseminated fibroid deposits. No serious complications. *Far-advanced:* Marked impairment of function, local and constitutional. Localized consolidation intense; or disseminated areas of softening; or serious complications.

The average period of observation was nine months. Rectal temperatures were taken in all but one case. The sputum in ninety-two of these 100 cases contained tubercle bacilli; of the 8 remaining patients, the evidence for pulmonary tuberculosis was:

Case 1.—Patient aged 13. Six members of immediate family and one cousin had tuberculosis. Physical examination showed bilateral apical dulness and diminished breathing, more marked on left side. Intracutaneous and von Pirquet reactions were positive. No expectoration; laryngeal smear negative.

Case 2.—Patient aged 38. Non-tuberculous family history. A history of five years of weakness and cough; five months before admission, blood tinged sputum; slight dulness and shrinkage at right apex; diminished expansion at right base; ophthalmic, von Pirquet and intracutaneous reactions positive.

Case 3.—Patient aged 18. Non-tuberculous family history; gradually increasing weakness for one and one-half years; cough; thoracic pain; lowering of right shoulder; dulness, increased voice and increased muscular resistance at right apex. Reaction to 7 mg. of Koch's old tuberculin to 102 F.

Case 4.—Patient aged 16. Non-tuberculous history; hemoptysis on two occasions; dulness, diminished expansion and crackling râles at right base; intracutaneous, von Pirquet and ophthalmic reactions positive; 0.5 mg. tuberculin produced a rise of temperature to 101.4 F.

Case 5.—No history of exposure to tuberculosis; history of two years' cough; expectoration and pain in chest; dulness at right apex, with a few scattered râles to second space; dulness, diminished tactile fremitus, diminished expansion and a few moist râles at right base; intracutaneous reaction positive.

Case 6.—No history of exposure to tuberculosis; bilateral apical dulness; few fine râles at right first space; von Pirquet and intracutaneous reaction positive; reaction to 5 mg. tuberculin to 102.2 F.

Case 7.—Patient, aged 19. No history of exposure to tuberculosis; cough persisting after influenza; dulness and fine râles at left apex anteriorly and posteriorly; injection of 0.5 mg. tuberculin caused rise in temperature to 101 F.; locally moist râles at left supraspinous fossa; injection repeated with similar results.

Case 8.—Patent aged 21. No exposure to tuberculosis; hemoptysis two years ago; weakness, cough, slight expectoration, anorexia; dulness and dry râles after cough at right apex; impaired resonance, prolonged expiration and shower of fine râles at end of inspiration at left base; von Pirquet and intracutaneous reactions positive.

There are, then, ninety-two cases with demonstrated and eight with very probable pulmonary tuberculosis.

In ninety-six of these 100 cases, there was no evidence of premenstrual fever; i. e., no rise in temperature occurring within five days preceding the onset of a menstrual period. Neither did the patients show any elevation of the minimal temperature described by Saugman;[7] that is, an elevation of the lowest point in the diurnal temperature while still remaining below normal. The intermenstrual fever, described by von Voornveldt,[16] that is, a rise in temperature occurring thirteen to fourteen days after the onset of the preceding menstrual period, thus falling in the interval between two normal menses, was never present in my series. The four remaining cases, however, did show a rise in temperature; in detail they were as follows:

Case 9.—R. C., aged 16, single; case moderately advanced: observed twelve months, sixteen days; menstruated twelve times while under observation, and presented two premenstrual rises: (a) four days before menses, a rise from usual temperature of 99.5 F. to 101.6 F. for twenty-four hours; (b) three days before menses, rise to 103.2 F. for twenty-four hours.

Case 10.—L. K., aged 1[illegible], single; case moderately advanced; observed eleven months, twenty-three days; eleven periods; two premenstrual rises: (a) rise to 101 F. on third and fourth days before menses; usual temperature 99.2 F. to 99.8 F.; nine days preceding this same period, a rise to 100.8 F. had occurred; (b) rise to 101 F. twenty-four hours before menses; eight days preceding this a rise to 101.6 F. had occurred.

Case 11.—L. F., single; case incipient; tubercle bacilli in sputum; observed twelve months, twenty days. During this period the patient menstruated fourteen times; seven times preceding the onset of menstruation by twenty-four hours to forty-eight hours, and once, on first day of menstruation, her temperature reached 100 F. On eleven other occasions her temperature reached 100 F. and bore no relation to her menstrual period. A mitral and aortic endocarditis was a complication in this case. It is doubtful, therefore, whether an interdependence between the menstruation and tuberculosis can be maintained.

Case 12.—S. P., aged 20, married; case moderately advanced; observed nine months. A rise in temperature to 101.6 F. forty-eight hours preceding her menstrual period occurred on one occasion. It is interesting to note that just at this period the patient had a breast abscess.

It appears, therefore, that in the 100 cases of pulmonary tuberculosis, in all stages of the disease, here reported, only two uncomplicated cases of premenstrual fever occurred. It has been shown in a large series of cases (2,000)[14] that similar rises may occur in a large number of unrelated conditions. The proportion in which the rises occurred in my cases is out of all proportion to that assigned to it in literature; so I am forced to conclude that far too great stress has been laid on the incidence of premenstrual fever in tuberculosis. The theory of Riebold, which refers to the relation of ovulation to premenstrual fever, in dormant disease, is one which commends itself, but for which sufficient evidence is not yet present.

I wish to express my thanks to Dr. Kramer for aiding in the compilation of the statistics.

LEAD-POISONING IN ILLINOIS

ALICE HAMILTON, M.D.
Medical Investigator for the Illinois Commission on Occupational Diseases
CHICAGO

INTRODUCTION

Lead-poisoning in the United States is almost an unknown subject. Go through the literature and you will find here and there the report of an unusual case, an occasional compilation in a text-book, the material for which has had to be drawn from foreign sources; no experimental work, little study of the newer methods of diagnosis and no effort to gather statistical material or to bring the disease under the control of sanitarians.

When we began the study of the lead trades of Illinois we were assured that conditions here were very different from conditions in Europe; that lead-poisoning was a rarity, owing to our superior methods in industry. We found the reverse to be true. There is far more lead-poisoning in Illinois than in the same trades in England and Germany; at least in all those trades in which it has been possible to obtain anything like accurate figures. Far from being safer, American methods are often more dangerous than European, and while the German and English workman is not only better protected, but is under the supervision of an experienced physician, the American workman is, as a usual thing, under no medical supervision at all.

We found, in addition to the greater dangers arising from our methods of work, a very general ignorance of the hygiene of the lead trades on the part of the employ-

---

16: Von Voornveldt: Ztschr. f. Tuberk., 1905, p. 543

ers. In Europe and England employers have been carefully trained in industrial hygiene, but here they have been taught nothing. The result is a mortifying contrast between our industrial morbidity rate and that of other countries.

The fundamental difference does not lie in the attitude of the American employer as compared with his European brother. A perusal of Parliamentary bluebooks shows that English employers in the lead trades have been just as vigorous in their objection to outside control of their factories as Americans could be. Nor does it lie primarily in the difference between the two classes of employees, although the isolation of the foreign-born workmen in America, the class who fill our lead industries for the most part, has undoubtedly something to do with their neglected state.

The great contrast appears when we look at the attitude of the medical profession in Europe. There the health of the working classes, the problems of trade diseases, have been and are still studies worthy to engage the best intellects; here, we leave them to a few overworked practitioners with no leisure to use their material. There, it is the medical man who gathers statistics showing the prevalence of lead-poisoning, who outlines the necessary reforms, and gets them embodied in the shape of laws. We find in this field such men as Brouardel, Sommerfeld, Pieraccini, Glibert, Teleky, Rambousek, to mention only one representative from each country. Here it would be difficult to point to any activity on the part of the medical profession. The American Medical Association has never had a single session devoted to the diseases of industry.

It is this very general neglect of one of the most prevalent of trade diseases which has induced me to try to present the results of a study of industrial lead-poisoning in one state, in the hope that by calling attention to the many and varied industries in which lead is used, the lack of protection against lead-poisoning in American factories, and the large numbers of men poisoned, the medical profession may be induced to take that interest in the question without which no reform can be hoped for. The admirable results obtained in England and on the Continent show that much of the lead-poisoning in industry is avoidable.

STATISTICS GATHERED IN ILLINOIS

It is difficult to give the exact number of trades which involve the use of lead, because the classification of trades may be made in so many different ways. One can count manufactured articles, or processes in the manufacture of articles. If we follow the latter method, which was Layet's when he computed that in France 111 industrial processes involved the use of lead, we shall find on our list some seventy industrial processes in Illinois in which lead or its salts are handled and which have caused lead-poisoning in recent times. The list is far too long to give in full, but it may be of interest to mention some of the more unusual industries, such as making and selling wall-paper, polishing brass, polishing nickel, finishing cut-glass, cabinetmaking carried on in the same room with the sandpapering of white lead paint; holding lead-covered nails in the mouth while shingling a roof; working with aluminum foil (7 per cent. lead) in lithography; zinc-smelting; making ornamental tiles (with a non-fritted lead glaze); wrapping cigars in tin-foil; enameling bath-tubs; laying electric cables; stopping the inequalities of wood with white lead in making automobiles; assembling and recharging old storage battery plates; polishing handles of coffins.

That it was difficult to find individual cases, anyone who has attempted to compile statistics of this sort will readily understand. The physicians interviewed could often give valuable information, but seldom remembered the details of single cases, and I can recall but four, three of them foreign-born and trained, who kept written records, other than financial, of their cases. Consequently the 578 individuals on our list represent only a fraction of the real number, but as the record stands it is very startling when one compares it with the records in other countries. In the English and German reports we have statements based on the careful medical inspection of each man employed, repeated once a week or once a month, according to the danger of the trade. Our figures are based on the study of hospital and dispensary[2] records and on the statements of some of the physicians, not nearly all, of course, whose practice is drawn from the workers in the lead trades. Considering the necessarily incomplete character of our figures, one would expect them to fall far below those of England and Germany, but the reverse is true.

WHITE LEAD

One of the large white lead factories in England employs 182 men. No man was poisoned there during the year 1910. A Düsseldorf factory had two cases of lead-poisoning among 150 men during the same year. On the other hand, an Illinois factory with about 142 employed throughout the year had twenty-five cases last year, and another employing from seventy to eighty men had eleven cases during two months' time, which, if kept up during the year, would mean sixty-six cases. The British statistics for 1910 show that in the district of Newcastle-on-Tyne 1,320 persons were employed in white lead works; five cases of lead-poisoning were reported for that year, or one in 264 men employed. One case was fatal. The figures for the same year in Illinois are between 425 and 450 men employed; sixty-three known cases of poisoning, or one for every seven men employed; three fatal[3] cases. These figures are, of course, open to criticism, for there were more men employed in the course of the year than the pay-rolls indicate, and there were persons with lead-poisoning who did not visit hospitals or dispensaries. One physician, for instance, gave us the names of three patients from one white lead factory and said that he had had more than twenty additional cases during the year. We, of course, entered on our list only the three cases.

LEAD-SMELTING

Bad as are the conditions in the white lead trade, it has at least the advantage of being admittedly a dangerous occupation, and in three of the four Illinois factories regular medical supervision of the employees has been introduced, the first step toward controlling industrial lead-poisoning. This is not as yet true of the lead-smelting industry, in which large numbers of men suffer from lead-poisoning and no apparent effort is made to protect them from it. According to physicians practicing among these men, the great majority, if not all, become poisoned sooner or later, if they remain at work for more than a few months.

---

[2] These records are not always satisfactory. Meillere at the Brussels Congress of Industrial Hygiene, in 1910, said that to the average physician, as to the layman, lead-poisoning means colic or wrist-drop, an attitude of mind which he compared to that of a man who would say that [illegible] irium tremens. The large number of cases of [illegible] nephritis and heart disease among lead worke[illegible] the records of some hospitals and dispensaries, lead one to suspect that Meillere may be right.

[3] Our statistics of fatal cases are very incomplete. There is in the City of Chicago a curious ruling of the coroner's office by which every case of death by "poisoning" must be a coroner's case. Consequently, to save the family this needless annoyance, the physician makes out the death certificate for nephritis, arteriosclerosis, gastro-enteritis, etc.

I had the opportunity last summer to visit a large lead-smelting works at Ems, a place under the charge of one of Germany's foremost engineers and subject to the regular inspection of an experienced physician. The contrast between that plant and the best of ours in Illinois was so great that I could easily understand the difference in the morbidity rate of this trade in the two countries. Germany has systematically set herself to control conditions in lead-smelting and the results are shown by a fall in morbidity from 73.7 per cent. of all employed in 1885 to 0.8 per cent. in 1892.

STORAGE BATTERIES

Another trade listed abroad as very dangerous is the making of storage batteries or electric accumulators, as they are called over there. This does not seem even to be recognized as a lead trade in this country, either by physicians or factory inspectors. To make storage battery plates, grids of metallic lead with deep grooves must be filled and covered smoothly with a paste made of oxid of lead. It is a dusty trade and, in the absence of all regulation, a very dangerous one.

We found some cases of very rapidly developing and severe lead-poisoning among workers in storage batteries, and an amount of sickness quite disproportioned to the number of men employed, for Illinois has no large storage battery works. Two small places, one employing eighteen men, the other fifteen, sent each two men to hospitals with acute lead-poisoning within a period of nine months, while the Hart Accumulator Works in London, employing more than a hundred men, did not have one case of poisoning last year. The actual contrast would of course be more striking than this, for there were undoubtedly other cases of lead-poisoning in the Illinois factories. Only a small proportion of workmen go to hospitals for treatment.

PRINTING

It is unnecessary to give further figures showing the contrasting results of neglect in America and scientific control in Europe. That point is certainly clear. There are, however, some interesting facts concerning the all-important subject of occupation which were brought out during this investigation. The printer's trade was found to be much more dangerous than should be the case in these days of linotypes. This is a trade which suffers greatly from lack of ordinary hygienic control; accumulations of lead dust, the practice of dry-sweeping, the use of unhooded melting kettles with no provision for the removal of fumes and an insufficient lavatory equipment—all these are avoidable evils, but they are the rule, not the exception.

The fifty-seven cases of lead-poisoning found among printers were probably all due to the neglect of ordinary precautions. We found, as Sternberg of Austria has noted, that lead-poisoning in printers tends to assume the slow, chronic form, and that, in addition to the fifty-seven typical cases, the death records of the Typographical Union show an unduly large mortality rate from nephritis, heart disease and apoplexy.

COMMERCIAL ILLUSTRATION

The mechanical or commercial artists are a class we had not suspected to be exposed to lead-poisoning. One does not see them mentioned in foreign statistics, and when I inquired about them of the Factory Inspection Department in London, I was told that no cases of lead-poisoning in artists were ever reported in Great Britain. The discovery of the fifteen cases on our lists came as the result of a conversation with a young artist who had been referred to me by his physician as an "unusual case of zinc-poisoning." The man's history was absolutely typical and analysis showed that the paint he supposed to be zinc-white was really white lead.

The artists seem to suffer more than any other one class from their physicians' lack of acquaintance with industrial processes. The patient assures his doctor that he is using no lead paints, for it is the policy of many engraving houses to withhold from their artists the fact that they are using a dangerous lead paint. Consequently all sorts of erroneous diagnoses are made.

The young man I interviewed had been urged by three physicians to have his appendix removed, and a friend of his, well known in the trade, actually had four abdominal operations before the development of a typical radial paralysis revealed the real nature of his trouble. These artists work chiefly with white paint, and we found that all but four of the seventy-four places visited use white lead. The paint brushes are very fine and in order to get just the right degree of moisture and a fine point, the artists put their brushes in their mouths. In addition they use an "air-brush," worked with compressed air, which sends a stream of finely divided white paint over the picture and which is also used to blow off the superfluous paint after it is dry. Owing to the fact that it is a highly skilled, well-paid trade, the men are loth to leave it, and among the fifteen cases there were some of very severe poisoning.

LEAD-POISONING IN WOMEN

There are very few women on our lists and the fact that the lead trades in Illinois do not employ many women is a great advantage, for women are notoriously more susceptible to lead-poisoning than men. Our eighteen women were employed in polishing type with emery, making car-seals, dusting lead colors on litho-transfers, labeling paint-cans in an atmosphere of white lead dust, working with aluminum foil, making artificial flowers, wrapping cigars in tinfoil; one was a commercial artist.

The lead trades of Illinois are not as important as those of some of the large Eastern manufacturing states. Illinois has no large pottery works using lead glazes, or lead glass works or storage battery works of any importance, or rubber works in which white lead is used. There are probably several states in the Union which would yield a much larger return than Illinois to such an inquiry as this. Among the industries classed as lead trades in other countries, but not found in Illinois, are the weighting of silk, lace and passementerie with lead, file-cutting, polishing jewels, making white straw hats, white gloves, using lead glazes for pottery, enameled signs, etc., and making rubber goods. Lead-poisoning is undoubtedly an important trade disease in every state in the Union, for even those states which have little manufacturing have large numbers of painters and printers.

The general subject of lead-poisoning is too well known to need discussion, but it may be of value to give briefly the results of very recent studies in diagnosis and experimental pathology, especially as some of them are to be found only in the reports of the International Congresses on Industrial Hygiene, which are not easily accessible.

DIAGNOSIS OF LEAD-POISONING

The most important point in the diagnosis is universally stated to be the history of the patient's occupation, and this of course assumes, on the part of the diagnostician, an acquaintance with the industrial processes which involve the use of lead. One point should be mentioned in this connection, and that is the latest theory as to the localization of lead paralysis. It used to be assumed that lead had a selective action on certain muscles or certain nerves—according as this paralysis was held to be myogenic or neurogenic—first, the extensor muscles of the fingers and wrist; second, the muscles of the shoulder; third, the extensors of the foot. But close study of the motions involved in those processes in which lead-poisoning occurs, has led to the belief that overwork is the determining factor (Edinger, Teleky). The group of muscles involved in the paralysis of painters and printers includes those of the forearm and hand. Storage battery workers suffer from paralysis of the muscles of the shoulder (Labbé). File-makers grasp the chisel with the left hand, and have paralysis of the left fingers and thumb (Bernhardt, Leichtentritt). Children, who use their legs more than their arms, have paralysis of the leg muscles (Escherich, Variot); laborers, the muscles of the shoulders and legs (Pieraccini).

It can easily be seen, then, that the diagnosis of lead-poisoning in a case of paralysis may depend largely, if not entirely, on the physician's knowledge of the details of his patient's industrial history. His anamnesis may otherwise be of little value, for Tanquerel des Planches found that fourteen of his 200 patients with lead paralysis had no history of colic.

Next to the history the most important place has been assigned now to one diagnostic sign, now to another. At the Milan Congress of Industrial Hygiene in 1906, basophilic granulation of the red corpuscles was agreed on as the earliest and most unfailing diagnostic sign, but at the congress held in Brussels last September a change in opinion was evident. Biondi insists that the granules are merely evidence of the formation of new cells and as this process is intermittent the cells may be present one hour and absent the next, depending on the activity of the hematopoietic tissues. Even if present they must not be regarded as significant unless they reach appreciable numbers, according to P. Schmidt. At least 100 out of 1,000,000 red cells must contain basophilic granules and a count of as many as 300 to 3,000 is usual in lead-poisoning. Oliver stated that he did not find basophilia in most of his cases, and thought the diagnostic value of this sign very dubious. Rambousek failed to produce basophilia experimentally in rabbits which were undoubtedly lead-poisoned. The general verdict of the Brussels congress was that basophilic granulation of the red cells is a good positive, but a bad negative sign.

The value of the procedure advised by Du Moulin, smearing the carefully washed skin with sodium sulphid to produce the black sulphid of lead, has been much criticized of late, especially by von Jaksch and Rambousek, and will probably never be generally used.

As for the search for lead in the urine, there is a wide divergence of opinion between authorities. Oliver finds it present in almost all cases, and regards the test as one of the greatest importance. He found lead in the urine of a woman who had symptoms suggestive of lead-poisoning nineteen years after she had given up work in lead, during which time she had not been in any ascertainable way exposed to lead. Oliver frequently finds lead in the urine of patients with old chronic cases, and Edsall makes the same statement. Agasse, Lafont and Heim also state that lead can always be found in the urine in cases of lead-poisoning. On the other hand, von Jaksch says that the search for lead in the urine in the later stages of chronic lead-poisoning is negative, although lead is present in acute poisoning and in the early stages of chronic. Rambousek and Pieraccini both advise testing the stools for lead instead of the urine. They find lead in the feces constantly, but they doubt whether the kidneys play much part in its elimination.

The lead line on the margin of the gums, so valuable a confirmatory sign when present, is absent in some otherwise well-marked cases.

It is therefore generally held that plumbism is too variable in its development for any one sign or symptom to be regarded as diagnostic. The following is the group of symptoms which, when present, point to lead-poisoning: pallor, due to vascular spasm and disproportioned to the degree of anemia, foul breath, caries of teeth, gingivitis, loss of appetite, increased by the disagreeable taste in the mouth, recurrent attacks of weakness which may render fine work impossible, spots before the eyes, itching around the eyes, gastro-intestinal disturbances, diarrhea or constipation, loss of flesh, showing especially in the cheeks. If these symptoms, each one slight in itself, are present in a lead-worker, T. Weyl would diagnose lead-poisoning in an early stage. When colic has come on, the general vascular spasm is shown in the great pallor, the absence of sweat, even with extreme pain and restlessness, the slow hard pulse, low temperature, retraction of the abdomen, strangury and unconquerable constipation. Dyspnea from spasm of the smooth muscles and sudden, severe myalgia, especially in the flexors of the legs may accompany the colic (Weyl). Oliver finds that the pain is often localized on one side and that the pupils may be unequally contracted, the one on the affected side being the smaller. In such cases pressure on the pneumogastric nerve in the neck on the affected side shows great tenderness in this nerve. Potain finds the liver contracted during the attack of colic, and returning to its normal size after the attack is over, another result of the vascular spasm.

ABSORPTION

The question of absorption of lead is of great practical importance. For many years it was a disputed point whether the skin or the intestinal tract was the chief channel of entrance for the lead salts, but now it is conceded that the intestinal mucosa, including that of the mouth, plays by far the most important part. The English have of late laid great stress on the inhalation of dust as a cause of lead-poisoning, and Goadby reported to the Brussels Congress the result of studies on animals showing that lead could be demonstrated in the lung capillaries of cats which had breathed red and white lead dust. German authorities concede the importance of dust but believe that the greater part of that which is breathed into the mouth is swallowed.

As for the skin, it is admitted by all that water-soluble salts of lead, such as the acetate, chlorid and nitrate, may be absorbed through the skin, but that this is slow and requires long exposure. The non-soluble or poorly soluble salts are thought by some to be changed by contact with the fatty acids in the sweat into soluble compounds. It is held by these observers that in summer while the skin is very active it may be an important channel of absorption. On the other hand, Leyman says that skin absorption of non-water-soluble lead compounds has never been proved and he does not believe it of the least importance in industrial poisoning. To this Weyl, Toth, Legge, Oliver and Sommerfeld agree. Edsall thinks skin absorption relatively unimportant.

A large single dose of white or red lead is required to bring on symptoms of intoxication, but as lead is a cumulative poison, very small daily doses may be enough to give rise finally to the severest symptoms. Brouardel says that poisoning may follow the ingestion of no more than 1 mg. daily. It is of course only a question of disturbing the equilibrium between absorption and elimination, so that if the dose is suddenly increased or if there is a check to elimination, storing up of the lead begins.

PROPHYLAXIS

It would not seem logical to close without saying anything on the subject of prevention of lead-poisoning. As far as industrial poisoning goes, preventive measures have been worked out with great care by foreign governments and we have only to avail ourselves of the fruits of their experience.

The first requisite is the abolition of dust. Where this is impossible, and unfortunately American methods are much dustier than European, the workman must be protected by a respirator, although it should be remembered that no respirator is really an efficient shield against dust. Men obliged to work in lead dust should be given short hours, for fatigue is one of the strongest predisposing causes of lead-poisoning. Another necessary regulation concerns food. No man should be allowed to begin work fasting. Ample washing and bathing facilities and ample time to use them must be provided, and the men must be obliged to make use of them. If this is done, if dust is abolished and the men not allowed to eat lead[4] or carry it home on their persons, they can work in it with fairly little risk. I saw white lead workers in English and German factories very badly smeared with the lead while at work, yet the records showed no cases of poisoning.

Another necessary part of prevention, one most necessary in America, is the elimination of the casual shifting labor. We found in our study of the lead trades in Illinois that many newly arrived non-English-speaking Slavs, Italians and Greeks were engaged in the more dangerous processes of the lead industries and that they had little idea of the danger to which they were exposed, still less of how to guard against it. When such a man develops symptoms of acute plumbism he leaves his work and another ignorant immigrant takes his place, so that there is a constant procession of untrained men in and out of the lead trades. This condition is notoriously bad. In Germany statistics have shown that the amount of lead-poisoning in the white lead industry is in direct proportion to the number of casual laborers employed, and Oliver makes the same statement for England.

The regular medical inspection which is required by law in most foreign countries makes it possible to detect and remove susceptible workers and to abort a threatened attack of colic. There are factories in Illinois in which this feature has been voluntarily introduced by the employers and the bill now pending before the legislature will make it compulsory.

Legislation to regulate the poisonous trades is much needed in every state, but the first logical step toward it is a study of the conditions in that state, a task which naturally belongs to us physicians.

800 South Halsted Street.

THE VALUE OF ANIMAL EXPERIMENTATION AS ILLUSTRATED BY RECENT ADVANCES IN THE STUDY OF SYPHILIS *

JOHN W. CHURCHMAN, M.D.
Instructor in Surgery, the Johns Hopkins University; Formerly Resident Surgeon, the Johns Hopkins Hospital
BALTIMORE

I. INTRODUCTION

No one who is alive to the nature of physical pain or aware of the charm of the domestic animals could fail to sympathize with an inquiry into the warrant for animal experiments. It has always seemed odd, it is true, that this critical demand should not only begin with, but often single out for its entire attention, the one human activity involving animal sacrifice which has for its aim the relief of human distress; and that the good souls who become so concerned over one etherized dog, can regard with indifference the packing industry—with its wholesale slaughter to appease appetite; or the fur industry—with its reckless massacres to satisfy vanity; or the fisheries—consigning myriads of helpless beings to slow death by drowning in the air.

Nevertheless, those who are responsible for deliberate experiments on animals recognize the request for its grounds of justification, as a perfectly reasonable one. If the discussion is one in which facts may be offered as evidence, it ought to be a simple matter to determine whether or not the achievements of the experimental method justify its continuance. The history of the subject is an open book; and in commending it to the honest inquirer, medicine need speak in no apologetic tone. Abundant facts for a final decision of the question would come to light through a study of bacteriology and surgical asepsis—a whole science based on experimentation; or of the acute diseases for which specific cures have been determined (malaria, diphtheria, cerebrospinal meningitis); or of the plagues which may be absolutely prevented by hygienic and therapeutic measures (malaria, diphtheria, yellow fever, small-pox, rabies, tetanus); or of the hospital plagues which aseptic technic has almost abolished (erysipelas, blood-poisoning, hospital gangrene); or of the developments which have made every portion of the body accessible to surgery; or of the triumphs of obstetrics, which have reduced the appalling dangers of childbed fever to an almost negligible minimum. Even then only the most striking conquests of medicine would have been considered; and their significance would not have been even approximately grasped by those unfamiliar with the difficulties encountered by medicine at every step forward.

Nowhere, however, can the value of animal experimentation be so satisfactorily tested as in a study of the history of syphilis.

II. THE SOCIAL IMPORTANCE OF SYPHILIS

A just estimate of the value of animal experimentation in the development of the knowledge of syphilis is of vital interest because of the importance of the disease in the community. This is an importance usually overlooked by the public, whose interest is attracted by the more deadly plagues. Yet it is well within the limits of conservatism to say—so wide-spread is the disease, so calamitous and far-reaching are its effects—that none surpasses it, and few equal it in hygienic importance. The attitude of the public toward experimentation undertaken to extend our knowledge of this disease is then, obviously, by no means a matter of indifference.

---

[4] In many Illinois factories it is customary for foremen to encourage the men to chew tobacco, under the impression that the expectoration clears the mouth of lead dust. In Europe and England tobacco chewing in lead works is forbidden by law, for the sanitarians hold that lead is carried into the mouth by a plug of tobacco which has been lying in lead-smeared clothes and is handled with lead-smeared fingers.

* Editor's Note: This is Pamphlet 20 in the Defense of Research series. A list will be sent on request.

Wide-spread as the disease undoubtedly is, we have no means of determining its exact extent with accuracy; so many cases go unreported, and so many of the late effects of the disease unrecognized, that all our estimates are underestimates. Yet even so, the figures are sufficiently striking. LeNoir, after a study of nine years, reported at the International Congress in Brussels that between 13 per cent. and 15 per cent. of the male adults of Paris were syphilitic; in other words, that in this city alone, and considering only the male sex, there were 125,000 cases of the disease. These figures were confirmed by Fournier;[1] yet they by no means give even an approximate idea of the extent of the disease, for they take no adequate account of the ravages of late hereditary and parasyphilitic processes.

Syphilis in its acute stages is not a frequent cause of death; and examination of mortality statistics would, therefore, hardly be expected to demonstrate the extent of its ravages — as it might be expected to do, for instance, in the case of typhoid fever. Yet some idea of its spread and significance may be obtained by a consideration of the attitude of insurance toward it. Runeberg[2] found that, including certain apoplexies, probably syphilitic in origin, the mortality from the disease was about 15 per cent. — the total being second only to that of tuberculosis which caused 21 per cent. of the deaths. These figures, which may be somewhat higher than other statistics would justify, assume added importance when it is remembered that they represent the facts existing among the insured, that is to say, the most vigorous portion of the population. The damage done by the disease consists largely in its lowering the standard of average health, paving the way for other diseases and possibly laying the foundation for mental degeneration and alienation. The extent of these secondary effects can only be estimated. Most insurance companies require that four or five years shall have elapsed after the disappearance of the last symptoms of the disease; and no applicant who has had syphilis is given a policy which will keep him on the company's books after his fifty-fifth year. Greene[3] goes even further, and firmly believes insurance at ordinary rates (even after an interval of five years) to be an error. Under no circumstances would he advise a straight life policy to be issued to a man who has a syphilitic history.

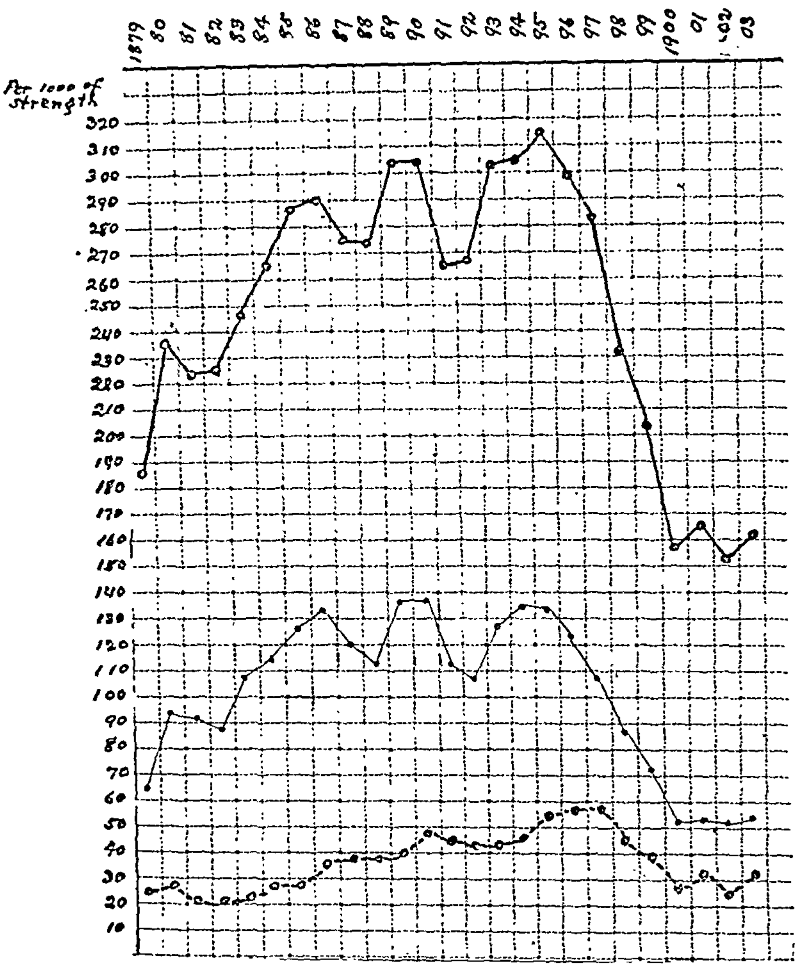
III. SYPHILIS IN THE ARMY

Consider the state of affairs in national organizations in which men are under constant discipline and something like accurate statistics may be obtained. Table 1 represents the admission-rate per 1,000 of strength for syphilis among the British troops in India.

TABLE 1.—Syphilis Among British Troops in India per 1,000 of Admissions

Year.	Primary Syphilis, Inc. Soft Chancre.*	Secondary Syphilis.
1887	142.1	29.4
1888	142.1	32.4
1889	225.1	51.2
1890	220.7	66.3
1893	213.6	61.6
1894	248.1	74.6
1895	239.0	84.9
1896	226.4	97.7
1897	201.7	101.9

*It must be observed that the figures in this column include certain non-syphilitic venereal lesions. The above table is from French: Syphilis in the Army.



Chart, taken from French: Syphilis in the Army, Chart III, Appendix III. The upper, heavy line represents the incidence of all venereal disease; the middle, fine line represents the incidence of primary venereal sores; the lower, dotted line represents the incidence of secondary syphilis.

It is the study of such figures as these which leads experts like Sir Alfred Keogh[4] to write:

> It may be stated without fear of contradiction, that there is no disease, with the possible exception of malaria, that has so important an influence on the efficiency of an army or navy as syphilis. Other diseases doubtless are more deadly and consequently attract more attention; no other is so lasting in its effects, or so persistent in its attack on the bodily strength of the man who has once acquired it. A soldier gets enteric fever and either dies or recovers. Out of a hundred such, it may safely be prophesied that eighty will survive, and of these seventy, at least, be not only none the worse for their experience, but eventually all the more efficient for field ser-

[2] Osler and Churchman: Chapter on Syphilis, Osler's Modern Medicine, iii, 495.

[3] Greene: Examination for Life-Insurance, p. 118.

[4] Keogh: Introduction to D'Arcy Power and Murphy's System of Syphilis, vol. vi.

vice in consequence of it. . . On the other hand, thirty men get syphilis, and not one of these can ever be considered the man he was before.

With this expert opinion in mind, a glance at the accompanying chart will convince any one of the tremendously crippling power of syphilis in an army. It represents the facts for the British army at home and abroad.

These statistics may be supplemented by two further tables, showing the incidence of syphilis in the armies of Great Britain and the United States.

TABLE 2.—THE INCIDENCE OF SYPHILIS IN THE BRITISH ARMY AT HOME AND ABROAD *

Year.	Strength.	Admissions for Syphilis.	Admissions Per 1,000 of Strength.
1894	203,469	27,436	145.01
1895	200,681	28,081	140.41
1903	282,182	12,668	52.31
1904	244,425	9,219	37.72
1905	240,075	7,039	29.32
1906	230,128	5,958	25.89
1907	217,844	5,033	23.11
1908	215,647	4,137	19.19

*The slight discrepancies between figures in this table and those in the previous chart are apparently due to the fact that in the chart a certain small number of non-luetic lesions are included under "primary venereal sores." Tables 2 and 3 are from D'Arcy Power and Murphy: System of Syphilis, Volume VI.

TABLE 3.—THE OCCURRENCE OF SYPHILIS IN THE ARMY OF THE UNITED STATES

Year.	Strength.	Admissions for Syphilis.	Admissions Per 1,000 of Strength.
1903	71,679	1,676	23.36
1904	59,671	1,525	25.56
1905	55,619	1,953	35.11
1906	53,573	1,869	34.89
1907	53,249	1,534	28.80
1908	50,705	1,436	28.32
1909	62,263	1,592	25.57

Syphilis is thus seen to be one of the most important causes of military inefficiency, even under the best conditions of medical supervision. Given the least leeway it may break out to an appalling extent, as it did among the British troops in the Peninsula, who christened it the "Black Lion of Portugal."[5]

IV. THE SERIOUS NATURE OF SYPHILIS

The wide incidence of syphilis is, then, sufficiently evident. But the great menace of the disease, not only to the two arms of the national defence, but to the health —even to the existence—of the nation as a whole, can be made plain only by a consideration of the calamitous nature of its clinical manifestations.

1. *Danger to the Individual.*—The dangers of the disease to the afflicted individual himself are perhaps roughly appreciated, though it is doubtful if the serious handicap to work, which the compromising and disagreeable secondary symptoms cause, is sufficiently understood. What is certain is that the laity and a majority of physicians wholly fail to appreciate the grave and often fatal nature of the tertiary manifestations. These are particularly pathetic, because they may appear in the prime of life, years after the initial lesion has been forgotten as a thing of the past; and may absolutely incapacitate an otherwise healthy man, who has become involved in the responsibilities of a husband and father. Nothing is more distressing than the sinister predilection of tertiary syphilis for the nervous system. Of 5,749 syphilitic patients studied by Fournier,[6] 758 developed syphilis of the brain, and 1,099 others syphilis of the cord and nerves. That is to say, nearly one out of every three of the patients exhibited syphilis of the nervous system. And if to the multiform manifestations of the disease in its active stage be added the parasyphilitic phenomena — serious, incapacitating and as yet not amenable to treatment — some faint idea may be gained of the far-reaching effect of the disease on the individual.

2. *Danger to the Family.*—But it is as a menace to the family that this disease appears most formidable. No catastrophe can be more disastrous than its spread by the marital relation; no spectacle more dreadful than its transmission to innocent children.

It is the wife, of course, who is most often—though not *always*—innocently infected; and when this occurs, disasters of many kinds follow. The woman herself is submitted to the discomfort, the risk and the degradation of syphilis; and no consequence of the disease can be more distressing. Nor is this occurrence a rare one. Those who regard syphilis as the peculiar property of the underworld, and eye its victims with suspicion, would be surprised at the facts brought out by Fournier[6] who, in a study of 100 syphilitic women, found one in every five to have been innocently infected by her lawful husband. Such a woman must suffer not only in her own body; she must expose her children to the most serious form of syphilitic heredity—mixed heredity. It is only natural that such a train of affairs once started often ends in the dissolution of the family. Even if actual divorce does not ensue, the family ties fail to stand the test; affection and respect die; and we have the melancholy spectacle of a house divided against itself. Moreover, not infrequently, economic ruin ensues through incapacitation of the head of the family and the household becomes a public burden.

3. *Danger to Posterity.*—But this foul disease appears most foul in its dastardly attacks on the second and third generations; and all other features fade beside its importance in heredity. Indeed, the need of protecting innocent children from syphilitic infection is the complete answer to those who object to the removal of the consequences of syphilis as inciting to vice.

An infant mortality astonishingly high is what the disease produces. In many instances this amounts to a complete annihilation of posterity. Ninety women studied by Fournier—all seen in private practice, all of good constitution and surrounded by a favorable environment of hygiene and wealth—became pregnant during the first year of the disease ("the year of terror"). Fifty of these women aborted, thirty-eight infants died soon after birth, and only two children survived—a mortality of 97.7 per cent.! Another study included 200 men who had married while syphilitic, but who failed to contaminate their wives. Four hundred and three pregnancies for which these men were responsible resulted in 288 living children and 115 still-births, abortions and early deaths. Instances of excessive infantile mortality could be indefinitely multiplied. Ribemont-Dessaignes, for instance, reports a woman who contracted syphilis from her husband; she became pregnant nineteen times, had five still-births and gave birth to fourteen children, every one of whom died under 6 months of age. "A child," writes Fournier, "conceived by a woman in the course of recent syphilis is almost certainly condemned to death."

But to this dreadful indictment must be added the woful heritage which syphilitic parents bequeath to the children who do manage to survive. Fragile infants—a prey to every infection; monsters; pathetic and wizened mannikins; idiots; normal children, condemned to a late syphilitic heredity at the second dentition or at puberty—this is the spawn of syphilis. Nor does the trail of the beast stop here; the heritage which these unfortunates receive they pass on to their descendants; and the effects of the disease in heredity may be traced through three generations (Gilbert, Caubert, Étienne). "To cleanse the brothel," writes Fournier, "is not only to protect those who frequent it; it is also to protect the family hearth, the honest woman, the child and the race."

---

[5] Ricord: Illustrations of Syphilis. Historical introduction in Belton's Translation.

[6] Practically all that is here written on the dangers of syphilis is taken from Fournier's Treatment and Prophylaxis of Syphilis, Marshall's Translation, ed. 1906, a book that should be familiar to everyone interested in the disease and its relation to society.

That syphilis is a formidable national scourge and that complete knowledge of it is of fundamental hygienic importance may, then, be regarded as established.

V. KNOWLEDGE OF SYPHILIS GAINED BY THE EMPIRICAL METHOD

We have next to inquire into the state of medical knowledge of the disease before animal experimentation began. This will be particularly instructive; because by comparing the knowledge thus slowly acquired, through long years of simple observation, with the rapid advances made in the few years in which the study of the disease by the experimental method has been possible, we get a vivid picture of what productive animal experimentation, now adding daily to our knowledge of syphilis, really means.

It may be said at once that the information about syphilis which medicine was able to accumulate, entirely without the aid of animal experiment, was marvelously complete and accurate. Here is a disease, protean in its manifestations, affecting probably every organ in the body, pursuing a long and insidious course, almost identical in its initial forms with other simple venereal infections and possessing a peculiar power of mimicry, whereby it can simulate minutely the signs and symptoms of numerous other diseases. The conditions could hardly present greater difficulties. Yet, purely by the method of clinical observation, chaos was gradually reduced to order. It is true that this result was many long years achieving. At the time of the European syphilitic pandemic (1494) enormous confusion prevailed as to the nature of the various venereal infections. The difficult problem was gradually solved—but how gradually, may be realized when it is recalled that not until nearly 400 years had elapsed was the question of the dualistic nature of syphilitic and non-syphilitic venereal infections settled.

Quite as interesting as the completeness of the clinician's acquaintance with syphilis in pre-experimental days, was the satisfactory condition of its therapeutics. Working by purely empirical methods and entirely without a rational or an experimental basis, the early physicians found and developed a method of treatment by which the disease could almost always be controlled, and, in a large majority of cases, absolutely cured. The choice of mercury—recommended in syphilis by the Galenists for the most absurd of reasons—happened to be a lucky guess.

In 1836 the administration of potassium iodid in syphilis was recommended by Wallace. This date is an important one in the history of the disease: for it does more than mark the year of a valuable contribution to therapeutics. It marks, too, the end of important advance in our knowledge of the disease; for from that year until the recent successful experimental work on animals, medicine stood practically still so far as syphilis was concerned. A few advances were, of course, made; the debate as to the dual nature of luetic and non-luetic lesions was brought to a conclusion by the French school (Bassereau, Fournier, Clerc, Ricord); certain unrecognized syphilitic lesions were described (arthropathies by Richet, bursopathies by Verneuil); extensive statistical studies were made by Fournier and others; and the importance of parasyphilitic and late hereditary forms was recognized and emphasized. But no really new light was thrown on the disease. Clinical study had about reached the limit of its possibilities.

VI. DEFICIENCIES IN PRE-EXPERIMENTAL KNOWLEDGE OF SYPHILIS

It is essential for one interested in good faith in determining the value of experiments on animals in syphilis to ask whether there was any need that this intimate, and in many respects, satisfactory clinical and therapeutic knowledge be supplemented by facts which animal experimentation might supply. Was it merely that scientific curiosity craved satisfaction? Or were there real hygienic needs to be met, and to be met only by the study of the disease in animals?

That a vital demand for further knowledge existed becomes at once apparent when it is stated that, complete as our knowledge of syphilis was, there were a number of points at which it was replaced by ignorance as complete; and that this ignorance concerned certain fundamental features of the disease.

In the first place, it has often been impossible to make an early diagnosis. The first sign of syphilis (the chancre) usually appears about three weeks after infection has occurred. When it does appear its nature is often so uncertain that further phenomena must be awaited before the prolonged and disagreeable treatment can be instituted. If specific treatment is undertaken immediately, the sore will disappear, secondary symptoms may never present themselves, a positive diagnosis may never be made and the treatment—which, to be effective, must be carried on thoroughly over a period of years—will at first be half-heartedly undertaken and in a short time discontinued. On the other hand, if treatment is not promptly begun, valuable days, even weeks, pass before the disease can be positively recognized and attacked.

In the next place, positive diagnosis in the later stages of the disease is often impossible. Those unfamiliar with the protean manifestations of syphilis have no conception of the difficulty it may present in diagnosis. Even the most experienced physicians are often unable to tell whether a given condition is syphilitic or not.

But a graver deficiency in our knowledge of this disease, is our inability to recognize it in its "latent" forms. In these cases the infection, though still present and likely to break out at any time or to be passed on to others, is not at the moment producing any obvious signs or symptoms. It is this form of the disease which contributes largely to the danger of syphilis among prostitutes; for the existence of latent syphilis, though a real menace to the community, may escape the most careful medical inspection. A syphilitic woman could quite well be the source of widespread infection and yet possess a clean bill of health on the absence of obvious signs.

Moreover, we have never known how long it was necessary to continue treatment before a complete cure was obtained. As our knowledge of the disease advanced, it became clear that a longer and longer duration of treatment was necessary for safety; and it is now rather arbitrarily estimated at about three years. But this is only an estimate. And how unsafe it is to proceed, in this matter, on an estimate becomes apparent when the importance of the disease to marriage is borne in mind.

All physicians are agreed that no syphilitic should marry until the disease has been positively cured; but they have no way of telling just when cure has been effected; and have, therefore, always lacked the necessary data for intelligent advice to their patients.

Finally, so long as the cause of the disease was unknown and the possibility of its study by the methods of reproduction in animals excluded, advances in the knowledge of the disease—such as these methods had made possible in the case, for example, of suppuration—were quite out of the question.

VII. WHAT EXPERIMENTAL RESEARCH HAS ACHIEVED IN THE CASE OF SYPHILIS

1. *Successful Reproduction in Animals.*—Previous to 1903 animal experimentation practically did not exist so far as syphilis is concerned. So many of the attempts to transmit the disease to animals had been unsuccessful, and so difficult was it to control the supposedly successful results, that the general attitude toward the subject was one of apathy. Certain observers had indeed reported successful transmission to animals. Auzias-Turenne,[7] for example, claimed to have inoculated the cat; LeGros and Lancereaux,[8] the pig; and an occasional success had been obtained in monkeys (Klebs,[9] Martineau and Hamonic,[10] Nicolle[11] and others). But the successes had been only occasional and could not be substantiated by independent observers.

In 1903, however, the first communication of Metchnikoff and Roux[12] was published by the Pasteur Institute. The authors reported the undoubtedly successful transmission of syphilis to a two-year-old female chimpanzee; and the equally successful inoculation of a male chimpanzee with material taken from the first animal. Several bonnet monkeys (*M. sinicus*) were also successfully inoculated; but certain species (e. g., the mandrils) seemed to be insusceptible. These experiments were promptly repeated by Lassar[13] and the results confirmed.

The successful inoculation of animals immediately opened up a dozen avenues of research, and a second communication soon appeared from the same workers.[14] Here, continuation of the inoculation experiments was reported; and it was apparently demonstrated that monkeys might be divided into two groups, according to their susceptibility to syphilis — the anthropoids approaching the lower races of man in susceptibility, the mandrils and maimons exhibiting a complete natural immunity to the disease. The idea was therefore confirmed, which had previously been advanced by others, that failure to use susceptible animals probably explained much of the inconsistency of the experimental work done before this time. Additional confirmation of this work soon came from Neisser,[15] who reported successful inoculations of chimpanzees, orang-outangs and a gibbon. In 1904, Metchnikoff and Roux's third communication[16] appeared. Here the particularly interesting point was made that the syphilitic virus would not pass through a Berkefeld filter. Klingmüller and Baermann[17] had previously made the same assertion *after having inoculated themselves with human syphilitic material* which had been passed through a Berkefeld filter. Finally, the two workers at the Pasteur Institute published their conviction, in a fourth communication,[18] that the chimpanzee, by reason of its susceptibility to syphilis and the similarity of the symptoms produced with those seen in human beings, was the most suitable animal for experimental purposes. More important still, they were able to confirm the work of Schaudinn, which had meanwhile appeared, by finding the *Spirochæta pallida*[19] in 74 per cent. of thirty-one syphilitic monkeys. Thus did the two lines of research promptly cross.

Experimental work on animals other than monkeys was never very conclusive until Bertarelli[20] reported the successful inoculation of the cornea in rabbits. A similar result had been obtained by Haensell;[21] and Bertarelli's observations were promptly confirmed by Hoffmann and Brüning,[22] by Scherber,[23] and by Greef and Clausen.[24]

Thus, in a few short years the technic of animal experimentation—so fruitful in other fields—has been developed for syphilis. It is impossible to exaggerate the importance of this advance, which touches the whole dreary prospect of syphilis with hope. The work of Metchnikoff and Roux on susceptibility and immunity, of Finger and Landsteiner[25] on the infectiousness of tertiary lesions and of semen, of Neisser on the syphilitic testicle: these are a few instances of the way in which new avenues of progress were immediately opened up and promptly traveled by eager scientists. The prevention of syphilis, which previously seemed an utopian dream, became—once the transmission of the disease to animals was assured—a reasonable, if remote, hope; and there was not a single dark crevice into which this discovery did not throw encouraging light.

2. *Discovery of the Cause of Syphilis.*—The year 1905 marks the beginning of a new era in the history of syphilis; for a publication which then appeared put an end to the long and weary search for the cause of the disease. The idea of a living contagium in syphilis had long been held, and the tale of the search for it is one to make the judicious grieve. But a new light broke with the appearance of the paper of Schaudinn and Hoffmann.[26] It was an epoch-making report, but it was a model of calmness. Despite the importance of the observations, the facts were cautiously stated and a discussion of their significance postponed until the accumulation of further data. The authors had found, they said, a characteristic, nonrefractile, delicate organism, from 4 to 14 microns in length, pointed at both ends, with numerous clear, tight, cork-screw-like spiral curves. It was readily distinguishable from other bacterial and protozoan forms, and had been found in numerous primary and secondary syphilitic lesions. Moreover, Metchnikoff had been able to demonstrate its presence in the primary lesion of an experimentally inoculated ape.

This paper immediately awakened a new interest in the subject throughout the world; and confirmatory evidence soon accumulated in enormous amounts.[27] Before long, what had at first been cautiously accepted as a probability bordering on certainty, became a certainty; the *Spirochæta pallida* of Schaudinn and Hoffmann withstood all efforts to disprove its etiologic relation to syphilis; and the long and weary search for the cause of the disease was at an end.

3. *Discovery of a Diagnostic Reaction Specific for Syphilis.*—Hardly less important than the discovery of the cause of syphilis, was the demonstration of a biologic reaction, the presence of which is absolute proof of the existence of the disease, even in the absence of signs or symptoms.[28] The very great value of such a reaction in cases of doubtful diagnosis, and particularly in latent syphilis, needs only to be mentioned to be appreciated. The reaction was discovered almost simultaneously by Wassermann, Neisser and Bruck,[29] and by Detre,[30] working independently, but with practically the same technic. The names of Bordet and Gengou[31] must, however, be borne in mind in this connection. These two pioneer observers (who also recognized the *Spirochæta pallida* before Schaudinn and just missed appreciating its significance) were the first to describe the general phenomenon of complement fixation (or deviation), of which the Wassermann reaction for syphilis is a modified example. *This highly theoretical investigation and the immensely practical application of it by Wassermann depended on animal experimentation at every step.*

The Wassermann reaction depends on the capacity which the serum of syphilitic patients has to fix complement in the presence of extracts of syphilitic tissue, or certain other alcoholic extracts. This fixation of complement is tested for by the use of a so-called hemolytic system, which consists of red blood-cells, and a serum capable, in the presence of complement, of hemolyzing them. It is impossible to define the reaction without the use of highly technical terms which would themselves require extensive definition. Here, one may simply state how the test is made. Extract of known syphilitic material and the blood-serum of the patient to be tested are mixed in a test-tube. Fresh guinea-pig serum is then added and the mixture incubated to allow complement-fixation to occur. The hemolytic system, which requires complement for the completion of the hemolysis, is next added. If the serum to be tested is not syphilitic, complement is not bound and hence is available for the use of the hemolytic system; hemolysis, therefore, proceeds, the red blood-corpuscles continue to be destroyed, the mixture becomes red in color and the test is negative. If, on the other hand, the serum is syphilitic, complement is bound, hemolysis inhibited, the red blood-cells not destroyed, the mixture not reddened, and the test is positive.

This test, while not absolutely constant, has turned out to be one of the most valuable of the biologic reactions. When the test is negative, syphilis is not excluded; but when positive, a diagnosis of syphilis is to be made with almost absolute certainty. It has already shown itself even more reliable than the Widal reaction; and no one familiar with typhoid fever is ignorant of the very great value of this diagnostic test.

4. *Discovery of a Specific Drug for Syphilis.*—It would be difficult to find in the history of medicine a more interesting and instructive story than the account of the work which led up to the discovery of salvarsan (606). When Ehrlich began his work years ago, syphilis was the last thing in his mind. He was interested at that time in the idea which possessed him that every living cell has a chemical affinity for some particular substance. This property of mutual attraction he called chemotropism; and in experimenting with dyestuffs he came upon a very pretty example of it in the selective affinity which methylene-blue exhibits for cells of the nervous system. If, then, such a specific affinity did exist, it seemed quite probable that it might also exist between certain drugs and certain parasites; and after some years of further experimentation Ehrlich was able to investigate this point. He believed that for each specific parasite, a specific curative drug could and would be found.[32] Because of the sleeping-sickness epidemic in Africa and because the disease is easily transferable to mice, Ehrlich began with a study of this affection. He succeeded, in connection with Weinberg, in producing a new dyestuff (trypan-red) which caused the organisms to disappear from experimentally inoculated mice in one injection. It was soon shown that parasites rapidly acquired a tolerance for such drugs and that, in order permanently to cure a parasitic disease, it was necessary to destroy every single parasite in the shortest possible time. Ehrlich's very difficult problem then became to produce a substance which was so specific for given parasites as completely to destroy them at one injection, but which was at the same time harmless to the infected animal itself. Starting, then, from atoxyl—an arsenic compound known to be efficacious in trypanosomiasis, but dangerous to the animal—Ehrlich proceeded to the solution of the problem. The task was one of colossal dimensions. Hundreds of substances had to be synthetized and then tested for toxicity on various species of animals. Of the large number of drugs made and tried, only about ten stood the test.

At about this stage in the work it was shown by Bertarelli and others, that syphilis could be transferred to rabbits; and Ehrlich turned his attention to the diseases caused by the spirilla and spironema: syphilis, relapsing fever and chicken spirillosis. In a short time a drug was produced—No. 606 in the series—which Hata found would definitely cure chicken spirillosis in a small, safe, dose, would completely sterilize a mouse infected with relapsing fever, and—in a dose one seventh of the *dosis tolerata*—was sufficient to cause the *Spirochæta pallida* to disappear from a syphilized rabbit.[33] Ehrlich repeated the experiments; the drug was again tested on dogs, *and on two of Professor Alt's assistants, who volunteered to demonstrate in this way the safety of the drug for*

---

[27] It is impossible to indicate even the more important articles. The early literature on the *Spirochæta pallida* is collected in a Leipsic thesis by Julius Glass, December, 1905; and by Herxheimer, in Lubarsch and Ostertag's Ergebnisse der Alleg. Path., Jahrgang, xi, Abteil. 1. The article by F. P. Gay in Internat. Clin., 1907, iii, series 17, p. 199, is accompanied by a useful bibliography.

[28] The reaction has been observed also in leprosy and in scarlet fever; but for practical purposes these exceptions do not impair its diagnostic value.

[33] The chemical name of this preparation is p.p.—dioxy=m.m.—diamido-arseno-benzol. It is used in the form of hydrochlorid of the sodium salt, which has the following structural formula:

human beings. It was then tried on patients. In order to make the test of the drug on human beings as convincing as possible, Ehrlich distributed 20,000 doses to clinicians of standing throughout the world, on the condition that certain rigid restrictions in administration be observed, and that the patients be kept in hospitals several days for observation. On the results thus obtained, Ehrlich will base his conclusions as to the value of the drug in the treatment of human syphilis. Those who have attempted to assemble, one at a time, 20,000 objects of any kind—say something as readily accessible as a canceled two-cent stamp—will appreciate something of the magnitude of this task, when they remember that the preparation of the dose of the drug, the necessary examination and subsequent observation of the patient, the preparation of the records, the critical examination of the results—are proceedings which represent hours of work for each individual case; and that this colossal task is merely the final stage in a research which has been going on for years. This point is worth calling to the attention of those who are accustomed to regard animal experimentation as child's play, undertaken at odd moments, by brutes who love to see animals squirm.

This account of the work of Ehrlich is the briefest possible sketch.[34] It conveys no idea whatever of the difficulty of the problems attacked, or of the genius displayed in overcoming them. It says nothing of several important contributions made to the theory of science, and to the practice of medicine, by the way. One of the earliest points brought out, for example, was a demonstration of the true chemical nature of atoxyl. Again, trypan-red—though used by Ehrlich against sleeping-sickness—was shown by Nuttall to be also effective in the widely distributed Texas fever of cattle. Salvarsan (606), sent by Ehrlich to Iversen in Russia, proved to be of very great value in the treatment of relapsing fever.

Of the exact value of the drug in syphilis it is too early to speak; the evidence is not yet all collected and has not been made public. Moreover, it is recognized as quite possible that a drug so powerful may have important deleterious effects; and until this point is cleared up by experience, any judgment as to its final place in medicine is ill-advised. It is, however, an open secret that astonishing results have been obtained. From the clinics of Wechselmann and many others, reports have already appeared which make it seem certain that—even if the final results fail to fulfil the early hopes—a contribution of the very first importance has been made to the therapeutics of syphilis.

But Ehrlich's work has been more than a contribution of this sort. He has founded a new science of chemotherapy, and has given a new vitality to pharmacology—hitherto interested largely in the toxic effects of drugs on normal animals. He prophesies a new era to be brought about by the interest of chemists like Baumann and Emil Fischer, and clinicians like von Mehring in practical therapeutics. "On the basis of years of experience in the laboratory," he writes, "I indeed believe I am justified in expressing the hope that, by carefully following the path [of chemotherapy] which I have sketched, a sure advance will be made."[35] These are the cautious and serious words of a serious man, whose talent and achievement place him in the very first rank. It is the opinions of such men which should be decisive in these matters.

This, then, is what animal experimentation has done for syphilis. In a period of about seven years the cause of the disease has been established, a specific reaction for its detection has been discovered, its successful transmission to animals has been accomplished, and a drug of apparently first-rate importance has been advanced for its treatment. Those who make practical achievement the final test of the value of experimental work. could hardly ask for more convincing evidence than these splendid results provide.

VIII. PRACTICAL VALUE OF RECENTLY ACQUIRED KNOWLEDGE OF SYPHILIS

To appreciate, however, the real significance of these advances it is necessary to do something more than merely state them. No one could possibly deny their importance, regarded simply as achievements. But it is conceivable that this might not be regarded as sufficient justification for them. "Do they," it might be asked, "represent merely the triumph of scientific curiosity over great natural obstacles; or have they really made medicine more efficient, by enabling it to deal better with this disease?"

It must, in reply, be at once stated, and stated with great emphasis, that there is not a single weak point in the medical attack on syphilis which recent animal experimentation has not strengthened; that complete knowledge has in many places replaced complete ignorance; that diagnosis has been made easy where it was previously difficult, and possible where it was previously out of the question; that the efficiency of treatment has been tremendously increased; and that the way has been indicated for the solution of many, if not all, of the difficulties which still remain.

In order to justify these extreme claims let me take up, in an itemized way, the deficiencies in our previous knowledge, which have already been indicated, and apply to them the facts which animal experimentation has supplied.

1. *Possibility of Early Diagnosis.*—An early diagnosis of syphilis is now possible. On the appearance of the initial lesion, we are able—by finding the recently discovered *Spirochæta pallida*—to make a positive diagnosis of the disease. The confusion with non-syphilitic genital lesions has become a thing of the past and it is no longer necessary to waste valuable time awaiting the appearance of secondary symptoms before treatment is begun.

2. *Increased Possibility of Positive Diagnosis.*—A positive diagnosis is now possible in many cases which previously went unrecognized. The Wassermann reaction and the demonstration of the *Spirochæta pallida* are of great importance in making the sometimes difficult differential diagnosis between syphilis and the host of affections which may simulate it—a diagnosis which, without these aids, was often simply not made.

3. *Recognition of Latent Syphilis.*—It is now possible, in a large majority of cases, to recognize "latent" syphilis. Heretofore, unless symptoms recognized as definitely syphilitic were present, we had no means of detecting the disease. Now, it is possible to say not only that a man has syphilis, but (in a fairly large proportion of cases) that he has had it. This is an advance of the very greatest importance. It enables us to recognize the syphilitic nature of many affections which might otherwise be badly treated. And it promises to be of value in the solution of the vexed problem of prostitution; for we are now able to tell, with a good deal of exactness, which prostitutes are infectious, and efficient hygienic control becomes a possibility. Indeed, the means for

---

[34] Marks, L. H.: Paul Ehrlich; the Man and His Work, McClure's Magazine, December, 1910; Schweitzer: Ehrlich's Chemotherapy—a New Science, Science, Dec. 9, 1910.

[35] Ehrlich: Ber. d. deutsch. chem. Gesellsch., xlii, No. 1.

the detection of the disease in the absence of symptoms, the means for its positive diagnosis, and the means for its cure, having been provided, it is now possible for the community—if it choose to make intelligent use of the knowledge—to rid prostitution of syphilis. And this means, in time, the abolition of the disease from the face of the earth. If this sounds like a utopian dream, one has but to recall small-pox, which once raged everywhere, but which medicine—with slender means at her disposal—finally overcame. Sufficient knowledge is now at hand to enable us to recognize and control the main foci of infection; proper use of this knowledge will eradicate syphilis, even though prostitution itself continue, as it quite well may, to flourish.

4. *Possibility of Ascertaining a Definite Cure.*—The time when a syphilitic patient may be regarded as cured, and not only free from the disease himself, but incapable of transmitting it to others, may now be known with practical exactness. The importance of this fact in relation to the question of marriage is evident. To the syphilitic patient anxious to marry, but equally anxious not to confer on his future wife and children the dangers of the disease, medicine has heretofore been able to give only halting advice. After three or four years of treatment she has allowed him to marry, but always with some misgivings. Now, she will certainly forbid his marriage if his Wassermann reaction is positive, no matter how long he has undergone treatment, or how complete is his freedom from symptoms; and she will allow the marriage confidently, if the reaction becomes negative and remains so without treatment. Moreover, if the state ever finds itself prepared to exercise an enlightened control over the physically unfit to prevent them from passing their burdens on to posterity, medicine stands ready to indicate to the state just what, so far as syphilis is concerned, constitutes unfitness.

5. *Proof of Infectiousness of the Tertiary Lesion.*—Not least of the contributions of experimentation has been the proof of the infectious nature of the tertiary lesions. This fact has only to be stated for its importance to be understood.

6. *Increased Activity with Regard to Syphilis.*—Finally, now that the cause of syphilis is known and methods for its study in animals are at hand, the lethargy of preexperimental days, in regard to syphilis, disappears, and is replaced by enthusiastic and hopeful activity. For it must be remembered that the study of syphilis by the use of animals is yet in its infancy; that only the bare beginnings have been made. The recently acquired knowledge of the disease is still in a fluid state; and it is difficult to estimate exactly what the ultimate value of the observations made, will be—as difficult as to prophesy the exact future position of every boat in a fishing fleet, making for harbor with favoring wind and current. Yet, the wind that blows is the wind of progress; the current is the current of hope; and the haven ahead is the harbor of health. Behind, lies the troubled sea of chaos and despair. Anyone who thinks this a mere figure of speech is invited to consider the incalculable value of the achievements of recent experimentations for the host of innocent women, menaced by this disease, and the great army of unborn children, threatened with a syphilitic heritage; and to recall that the loss of animal life involved in the work shrinks to insignificance beside that represented in any meat market you choose to pass, while the amount of animal suffering entailed might easily be duplicated in every one of a thousand fisheries, to whose activities the "humane" societies give never a thought.

IX. SYPHILIS AND ANTIVIVISECTION

The importance of a consideration of syphilis in arriving at any conclusion as to the justification of animal experimentation has, I think, been made sufficiently clear. But a word should be said about the light thrown on one or two of the stock objections to animal experimentation by a consideration of the experimental investigation of syphilis.

It is often asserted that research should be so controlled and limited that only those lines of work could be followed which give reasonable promise of practical result; and that the repetition of experiments solely for the purpose of confirming the work of others, should be made impossible. This sounds like a reasonable suggestion. Yet see how fatal such a policy would have been to the development of the knowledge of syphilis.

The whole remarkable success of Schaudinn came during a research undertaken to confirm the observations of another. Siegel[36] had reported the constant finding of an organism (*Cytorrhyctes luis*) in syphilitic lesions; and the Imperial Board of Health of Berlin appointed Schaudinn—a highly trained protozoölogist—to repeat the work and see if the observations could be substantiated. Siegel's findings were not confirmed, but during the investigation, the real cause of syphilis was unearthed.

Again, who could possibly have prophesied that Ehrlich's early interest in the chemistry of the dyestuffs would lead to contributions to the therapeutics of syphilis? If it was to have any valuable results, one would have expected them in the industrial arts. Yet, starting with chemistry, he then turns his attention to protozoan disease, founds the new science of chemotherapy, hears of the work of Schaudinn and Bertarelli, becomes interested in syphilis and ends by making an important contribution to its therapeutics. One is reminded of the career of Pasteur, who began in physics, with the study of crystallography, was led into an investigation of the wine and silk industries, founded the science of bacteriology and made a contribution to therapeutics of the first importance.

Indeed the work of the various students of syphilis has been so intertwined, and the results of one of so much value to the others, that in an account of any one research most of the prominent names appear and reappear. Schaudinn, Ehrlich, Metchnikoff and Roux, Siegel, Bertarelli—it was the constant familiarity of each of these with the work of the others, and the constant attempts to confirm and advance the results already obtained, that led to the marvelous progress made. Even so remote an event as the discovery of the coal-tars, years before, by Perkins, contributed to the result; for it made not only bacteriology, but also chemotherapy possible.

It is this interdependence of research and the property of discoveries to have the most remote and unexpected value that makes restriction to experimentation, based on the probable importance of its results, unwise. Those who have become familiar with the subject by actual work in the laboratories, feel that to add to the already great difficulties of experimentation, by surrounding it with petty restrictions, would be to reward medicine for her fine achievements by crippling her, to equip her for future tasks by veiling her eyes. For it must be remembered that it is after all to medicine, and not to the "humane" societies, that the public looks for relief from disease: and when your "humane" legislation has forced your scientist into exile if he is to continue his work of enlightenment (this is how Great Britain "encouraged" Lister!), *who is to accept the high* responsibility for increasing efficiency in the treatment of disease demanded by the suffering patients who will continue to crowd the hospitals? Will the "humane" societies, after making it a misdemeanor for a scientist to operate on an etherized dog without running to them for a permit, undertake to furnish us, in some other way than by experimentation, with the sorely needed facts about cancer and other unconquered plagues? Or should this work be entirely entrusted to those who have proved their fitness by their achievements in the study of syphilis?

---

[36] Siegel: München. med. Wchnschr., 1905, p. 1321.

It is high time that some protest was made against the cowardly charge that animal experimentation brutalizes men; and time, too, that those who launch it ceased to attain thereby a reputation for high moral sense in the community. The facts in the case are readily accessible; and if the charge is made in good faith, it ought to be backed by a notorious evidence of brutality in the profession which authorizes, and is in sympathy with, this "brutalizing" work. But whatever else physicians, as a class, are, brutal they most decidedly are not. Medicine can point to a group of heroes, not to be surpassed in any profession, who have testified to the sincerity of their scientific zeal by offering their own bodies as material for experiment; and until the opponents of animal investigation can match this, charges of brutality come from them with very bad grace indeed. Moreover, it is a simple fact that the physicians of any community —devoting their lives to the relief of distress—maintain a reputation for interest in others to which the term "brutal" is simply not applicable; and that in communities where experimentation is going on it is to those interested in animal investigation that the profession looks for leadership in its far-sighted campaign for the health and happiness of this and future generations. The reputation of these leaders, so far as brutality is concerned, is above reproach. The high standard of Pasteur, most kind-hearted of men, most active of experimentalists—has been maintained by his successors; and those who, in their righteous indignation, echo the outcry against experimentation on the ground of its brutalizing effect, might better serve the cause of righteousness by an inquiry, among the scientists in their own community, into the truth of this serious accusation.

If, however, this charge—so far from being made in good faith and on the basis of actual instances of brutalization of character by experiment—represents, for all its odor of piety, merely an academic makeshift for the purposes of debate, then one can but marvel at the moral standard of those who, in their concern over animals, permit themselves to make against a profession, busy with intelligent philanthropy, a charge so grave and so unjust.

CONVENIENT TABLE IN THE USE OF TUBERCULINS

GEORGE H. KRESS, M.D.

LOS ANGELES

The revival and wide use of tuberculin in the last few years has led a comparatively large number of makers of biologic products to place the different kinds of tuberculin in most common use on the market. As made by several of these firms, preparations like T. R. and B. E., presumably of the same strength, *really contain a different amount of the tubercle solids in the concentrated solutions.*

SYSTEM OF NUMBERING DILUTIONS OF TUBERCULIN *

No. of Dilutions	Strength Per Cent.	Compartment A		Compartment C		Compartment D		Compartment E		Compartment F	
		Fld. mg. in 1 c.c. conc. sol.	Fld. mg. in 0.1 c.c. conc. sol.	Solid mg. in 1 c.c. if 10 mg. to 1 c.c. conc. sol.	Solid mg. in 0.1 c.c if 10 mg. to 1 c.c. conc. sol.	Solid mg. in 1 c.c. if 5 mg. to 1 c.c. conc. sol.	Solid mg. in 0.1 c.c. if 5 mg. to 1 c.c. conc. sol.	Solid mg. in 1 c.c. if 2 mg. to 1 c.c. conc. sol. I (orig.)	100.	1000.	100.	10.	1.	5.	.5	2.	.2	1.	.1
II	10.	100.	10.	1.	.1	.5	.05	.2	.02	.1	.01
III	1.	10.	1.	.1	.01	.05	005	.02	002	.01	.001
IV	.1	1.	.1	.01	.001	.005	.0005	.002	.0002	.001	.0001
V	.01	.1	.01	.001	.0001	.0005	.00005	.0002	.00002	.0001	.00001
VI	.001	.01	.001	.0001	.00001	.00005	.000005	.00002	.000002	.00001	.000001
VII	.0001	.001	.0001	.00001	.000001	.000005	.0000005	.000002	.0000002	.000001	.0000001

* Old Tuberculin contains 1,000 mg. of Old Tuberculin to 1 c.c. Conc. O. T. (Compartment A, 1,000 mg.).

Von Ruck's T. R. contains 10 mg. of tubercle bacilli to 1 c.c. Conc. T. R. (Compartment C, 10 mg.).

Cutter's B. E. contains 5 mg. of dried tubercle bacilli to 1 c.c. Conc. B. E. (Compartment D, 5 mg.).

Cutter's and Mulford's T. R. contain 2 mg. of solid substance to 1 c.c. Conc. T. R. (Compartment E, 2 mg.).

Parke, Davis & Co.'s T. R. and B. E. each contain 1 mg. of tubercle bacilli to 1 c.c. of Conc. T. R. or B. E. (Compartment F, 1 mg.).

Von Ruck's Watery Extract contains 1 mg. of dry solids to 1 c.c. Conc. W. E. (Compartment F, 1 mg.).

In reading reports concerning patients under treatment, therefore, the dosage mentioned may be actually quite different from that which the reader has in mind *from the figures given.* As a rule, these firms also use *different systems of nomenclature in numbering their dilutions.* As a consequence physicians in the West not infrequently have patients referred to them with letters concerning the dosage of tuberculin previously used, the exact meaning of which dosage it is not always easy to understand.

The table above, which I use in dispensary and hospital work, *may be worth printing because,* if desired, they allow notations of the dose to be made in small space on the history cards and allow one at any time to estimate at a glance the exact amount of tubercle solids in milligrams which is contained in the dose of any dilution injected.

Starting with the original or concentrated solution, which in this system of numbering always receives the Roman digit I, the dilutions, made as is the custom, according to the metric system, are carried to as great a degree as is desired, each dilution being ten times stronger than the dilution below it, so that 10/10 of a c.c. of any dilution is equal to 1/10 c.c. of the dilution just above.

When these tables are used, the bottles containing the dilutions are labeled with the Roman numerals I, II, III, IV, etc., and in making notations of dosage on the history cards, this number is used as the denominator. The numerator is an Arabic numeral 1, 2, 3, 4, 5, 6, 7, etc., to represent 1/10, 2/10, 3/10, 4/10, etc., of a c.c. of that particular dilution.

Thus, 3/IV O. T. would mean 3/10 c.c. of dilution IV of old tuberculin, which, as may be readily seen by reference to Compartment A of the table below, implies a content of 3/10 milligrams of old tuberculin. Likewise 3/IV T. R., if made by Parke, Davis and Company (see Compartment F), would mean 3/10,000 mg.; while 3/IV T. R. of Cutter's make (see Compartment E) would mean 3/5,000 mg.; and of Von Ruck's T. R. (see Compartment C) would mean 3/1,000 mg. The name of the maker of the tuberculin is, of course, always mentioned on the history card.

The use of some such system of numbering as this can effect, therefore, a considerable saving of time when tuberculins are used with any frequency, and may also be of convenience to those who have need from time to time to calculate the exact dosage of some tuberculin only occasionally used, or in the more accurate interpretation of dosage figures given by colleagues elsewhere.

240 Bradbury Building.

THE FORMATION AND FUNCTIONS OF HYGIENE COMMITTEES FOR UNIVERSITIES

MAZYCK P. RAVENEL, M.D.
Professor of Bacteriology, Director of Hygienic Laboratory and Chairman Committee on Hygiene
AND
WILLIAM DODGE FROST
Associate Professor of Bacteriology, University of Wisconsin
MADISON, WIS.

The position of a university or any other large educational institution in regard to its students is a peculiar one, involving grave responsibilities of many kinds. Boys and girls are brought from their homes from greater or lesser distances, and perhaps for the first time in their lives are freed from the restraining influences of home life. These students collect in various dormitories or lodging houses and mix together on the campus, in class rooms, and in various assemblages incident to university life. The responsibility of the institution is, therefore, an exceedingly grave one. It takes the place of the parent or guardian to this mass of students. The danger of epidemic diseases, which is always present when numbers of people are brought together, is constantly present. That institution which looks only to the education of the mind through the completion of a fixed course of study falls very far short of its true functions. Those of us who are interested in the teaching of hygienic life see in every educational institution a golden opportunity to spread the doctrine of good living. Education, after all, is designed to fit one for a useful career in life and such a career demands first and foremost a vigorous and healthy body.

Most of our institutions, like Topsy, have "just growed." The old buildings which are objects of reverence and affection to many were built at a time when our youth perhaps possessed more vigorous constitutions than those which the present-day fast living has brought about, and when the principles of lighting and ventilation were not as well understood as now. Partly through reverence and partly through the necessities of the case, almost all institutions are still utilizing many of these old buildings, and large classes are held in rooms absolutely unfit to furnish suitable accommodations.

HISTORY OF THE HYGIENIC MOVEMENT AT THE UNIVERSITY OF WISCONSIN

A history of the movement for better things in health matters at the University of Wisconsin will serve to elucidate many of the considerations which we wish to bring before you. Although the university is still comparatively in its youth, having recently celebrated its fiftieth anniversary, many of the buildings are antiquated as regards hygiene. A few years ago, several of the professors, recognizing that there was no one connected with the university whose special duty it was to look after the sanitation of the buildings and the health of the students, asked the president to appoint a committee on university hygiene. The first committee was composed of representatives from the departments of bacteriology and hygiene, physiology, physical training and home economics. The work was developed along several lines.

Ventilation.—First, an attempt was made to secure better conditions in the class-rooms and offices. Where artificial means of ventilation were not provided the windows were fitted with window-boards which permitted the raising of the lower sash without producing direct draughts on the occupants of the rooms. In most of the buildings a combined system of ventilation and heating had been installed. Direct radiation from the steam radiators was supplemented by passing air over steam coils by means of fans and blowing this into the rooms through galvanized iron channels. This apparatus was used for the most part only in extremely cold weather. When the weather was not cold enough to require the use of both systems no artificial ventilation was given at all. The committee insisted that the fans should be used for ventilation and not merely to supplement the heating of the rooms. This improved matters considerably, but still many complaints came in to the committee from professors and students alike that the rooms were stuffy and close, causing headache and sleepiness.

Humidity.—A study of the humidity of the air in a number of these rooms was next undertaken, and it was found that the moisture was frequently as low as 20 per cent. and some times as low as 14. The moistening of the air was brought about by the introduction of steam jets into the ventilating flues at or near the fan, so that the moisture would be thoroughly mixed with the air passing into the rooms. Examination of these rooms after this showed that the air was fairly well moistened and the comfort of the occupants of the room was greatly increased. Several of the professors who had used these rooms for ten or more years stated that never in their experience had they lectured with so little fatigue and discomfort. The committee has several times asked for funds to make more complete studies of the air of class rooms, but it has not been able to procure them up to the present time.

It is not believed that conditions at Wisconsin were worse than those at many other institutions, and yet the actual state of affairs was represented by the following incident. The matron of the woman's dormitory went into the room of one of the girls and, noticing the bad air, called the girl's attention to it, and received this reply: "What, is the air bad here? Since coming to the university I have become so used to bad air that I do not notice it any more."

Water.—The university had a pure water-supply, but everywhere the common drinking-cup was in evidence, some installed in the early days of the university, but some quite recently. The committee succeeded in having all of these drinking-cups abolished and in their place sanitary drinking fountains (Fig. 1) have been installed. These fountains were devised at the university and made by the mechanics connected with the institution. The cost was estimated at $5 each.

Sweeping.—A third matter to be considered was the cleansing of the buildings. Dry sweeping and dusting were the usual customs. In several of the buildings the committee succeeded in having vacuum cleaners introduced. In two buildings permanent systems have been introduced, and in two, portable machines are being tried out. In selecting a type of vacuum-cleaner, the committee found that while there was evidently a good deal of difference in the relative cleansing power of the machines, there was no described method of testing them. Some members of the committee have undertaken a study of this problem, the results of which are about ready for publication. In anticipation, however, it may be said that, while the permanent systems vary in their ability to clean, they are all satisfactory from a hygienic standpoint; that the portable cleaners are all, so far as tested, less efficient in their cleaning power, and that they all have an insanitary feature of very considerable importance, namely, the discharge of a large number of bacteria into the air again. Such machines, instead of reducing the danger from air-borne germs, may actually increase it.

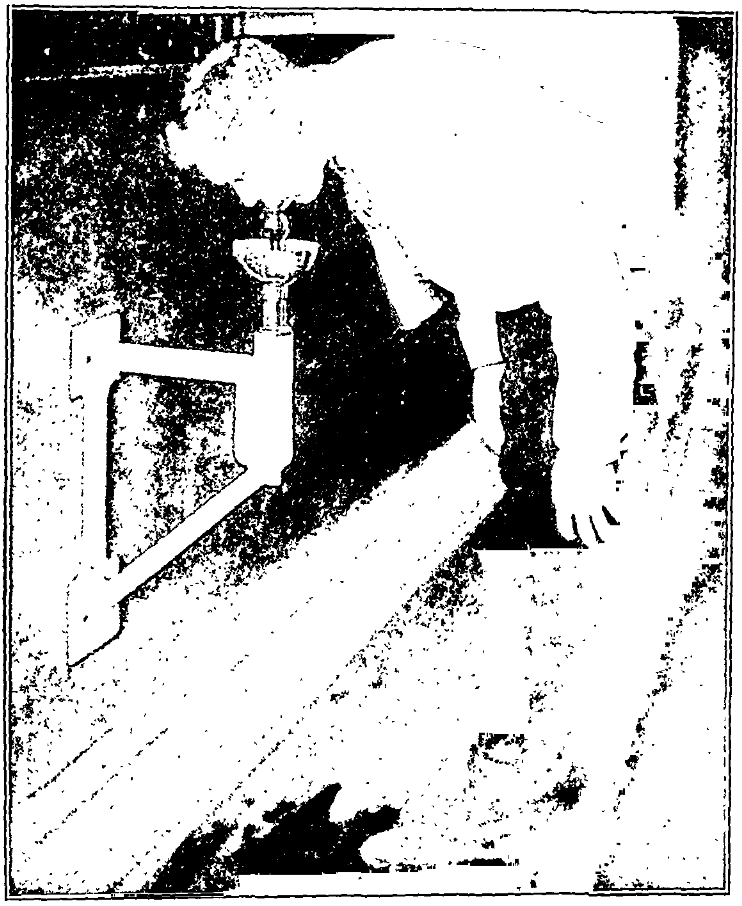

Fig. 1.—Sanitary bubble drinking fountain.

Toilets.—The toilet rooms of the university have been objects of especial care. Where possible, ventilators have been put into these, but unfortunately change in such facilities often involves a heavy expense and in most instances it has been impossible so far to make any radical changes. The supervision exercised has, however, improved matters considerably. The roller towel has been banished from the university almost entirely and in its place individual towels are provided. A special towel-holder and soiled towel box in one, so arranged that the top towel of the pile may be used and then passed over a curved rod into the compartment for soiled towels (Figs. 2 and 3) has been installed throughout the university. It is the device of three members of the committee and has served an excellent purpose. There is some increase in the expense of laundry, but we feel that this is money well spent. As an example of some of the difficulties which such a committee has to contend with at times we may relate that in one department of the university the dean objected to the increased laundry expense, slight though it was, and, without consulting the committee or any one else, had these small hand-towels sewed together into roller towels.

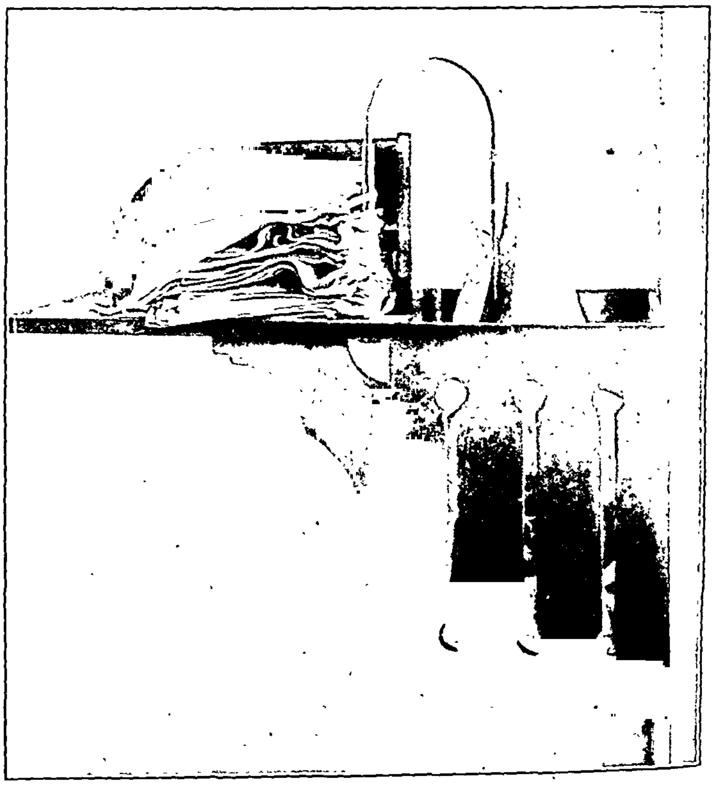

Fig. 2.—Individual towel distributor.

Gymnasium.—At the University of Wisconsin physical training is compulsory during the first two years of student life. Consequently the university gymnasium is likely to become an important focus for the distribution of disease; but if properly managed it may serve as a valuable center of educational influence along sanitary lines. The committee went vigorously to work at this building. Spitting was common, some of the instructors even believing that it was necessary to spit during exercise. Members of the committee attended all indoor games and kept watch on the careless spitting of the players. In two years' time this habit has been entirely stopped and it is a very rare occurrence to see anyone spit about the gymnasium, or to find the marks of expectoration on the floors. Under the influence of the committee the gymnasium has been cleaned from top to bottom, new mats have been provided, varnish and whitewash applied, and very important changes made in the toilet-rooms. Formerly any slight wound in the gymnasium meant suppuration and slow healing. This condition of things has greatly improved. Every student was formerly familiar with what is generally known as "gym itch" and "gym sores." While these still exist to a certain extent, conditions have improved. The committee has made a number of analyses of the water in the swimming-pools, both chemical and bacteriologic, and the hygienic laboratory is now preparing to publish the result of these examinations.

Lodging-House Inspection.—Wisconsin has no dormitory system (with the exception of one building for girls, which does not lodge more than one-tenth of the total number). The students are therefore domiciled at private rooming and boarding houses in various parts of the city. The Greek-letter fraternities and sororities flourish, and there are upward of thirty lodges in the town. The university regents, on the request of the committee, have for two years past granted money for the inspection of student boarding and rooming houses. A trained nurse is employed, one hundred and seventy houses have been inspected and a record made of them. A few houses have refused to allow inspection, but as a rule the landlords and landladies have cooperated with the committee in trying to improve the standard. It is proposed to make from one to two inspections yearly and to provide students with lists of the accredited houses; that is, those houses which have such qualifications in regard to lighting, ventilation, heating, bathing and toilet facilities as render them desirable habitations.

Medical Adviser.—The university had never made provision for a medical adviser for the students. When a student was sick he went to one of the physicians in the city, or not, as he saw fit. There was no system even of keeping a record of illnesses. Cases of small-pox have appeared in the class-rooms and in 1908 a severe outbreak of typhoid fever (forty-one cases in one boarding-house) occurred which would probably have been prevented had proper medical supervision, free of charge, been provided. Excuses were granted for nonattendance at classes, etc., by physicians who had no concern with the university. The committee spent a great deal of time in trying to evolve some plan for the correction of this evil and finally recommended to the president the appointment of a medical adviser. This proposition was considered favorably by the board of regents and the matter was then put into the hands of the executive committee of the medical school. Several of its members were also members of the hygienic committee. In February, 1910, an office was opened and it was not long in proving very popular with the students. In less than one year the staff has been enlarged from one physician to three, with three assistants, two of whom are trained nurses. We believe that much epidemic sickness of a minor character has been avoided by consultation with the university physician, who insists on isolation in such cases. More than 3,000 students have consulted the medical adviser during the year 1910.

Emergency Kits.—Accidents of greater or less severity not infrequently happen in the laboratories of the university, especially in chemistry and engineering. Emergency kits, designed by the committee, have been placed throughout the university. They contain absorbent cotton, assorted bandages, a tourniquet, adhesive plaster, safety pins, carron oil, boracic acid ointment and aromatic spirits of ammonia. Each article is plainly labeled. Those on the drugs give the indications for use and the dosage. Charts giving directions for first aid to the injured have also been distributed. Those obtainable have not been satisfactory and the committee is now taking steps to obtain better ones which will be distributed.

Education.—Apart from the practical work which has been outlined, the committee has been strongly impressed with the necessity of educating students along hygienic lines. It has tried in every way to give and to foster instruction in the principles of hygiene. The department of bacteriology and hygiene has for some time wished to make a primary course in hygiene compulsory on all students entering the university. The committee has aided the department as far as possible in this work. Up to the present time it has seemed impossible to require work from each student in the university, but both the department and the committee are impressed with the necessity of this and are working toward such an end. In the meantime an elective course has been offered. This is primary in character and no preliminary studies are required. It consists of eighteen lectures with assigned reading and an examination, for which one hour of credit is given. This course is repeated in each semester of the scholastic year. The lectures are given almost entirely by men connected with the university, especially those in the departments of physiology, physical training, bacteriology and hygiene and chemistry. At the request of the committee the regents have for several years granted a fund of $300 for lectures. The object of these lectures is to bring to the university men prominent in sanitary work, hoping thereby to interest the professors as well as the students in the study of hygiene, and to convince them of its importance and its practical value.

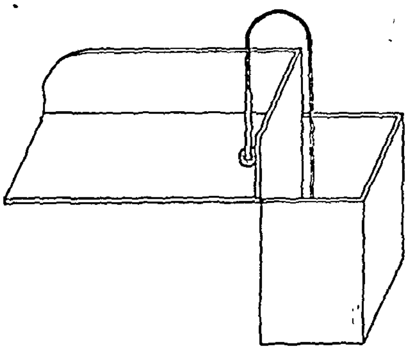

Fig. 3.—Drawing of towel distributor.

MEANS AND METHODS OF HYGIENIC IMPROVEMENT

Institutions of high learning should have their buildings perfectly equipped from a sanitary standpoint. Many institutions, in which technical departments exist, have model machine shops, creameries, cow-stables, libraries, etc. They are leaders in these various lines. Schools, colleges and universities ought to lead in sanitary construction, sanitary equipment, and sanitary care. Class-rooms and laboratories ought to be models of sanitary excellence as well as of convenience and attractiveness. The educational value of such buildings far outweighs any additional expense involved.

Exhibits.—In connection with the educational work which can be done along the line of hygiene, mention ought to be made of the value of exhibits, museums, etc. Collections of models and plans are excellent means of public education. Permanent museums of hygiene are desirable, not only as an aid to class work, but for the instruction of the general public, and it would seem desirable that various sanitary appliances might be exhibited where the public could study them. Such into the room of one of the girls and, noticing the bad air, called the girl's attention to it, and received this reply: "What, is the air bad here? Since coming to the university I have become so used to bad air that I do not notice it any more."

Water.—The university had a pure water-supply, but everywhere the common drinking-cup was in evidence, some installed in the early days of the university, but some quite recently. The committee succeeded in having all of these drinking-cups abolished and in their place sanitary drinking fountains (Fig. 1) have been installed. These fountains were devised at the university and made by the mechanics connected with the institution. The cost was estimated at $5 each.

Sweeping.—A third matter to be considered was the cleansing of the buildings. Dry sweeping and dusting were the usual customs. In several of the buildings the committee succeeded in having vacuum cleaners introduced. In two buildings permanent systems have been introduced, and in two, portable machines are being tried out. In selecting a type of vacuum-cleaner, the committee found that while there was evidently a good deal of difference in the relative cleansing power of the machines, there was no described method of testing them. Some members of the committee have undertaken a study of this problem, the results of which are about ready for publication. In anticipation, however, it may be said that, while the permanent systems vary in their ability to clean, they are all satisfactory from a hygienic standpoint; that the portable cleaners are all, so far as tested, less efficient in their cleaning power, and that they all have an insanitary feature of very considerable importance, namely, the discharge of a large number of bacteria into the air again. Such machines, instead of reducing the danger from air-borne germs, may actually increase it.

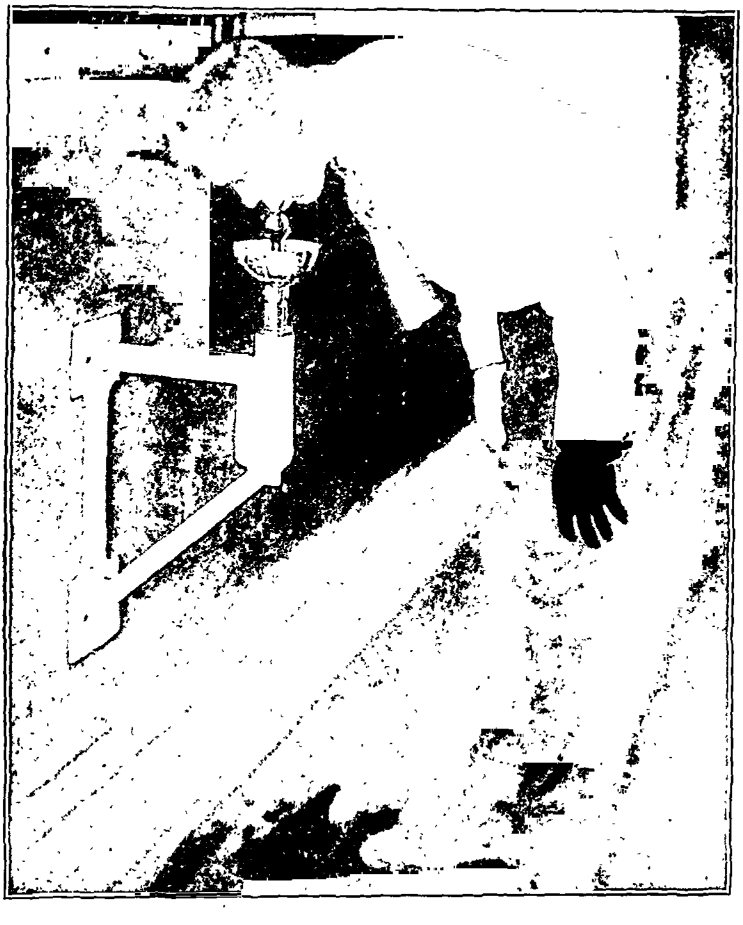

Fig. 1.—Sanitary bubble drinking fountain.

Toilets.—The toilet rooms of the university have been objects of especial care. Where possible, ventilators have been put into these, but unfortunately change in such facilities often involves a heavy expense and in most instances it has been impossible so far to make any radical changes. The supervision exercised has, however, improved matters considerably. The roller towel has been banished from the university almost entirely and in its place individual towels are provided. A special towel-holder and soiled towel box in one, so arranged that the top towel of the pile may be used and then passed over a curved rod into the compartment for soiled towels (Figs. 2 and 3) has been installed throughout the university. It is the device of three members of the committee and has served an excellent purpose. There is some increase in the expense of laundry, but we feel that this is money well spent. As an example of some of the difficulties which such a committee has to contend with at times we may relate that in one department of the university the dean objected to the increased laundry expense, slight though it was, and, without consulting the committee or any one else, had these small hand-towels sewed together into roller towels.

The educational value of such buildings far outweighs any additional expense involved.

Exhibits.—In connection with the educational work which can be done along the line of hygiene, mention ought to be made of the value of exhibits, museums, etc. Collections of models and plans are excellent means of public education. Permanent museums of hygiene are desirable, not only as an aid to class work, but for the instruction of the general public, and it would seem desirable that various sanitary appliances might be exhibited where the public could study them. Such arations from ulcers on exposed parts of several months' duration should be carefully examined for the presence of the pathogenic agent of Oriental sore (*Leishmania tropica*). A preliminary experience with the cultural forms of trypanosomes or with insect flagellates—*Herpetomonas* or *Crithidia*—is helpful in knowing what to search for when the microorganisms are sparse.

Specific diagnosis is important because the infection is undoubtedly transmitted by flies or mosquitoes and the ulcers should be properly treated and protected by dressings from the visits of suctorial invertebrates.

The case reported here is the third one found to date and illustrates certain peculiar features of the disease: the chronic eroding character of the ulcer, its location on an exposed part, the presence of a second ulcer near by (auto-inoculation), the history of a fly-bite, and the difficulty experienced in this case in finding the pathogenic agent.

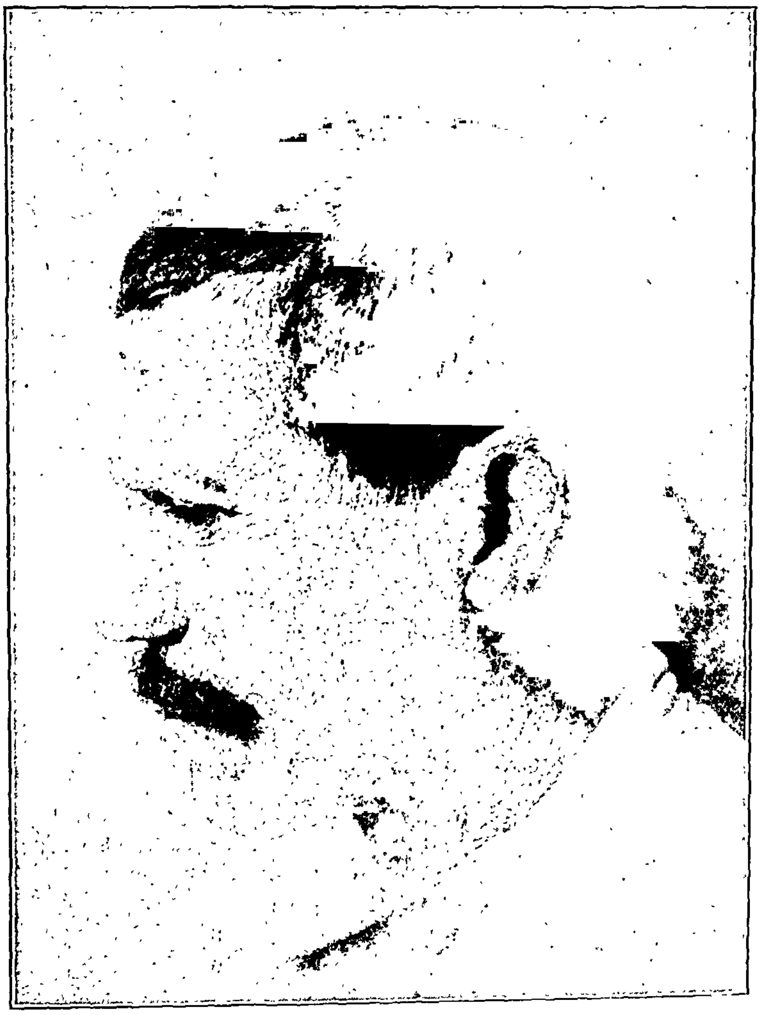

Fig. 1.—Patient with oriental sore on left ear.

It should be mentioned that each one of the three patients affected with this disorder who have been examined up to date gave a history of being bitten by a fly out in the bush. No case has arisen as yet within the zone of sanitation.

CASE REPORT

History.—A. V., Hospital Number 88,593; aged 43; native Colombian laborer; born in Cartagena, came to Panama during the régime of the Compagnie universelle du Canal interocéanique, and has lived continuously in Panama for twenty-two years. Recently he had been working with surveying parties in the bush near Frijoles. He was admitted Nov. 25, 1910, with well-developed pulmonary tuberculosis. The peculiar lesions on his left ear were examined on two occasions for the presence of *L. tropica* and on the occasion of the second examination after a crust had been permitted to form, a few characteristic microorganisms were detected.

Examination.—When seen December 21, his left ear was of a dusky, brawny color, somewhat swollen, and the skin rather tense. The margin of the helix was eroded for about 3 to 4 cm. and covered with a depressed, tough, dry crust. At its junction with the lobule there was a second smaller ulcer, circular in shape, about 1.5 cm. in diameter, covered with a flattened tough crust (auto-inoculation). The appearance of the ulcers was suggestive of lupus or rodent ulcer and of Oriental sore. A protective dressing of boracic acid ointment was applied constantly and some improvement in the appearance of the lesions was noted, but the infiltration of the margin of the skin about the ulcers increased. The patient refused more radical treatment on account of his feeble health.

The larger ulcer made its appearance, according to the patient, six or eight months before the date of his admission to the hospital. He believed that it followed a fly-bite, but on inquiry about the variety of fly and additional circumstances connected with the development of the sore, rather a fanciful statement was made by the patient. This is given as it conveys the natives' notion about the cause of this chronic type of skin ulceration.

The fly which the natives believe causes the ulceration is called by them *mosca bayano*. This fly, they say, is found only in the woods in the large yellow flowers of the bayano, a jungle plant. It was impossible to get from the patient a very exact idea of the kind of fly. When shown a number of specimens of *Tabanus, Musca, Stomoxys, Pyrellia, Compsomyia,* and others, he thought the fly was about the size of *Stomoxys calcitrans*, but when he described its habits he said that on approach, the flies darted away so quickly that one could not make out either color or markings. Again the patient said that the fly did not really bite or draw blood, but deposited white feces which made the skin rot.

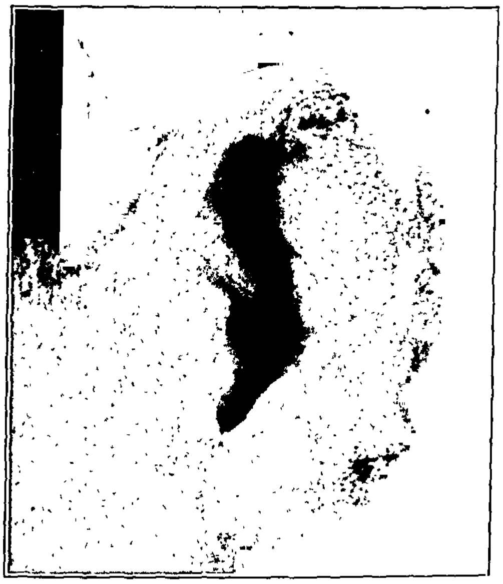

Fig. 2.—Closer view of oriental sore.

After the visit of the fly the place began to itch, a blister formed, which was scratched considerably, increased in size and became purulent. An ulcer soon appeared, which, with each removal of the scab, became deeper and larger.

Whatever the mode of infection may have been, there is no doubt of the cause: smears taken from just beneath the raised margin of the crust, when stained by Hastings' and Giemsa's stains, contained a few intracellular and extracellular specimens of *L. tropica*, exactly like those described in the case to be published by one of us (S. T. D.) in the *Archives of Internal Medicine.*

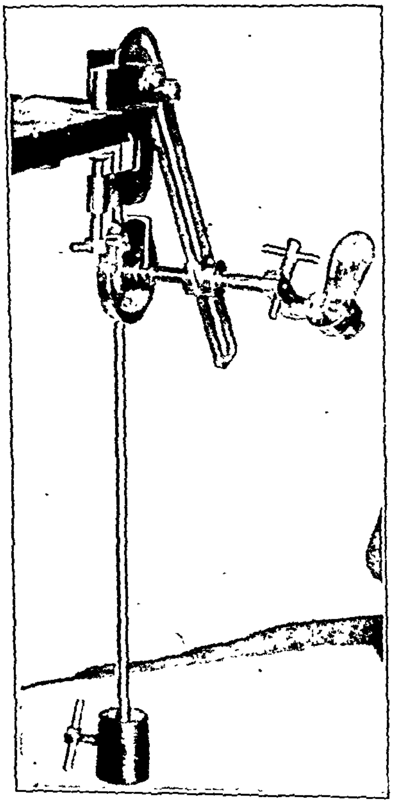
Regulation of Diet.—An ideal diet should be one with not less than 1,500 calories in the twenty-four hours, containing the foodstuffs in as assimilable a form as possible, entailing the least work on the eliminative organs in ridding the body of waste products.—A. Eustis, in *New Orleans Medical and Surgical Journal.*

MINIATURE EXERCISE MACHINE FOR INFANTILE PARALYSIS *

MAX STRUNSKY, M.D.
NEW YORK

In treating chronic infantile paralysis by massage, electricity and passive motion of the paretic muscles we must not forget that the seat of the disease is not in the muscles, but in the anterior, gray cornu of the spinal cord, and that atrophy and degeneration in this disease are not limited to the muscles alone, but involve all the structures that enter into the muscular contraction, chiefly, the spinal nerves, the motor cells in the spinal cord, the conducting tracts, the motor brain centers dominating the affected muscles, as well as the weakening of the will power to concentrate on these muscles.

Function is the antagonist of atrophy and degeneration. Massage, electricity and passive motion exercise the muscles, but they do not exercise the other structures involved in the voluntary muscular contraction, and the effect of such exercise — whatever it may be—is limited to the muscles. Permanent benefit to the paralytic muscles is produced only by voluntary exercise because in such exercise the structures involved are simultaneously and cooperatively functioned. The effect of voluntary muscular contraction is to exercise the will power and the atrophic motor brain centers and, by reciprocal action, to develop the motor cells in the spinal cord and the strength of the muscles.



Miniature Zander machine for exercising limb in infantile paralysis. May be attached to a table or chair.

That the spinal motor power can be developed is proved by the improvement that takes place in infantile paralysis often years after the original attack, and by the increased strength in the paralytic limb after scientific and persistent treatment, and by the fact that a great many children, especially those that are mildly affected, gradually outgrow their trouble.

Improvement in chronic infantile paralysis cannot be accounted for by the regeneration of the destroyed motor cells in the spinal cord. The pathologic law that dead organic cells never regenerate is fixed. Improvement can be explained only by the development of the motor gray matter in the spinal cord based on the physiologic law that cells increase in size and strength with function. This is accomplished by the use of the paralytic limb, by muscle education, whereby the child develops his mental power to force the contraction of the paretic muscles, and by the natural growth and evolution of the cerebrospinal system during childhood.

Voluntary exercise of the paretic muscles, the most important element in the treatment of chronic infantile paralysis, is, unfortunately, monotonous and the child's feeble attention soon wanders from its work. The machine illustrated gives the child something to do, with the result that more voluntary muscular contractions are accomplished. The machine is also labor-saving, inasmuch as it assists and resists the movements of the paralytic limbs automatically and takes away this strain from the person supervising the physical culture.

The instrument shown in the illustration is a miniature Zander machine. It is small, portable, cheap, and can be attached to a table or chair. The child sits on the table or chair to which the machine is attached and the paralyzed limb swings the handle. The resistance to the movement is regulated by the length of the pendulum and the "assistance" by the angle of the handle.

Resistance to the movements must be gradually increased. This cannot be done with the hand, because it is hard to remember the exact force exerted at the previous treatment. By regulating the length of the pendulum the resistant force is controlled to a fraction. The gradually increased length in the pendulum is also the record which tells of the amount of improvement that has taken place in the paralytic limb in a given time.

THE TRANSPLANTATION OF BONE FOR CORRECTION OF DEPRESSED DEFORMITIES OF THE NOSE

REPORT OF CASES *

WILLIAM WESLEY CARTER, A.M., M.D.
Assistant Surgeon, Manhattan Eye, Ear and Throat Hospital
NEW YORK

It is not my purpose in this paper to discuss the fundamental principles of bone transplantation in the human body, nor do I intend to review in detail the work of the various experimenters in this field of surgery. Suffice it to say that nearly all that has been written on this subject has had to do with supplying defects in the various bones of the body, chiefly those of the head and the long bones, while little has been said about the introduction of bone into the soft tissues, where the conditions for its nourishment and growth must differ widely from those where the graft is used to supply a deficiency in the continuity of another bone.

It is generally admitted (1) that the autoplastic operation, i. e., the transference of bone from one part of the body to another gives the quickest and best results; (2) that homoplastic transplantation, i. e., from one animal to another of the same species, is usually successful; (3) that heteroplastic transplantation, i. e., from one animal to another of a different species, is unsuccessful.

---

* Read before the New York Academy of Medicine, Section on Laryngology, Dec. 28, 1910.

The belief is almost unanimous that it is necessary to include the periosteum with the graft; with this view, however, I do not agree.

There are a variety of opinions as to the fate of the implanted bone, the majority of writers believing that it is resorbed and new bone deposited in its place by the periosteum. This however, so far as I know, is the observation of those who have done only the homoplastic operation and who removed the periosteum with the graft; their work, therefore, sheds little light on the ultimate fate of the bone in my cases, for each of my patients furnished his own tissue for transplantation, and no periosteum covered the graft. The observations of all these writers relate to implantation for defects in the various skeletal bones, and however interesting and pertinent they may be to the work in hand, the scope of the present paper does not admit of their discussion.

Depressed deformities of the nose, from a surgical point of view, may be divided into two classes: (1) cases without loss of bony tissue; (2) cases in which a large part of the bony framework of the nose has been destroyed.

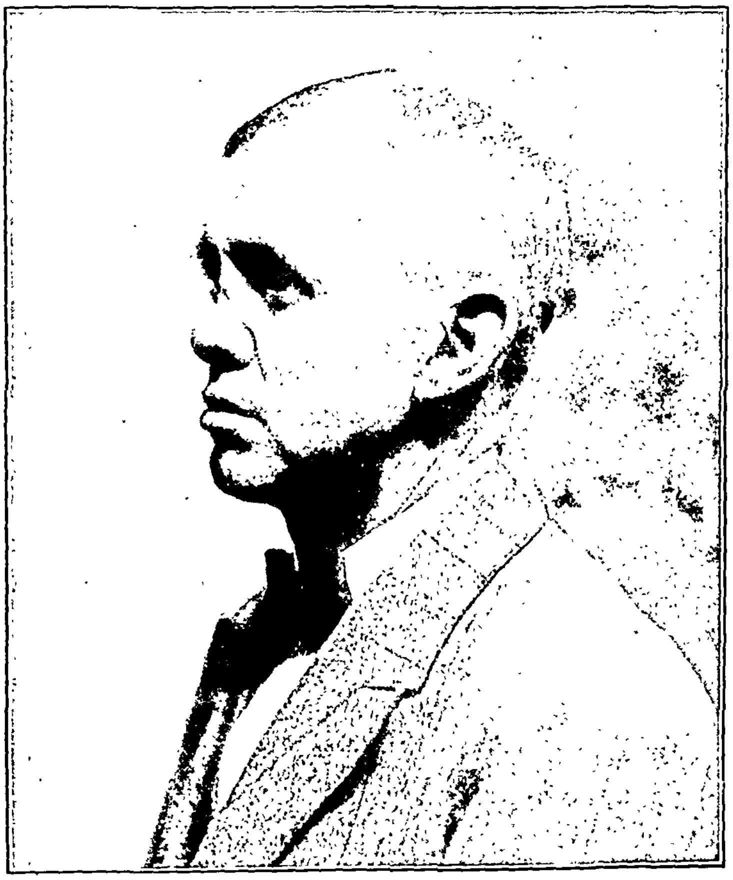

Fig. 1.—Patient in Case 3 before operation.

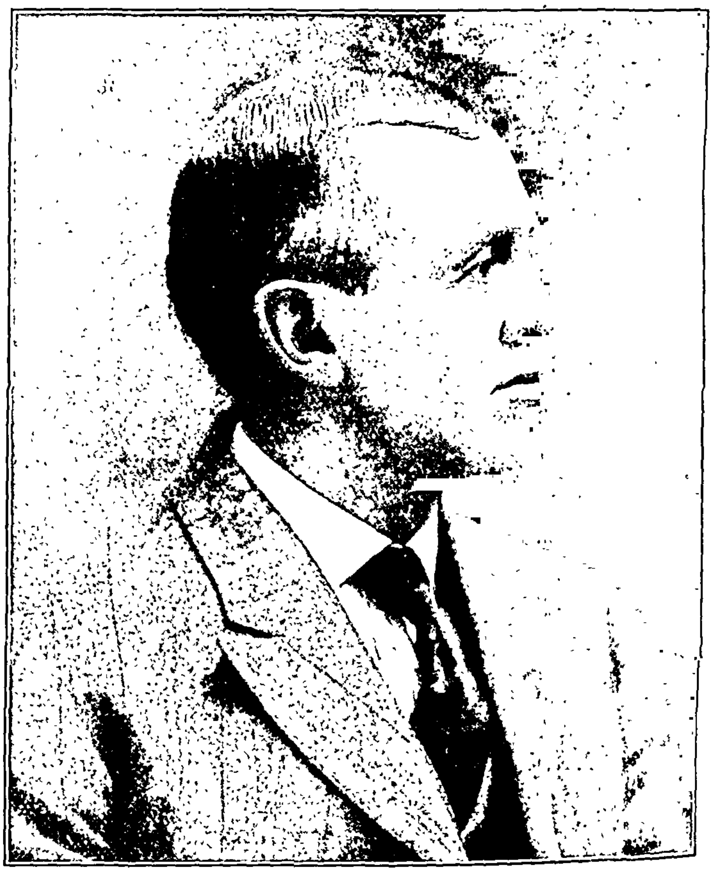

Fig. 2.—Patient in Case 3 after operation, from an unretouched photograph.

Cases of the first class are suitable for my bridge-splint operation, which I have described[1] in a previous paper, and which I have used with satisfaction in about forty cases.

But patients in the second class, as I stated in my first presentation of the subject, cannot be relieved by this method, for the success of the bridge-splint operation depends on the presence of a sufficient amount of bony tissue in the nose to retain it in the corrected position after the removal of the supporting bridge.

The cases which I report are from the clinic of Dr. Harmon Smith at the Manhattan Eye, Ear and Throat Hospital. Each patient had a depressed deformity due to traumatism, and each had suffered considerable loss of bony framework of the nose.

The deformity in each case being clearly due to the deficiency in bone, it occurred to me that this might be supplied by transposition of bone from another part of the body; my idea being that the transplanted tissue would receive only a temporary injury, and that it would continue to live and would take part in the process of repair in its new position in the nose.

I decided to use the rib for the following reasons:

1. A portion of the rib is easily removed, especially about the middle of the ninth rib, where the muscular covering is very thin. The patient is caused no inconvenience, and the resected portion is quickly reconstructed from the periosteum. This new growth of bone is hastened by the movements of the chest, for it has been found that a certain amount of irritation is favorable to bone-production. According to Ollier from three to eight months are required for the construction of a bone of considerable size, while he has known a metacarpal bone to be restored in forty days.

2. The shape and structure of the rib favor its use for this purpose. The rib is composed of cancellous tissue covered with a thin layer of compact bone. When the bone is split and the cancellous tissue removed, the strips of compact bone can be easily shaped to suit the deformity and, if the occasion demands it, several layers of this bone can be superimposed. It is necessary to remove the cancellous tissue, as this does not add to the vitality of the graft. In cases in which implantation has been made for defects in the long bones and the medullary tissue has not been removed, it has caused an irritation and aseptic fever.

Furthermore, I believe that the rib is well adapted for transplantation purposes, because it is so abundantly supplied with minute nutrient foramina. This can be easily demonstrated by examining the surface of a rib with a lens and comparing it with the tibia.

---

[1] Carter, William Wesley: The Correction of Depressed and Irregular Deformities of the Nose by Mechanical Replacement, The Journal A. M. A., Dec. 4, 1909, p. 1893.

My reasons for removing the periosteum from the grafts are: First, it is easier to resect a rib without injuring the pleura by shelling it out of its periosteal covering. Besides it is desirable to leave the periosteum for the reconstruction of the rib. In the second place, I believe that the bare bone is more quickly and surely nourished by the connective tissue envelope which quickly covers it when it is introduced into the soft tissues of the nose. In this location, all we want is sufficient nourishment for the implanted tissue, we have no desire to grow bone; hence we can dispense with the osteogenetic layer of the periosteum.

The operation in all three of my patients was essentially the same.

The skin over the nose and over the ninth rib on the right side is prepared for an aseptic operation; a short, transverse incision is made down to the bone at the nasofrontal suture. Through this incision the skin and subcutaneous tissues over the dorsum of the nose are elevated with a long, thin, two-edged knife, curved on the flat. (A Seiler septal knife answers the purpose very well.) Above this incision the tissues, including the periosteum, are elevated for about three-eighths of an inch. This wound is covered with sterile gauze. The ninth rib at about its middle is then exposed for two inches and shelled out of the periosteum and removed. I then split this section of rib in its transverse diameter, scrape off its medullary portion and shape one of the strips of bone to suit the deformity. This is then inserted into the wound in the nose previously made for its reception, care being taken to insert the upper end under the periosteum over the nasofrontal process. Both wounds are then irrigated with sterile salt solution, closed with silk sutures and sterile dressings applied. The dressings are changed for the first time on the seventh day and the sutures removed two days later.

CASE 1.—The patient was a little girl, aged 6, who, when 2 years old, fell on her nose, fracturing it. The nose retained its infantile type, developing broad and flat and scarcely protruding beyond the general level of the face. On examination, no nasal bones could be demonstrated. After the operation, which was performed on June 21, 1910, the profile was almost perfect and has remained so up to the present time.

CASE 2.—This patient, a woman, aged 25, fell on her nose when she was 7 years old, the injury in this case being followed by septal abscess. There is no history of specific infection, and the woman says that she has always enjoyed the best of health. The deformity was marked and was of the flattened and concave variety.

Operation was performed on June 25, 1910. In this instance two layers of bone grafts had to be superimposed. When the deformity had been completely corrected the tension on the skin was so great that it became blanched; so, fearing that sloughing might occur, I had to slip the transplanted bone up a little, which left a slight depression near the tip. The bridge, however, is completely reconstructed and the result is satisfactory. There has been no retrograde change in the profile up to the present time, seven months after the operation. The bone is firmly imbedded and interstitial union seems to have occurred between the two implanted fragments.

CASE 3.—A railroad man, aged 47, always healthy, and having no specific history, was knocked down by a train on Dec. 14, 1908. In addition to other severe injuries, his nose was almost completely destroyed (Fig. 1). The nasal bones, the nasal processes of the superior maxillæ and the septum were involved. Erysipelas followed the injury and much bony tissue sloughed out. The bridge was badly depressed and flattened, and a large scar bound the skin to the subjacent tissue. The septum was almost completely destroyed. The case presented a very unfavorable outlook for correction by any method of treatment.

Operation, which was done on Oct. 20, 1910, was somewhat tedious, owing to the large amount of scar tissue making it very difficult to elevate the skin over the dorsum of the nose, The elevated flap, too, was very thin, owing to the large destruction of skin at the time of the injury. A piece of the rib about 2 inches long was inserted, one end extending well down to the tip of the nose, and the other resting on the nasal process of the frontal bone. The normal coutour of the nose was immediately restored. The grafted bone acted as a rafter, being firmly supported by the nasofrontal process, and it continued to exert a gradual traction on the soft tissues of the nose, which, having been unsupported, had subsided into two folds on either side of the nose. Within two weeks these folds had completely disappeared, the tissue having been drawn up into its proper place in the nose. The result in this case was practically perfect (Fig. 2).

In none of these patients did the temperature rise above normal, and none complained of much discomfort after the operation. The recovery of all was uneventful, primary union of the wound being obtained in each instance.

The vitality of the bone seems to have been affected in no way, and it is my belief that it has taken part in the process of repair, being nourished by an envelope of connective tissue forming practically a new periosteum. Certainly none of the transplanted bone has as yet been absorbed, and I see no reason why it should be, since the transplanted tissue is not a foreign body but is a living part of the same body into which it is replaced. Its molecular constitution is exactly the same as that of the tissues that surround it in its new position. Therefore it will continue to live, provided that its circulation is reestablished from the surrounding tissues; a sufficient time has elapsed to make us feel reasonably certain that this has already occurred in all three of my cases.

I believe that a large proportion of what have been considered hopeless cases of nasal deformity may be relieved by this method of treatment. Its superiority over all methods involving the introduction of foreign bodies into the tissues is self-evident.

Black Plague in Newspaper Advertising.—It is encouraging to note from time to time in these columns the indications of an awakening conscience on the subject of truthful advertising. In an address at the one hundred and tenth dinner of the Sphinx Club, at the Waldorf-Astoria, New York City, James Schermerhorn, publisher of the Detroit (Mich.) *Times*, gave little comfort to newspaper men who sell advertising space to any one who has the price to pay for it. "It is a shabby trick," he said, "to capture the reader with editorials upholding the decencies of life only to deliver him over to the spoilers who lie in wait for him in the advertising section of the paper. There is a white plague, and philanthropists are fighting it. The publisher helps in his editorial and news columns. But in his business section there is a black plague, an inky infection in the form of spurious consumption remedies offering false hope to the hopeless; brazenly guaranteeing to cure the incurable. The awful cry of the despairing leper, 'Unclean! Unclean!' ought to be branded on the newspapers infected by the black plague. What of the publisher who entices his readers into wildcat investments by lifting the shell and showing the pea? Is he an opinion-holder or just a capper? The genuine brand of national righteousness should begin with the newspaper that advocates it. It is better to protect the reader every day against chicanery and betrayal than to use tainted money for the spectacular schemes for relief." Such public statements as these help to bring the day when there will be but one standard for right and wrong, and when there will be no privileged class that is permitted to lie and swindle with impunity.

POTASSIUM PERMANGANATE AS A HEMOSTATIC

L. BUCKLE, M.D.
NEW YORK

History.—A new-born baby boy, Jewish, weighed 9 pounds, had good color, nursed well and looked healthy up to the eighth day. No history of hemophilia. When the cord was tied and divided immediately after birth, there was no unusual bleeding and on the sixth day it came off.

Hemorrhage.—On the eighth day, about noon, the boy was circumcised and bandaged. Two or three hours later, the nurse noticed that the bandage and parts of the diaper were saturated with blood. She called me, and, finding the oozing very slight, I ordered gauze saturated with hydrogen dioxid to be applied to the bleeding surface. This I had found adequate to control hemorrhage in apparently similar cases. About 7 p. m., I was again called. The bleeding had not ceased, though the oozing was just as slight as before. I applied styptic cotton, adrenalin 1 to 1,000, powdered alum, tannic acid, and solution of silver nitrate, at different times, but without result. The family became so anxious and excited that they took the child to the hospital. There the skin was stitched to the mucous membrane above the glans, in the hope that this would help to check the bleeding; but it did not. In the two days the baby was in the hospital, it grew so pale and weak from the loss of blood that the father, not getting much assurance from the surgeons of its recovery, took it "to die at home," as he said.

Application of Potassium Permanganate.—On the fourth day after the circumcision I was called hurriedly. The baby was extremely pale and very feeble. It could not nurse from the breast but when some milk was pressed from the nipple into its mouth it slowly swallowed it. Temperature was subnormal; pulse and heart-beats were so weak and rapid that I could not count them. I again tried various styptics, but the result was as disappointing as before. I recalled that on several occasions of slight bleeding from small cuts, I used potassium permanganate with good results. I applied powdered potassium permanganate to the wound. The oozing immediately ceased and there was no recurrence of bleeding.

The action of the potassium permanganate in this case surprised me, and I mention it not with any enthusiastic conclusion, but merely that others may perhaps think of it in similar cases when the usual other agents fail to give good results. A deep cut on the forehead caused by a fall three months later healed without trouble.

321 East Tenth street.

UNUSUAL IDIOSYNCRASY TO ASPIRIN

G. BURTON GILBERT, M.D.
COLORADO SPRINGS, COLO.

The following case is reported because it seems unusual, and because of the violent reaction to an extremely small dose of aspirin. Judging from reports in the literature, poisoning from large doses of aspirin is relatively more frequent than that from small doses, which alone can show a distinct idiosyncrasy to the drug.

History.—On June 20, 1910, the patient, a woman aged 40, on complaining of slight frontal headache, was given, at 10 a. m., 5 grains of aspirin and $^{1}/_{60}$ grain strychnin sulphate, with instructions to take a similar amount of each at the end of one hour, if the headache persisted.

Symptoms of Poisoning.—Fifty minutes later I was called and found the patient very nervous, excited and frightened. She complained of feeling queer and dizzy. The headache was worse and pain in the inner corner of the right eye was intense. Both eyes were puffy and much swollen, especially under the lower lids. She complained of severe itching all over her head, which she scratched almost constantly. In about fifteen minutes the lips began to swell, reaching three times their normal thickness, and being tense and almost purple. This edematous condition also involved the upper portion of the throat. The voice became husky and breathing very difficult, the patient being unable to lie down. The finger-nails and ears were blue; the pulse was 110 and very irregular, while the temperature remained subnormal. The patient next complained of stiffness in the back of the neck and insisted that her throat was closing up. The itching extended over the ears and back, thence over the entire body, being accompanied by large blotches or wheals. Thus there was a generalized urticaria with a condition of the lips and throat resembling urticaria gigantea or angioneurotic edema.

Treatment and Result.—Cold compresses were applied to the lips, eyes and throat, and an ice bag was applied to the head. A hypodermic injection of $\frac{1}{4}$ grain of codein was followed in twenty minutes by another of 10 minims of epinephrin (adrenalin chlorid). Warm water containing a little salt was given until vomiting was induced at half past twelve. After this the patient felt somewhat better. She was given an injection of 1/60 grain of strychnin and a high enema. Within half an hour the swelling in lips, eyes and feet began to go down, the color improved and the breathing became easier. About 4 p. m., the patient fell asleep and slept for thirty minutes. By 6 p. m. the urticaria had disappeared except from the back of the neck and the only painful spot was in the right eye. On the following day the woman had entirely recovered except for considerable weakness and some aching in the back and legs.

The patient gave a history of having been poisoned on two other occasions; once from some spoiled sea food, when she was much sicker than anyone else in the party, and once from morphin which her physician had told her never to take again. She was also subject to chronic bronchial asthma. Therefore, the above may represent an asthmatic attack brought on, aggravated and complicated by an intense idiosyncrasy to aspirin.

817 North Cascade Avenue.

THE CAUSE OF THE IMMEDIATE PAIN AND ABSCESS FOLLOWING THE ADMINISTRATION OF SALVARSAN BY THE ALKALINE SOLUTION METHOD

B. C. CORBUS, M.D.
CHICAGO

The intravenous method of administering salvarsan will continue to hold its position as the most comfortable one for the patient, but whether or not it is as potent in the later stages of syphilis, time will have to tell. The trend seems to be toward some form of intramuscular injection.

As the alkaline solution method seems to be the most feasible and simplest in preparation and most far-reaching in its results in the later syphilids, it has been the aim of many observers to perfect it as far as possible. The two objections against this method have been the pain and lasting induration following the injection, the induration being followed at times by abscess formation. In all the reports published, such abscesses are sterile.

In my experience, covering 100 cases, I have found that the pain and induration are due to the sodium hydrate. The directions that accompany the tube of salvarsan advise that a 15 per cent. solution of sodium hydroxid be used in making the solution alkaline. One can readily see how easy it is to get an excess of sodium hydroxid; even one drop might cause an excess of alkalinity which would not only cause excess of pain, but in an ill-nourished individual might cause considerable necrosis. Following the Alt-Lesser technic, I used a 4 per cent. solution (normal sodium hydroxid) and my success was good in regard to pain and induration. Only twice have I observed an abscess. In one case, the patient was extremely debilitated, and in the other I had to deal with an excessively fat individual. In each of these cases, I believe the abscess was the result of the sodium hydroxid.

I now use a 2 per cent. solution of sodium hydrate. In this way any excess of alkalinity is more easily avoided, the initial pain is lessened, and I find that uniformly the coagulum formed in the muscles is absorbed, leaving the muscles in a soft, pliable condition ready for a second injection whenever necessary.

I first put the 0.6 gm. of salvarsan in a 25 c.c. graduated cylinder, and dissolve it in 8 or 10 c.c. of hot water. The sodium hydroxid is then added in small quantities until a clear solution is obtained, care being taken not to add any sodium hydrate in excess. Hot water is then added in sufficient quantity to bring the total solution up to 20 c.c.: 10 c.c. of this solution are injected deeply into the buttocks on either side. Great care should be used to keep the injected fluid out of the adipose tissue. The sodium hydrate solution should be sterilized before each injection. This is also true of all the glassware used.

32 North State Street.

Modern Conditions Require Evolution in Personal Hygiene.—Dr. Irving Fisher, president of the American Health League, in an article in the New York *Christian Advocate*, says that the health movement means a revolution in the habits of living now prevalent in this and most civilized countries. It seems a radical statement, yet no observer can fail to see that it is already in process of realization. The "outdoor life" undoubtedly has come to stay, including even the growing custom of sleeping out of doors. Likewise, largely under the influence of Mr. Fletcher, and with the approval and aid of scientific and medical authorities, says Fisher, the art of eating is changing rapidly. When hard foods, thorough mastication, and lessened consumption of protein have become universal, we may expect to see less of the dentist or the stomach specialist. The invention of cooking and preparing foods has been a much mitigated benefit. While it has widened the variety of man's diet, it has led to the decay of his teeth. Many of the other inventions of civilization have their unhygienic side. The invention of houses has enabled mankind to dwell in all parts of the world, but it is responsible for tuberculosis; especially after glass was devised, which, while letting in the light, keeps out the air. The invention of the alphabet and printing has made possible the accumulation of knowledge, but it has produced eye-strain with all its attendant evils. The invention of chairs has added to human convenience, but has led to spinal curvature and abdominal congestion. The device of a division of labor has added to wealth, but has destroyed the normal balance of mental and physical work, recreation and rest. Similar fault may be found with clothing, especially corsets, shoes and hats, and with numerous other contrivances. Yet it would be foolish, even if it were possible, to attempt to "return to nature" in the sense of abolishing civilization. We must not go backward, but forward. The cure for eye-strain is not in disregarding the invention of reading, but in introducing the invention of glasses. The cure of tuberculosis is not in the destruction of houses, but in devices for ventilation. It is a little knowledge that is dangerous. Civilization can, with fuller knowledge, bring its own cure, and make the "kingdom of man" far larger, even in respect to hygienic conditions, than "nature" people can even dream of. Unhygienic customs and fashions are exceedingly slow to yield, but they do yield in the end. It should be the part of intelligent men to lead in hygienic reform, not by intolerant and impatient abuse, but by the quiet force of example

Therapeutics

CONSIDERATIONS IN THE MANAGEMENT OF PULMONARY TUBERCULOSIS

The earlier treatment is commenced in pulmonary tuberculosis, the better for the patient, and the greater the chances of an ultimate cure. This axiom indicates the importance of an early diagnosis of the presence of the disease. One of the benefits which has resulted from the recent agitation in regard to tuberculosis is the more frequent recognition of the disease at its beginning. Before the present general interest in tuberculosis, it was not uncommon for patients to go untreated until they had reached an advanced stage of the disease. Less often, but altogether too frequently, patients were under the care of a physician for months before the real nature of the trouble was recognized. So much has been said and written on this subject within the last fifteen or twenty years, that no physician is excusable for neglecting to recognize the nature of the disease as soon as he undertakes the treatment of the patient.

At this day, it is hardly necessary to enumerate the symptoms which would lead one to suspect the presence of the disease and to act on his suspicion by making a thorough investigation of the case, including a careful physical examination. Among these symptoms may be mentioned loss of strength, loss of appetite, loss of weight, loss of physical and mental energy, increased body temperature, increased rapidity of the heart, increased rapidity of the respiration, cough, especially when accompanied by vomiting, and hemoptysis. When any of these are present, if some other cause cannot be found, the presence of tuberculosis should be suspected, and the possibility of its existence should not be given up while the symptom exists, or until some other cause for it has been found.

As soon as it is definitely determined that the patient is suffering from pulmonary tuberculosis, several important questions arise and demand an early solution. In the first place, it must be determined whether the patient shall be treated at home, or shall be sent to a sanatorium in the neighborhood of his home, or shall be ordered a complete change of climate. Certain conditions may determine that the treatment shall be conducted for a time at least, in his own home. When the patient is found to be in an advanced stage of the disease, with a high temperature, rapid pulse, poor appetite, frequent cough, and copious expectoration, it is, in most cases, poor judgment, and cruel, to advise such a person to leave home and friends in order to have the very slight advantage which change of climate will afford him. On the other hand, it may happen, in rare instances, that even patients in the very worst condition improve, contrary to our expectations, hence if the patient manifests considerable powers of natural endurance, and is not likely to be unfavorably influenced by separation from his friends, he may be allowed, even if the symptoms are serious, to try a change of climate. But such cases are certainly rare. Many patients must be treated in their own homes because they cannot afford to leave their homes and be at the expense of traveling and paying board in a sanatorium or health resort.

If the patient while showing sufficient symptoms to enable the physician to make a positive diagnosis is at the same time not very weak, not suffering from much fever, and not coughing very much, it may be wise for the physician to suggest a very radical move. Unquestionably, in some instances, it is the duty of the physician to advise the family, for the sake of the stricken member, to sever all relations with the community in which the disease has arisen, to sell their home if necessary, to dispose of their business if they have one, and to remove as a whole to a climate where the patient may recover from his disease, and to remain there permanently. This advice may be based on the now generally recognized fact that, if a person suffering from incipient tuberculosis goes to a climate where he recovers from the disease, he should continue to reside there, probably for the remainder of his life, certainly for many years. The converse of this is often true, viz., that patients who have recovered from tuberculosis in any particular climate, when they leave this climate and return to their former residence, often have a recurrence of the disease and go from bad to worse, or frequently develop pneumonia and die of that disease.

When a change of climate has been determined on, there is a wide range for choice in the selection of the particular climate, and it cannot always be determined in advance what climate will be best for the individual patient. Sometimes the patient's own experience of feeling better in summer or in winter will determine the selection for him of a mild or a cold climate. Often it will be found that patients who were born and have passed the early years of their life in a northern climate will do better, when making a change of climate, to select a cold climate. On the other hand, people who were born and raised in a warm climate, and who habitually feel better in summer, will usually do better in a warm climate, such as that of Florida or California.

Those who have a great tendency to have new foci in lung tissue break down, and those who have profuse bronchial discharge, and those who have fibroid phthisis, will generally do well in Arizona and New Mexico.

Some patients with pulmonary tuberculosis do well at the seashore, as has been observed to be the case with children suffering from bone and joint tuberculosis.

On the other hand, many do well in a mild climate, such as in the hills of the Carolinas.

Those who seem likely to do well in a cold climate, may be recommended to go to the Adirondacks or to Colorado.

Altitude is a thing that must be considered in selecting a climate for the tuberculous patient, and it will be found that those of nervous temperaments, with weak, rapidly acting hearts, those with high fever, and those with a tendency to hemoptysis, usually do not do well at a high altitude. On the other hand, those who are depressed by the heat of summer, but who are stimulated and feel stronger in winter, frequently do not do well in a low altitude like that of southern California or Florida. Whatever opinion may have been formed by the physician in advance, if his opinion is not confirmed by the experience of the patient, a change should be made to a climate of a different character.

It should never be forgotten that very sick patients do not stand travel and separation from their friends well, and that patients who find a climate in which they can live comfortably are foolish to leave it.

If the family of a patient is in moderate circumstances, and the patient is in an early stage of the disease, removal to a sanatorium in the neighborhood is frequently advisable. In the first place, this removes a focus of infection from the family and friends of the invalid. It also places him in a position of being instructed as to the proper care of himself. These are very important considerations. Further, his symptoms are daily, perhaps hourly, observed; he is required to do what is best for himself, and he is furnished with abundant and nutritious food. These are of great importance, and most patients at the beginning of the disease are benefited by them, even in the absence of any very marked change in climate. Much may be accomplished by treatment in such an institution as has been lately demonstrated, but it is perhaps too much to claim that such treatment is just as good as treatment in a more distinctly advantageous climate. Unquestionably certain climates are far better for certain tuberculous patients than others; and, unquestionably, for many, a considerable altitude is better.

Wherever the patient is treated, the matter of air is of first importance, as it is also in the preventive treatment of the disease. The patient should remain out-of-doors, if possible, during the whole twenty-four hours. Space forbids here a discussion of the various methods which may be adopted in order to secure this. Shacks, porches, balconies, and window tents may be utilized in appropriate cases. If it is entirely impracticable for the patient to sleep out-of-doors, or while suitable provisions are being made for this, he should at least sleep in a room with the windows open, and in a room to which sunshine has access during the day. At the same time that he is enjoying the benefit of this fresh air, often cold air, he must be adequately protected so that he will not suffer from the cold. He should wear woolen clothing, and be covered with light woolen blankets supplemented by adequate bed quilts and puffs. In cold weather, the head and ears must be protected from chilling, and also the patient must be kept comfortable; *he should be protected from draughts.*

In the advanced stages it is not wise to insist on absolute out-of-door treatment in the coldest weather, and often not even in milder weather. If the patient is weak, he may be treated with benefit within his usual sleeping room, if the windows are allowed to remain open, and the cold air warmed, but the room not allowed to become over-heated.

The question of rest is pre-eminent, and the importance of rest has been increasingly recognized by the medical profession during the last twenty-five years. If the patient has fever even of moderate degree, it will do him very little good in any case, and in most cases will do him positive injury to exercise or even to sit up out of bed. Exercise, even walking or sitting up, is now generally recognized as being almost as detrimental to the patient with tuberculosis as to a patient with typhoid fever. It is necessary to diminish oxidation and to conserve strength as much as possible, and this can only be satisfactorily accomplished by keeping the patient in bed, this to be continued as long, at least, as the temperature rises to 100 F. at any hour of the day, and probably as long as it rises above 99 F. While this is the rule, it is possible that in exceptional cases in which the temperature rises to 100, but not above, the patient may be benefited by brief exercise each day, but these instances are exceedingly rare, and this privilege should be granted only in chronic cases with low fever and not very rapid pulse. A weak and rapid pulse is also a strong indication for rest in bed.

Next in importance to rest and fresh air comes the question of diet. Many patients have been tormented and abused by overfeeding, which has been a fad at many tuberculosis sanatoria. It is now generally recognized by the best authorities on the treatment of pulmonary tuberculosis that overfeeding beyond the provision of an adequate physiologic supply of food is not wise. The character of the food administered should depend somewhat on the digestive power of the patient. If there is much fever and the digestion is weak, a strictly milk diet may be employed for a limited time. This may be supplemented, as the fever diminishes, and the digestive power increases, by broths and gruels. As improvement continues, eggs may be added. For a convalescent patient and the patient who has not much fever and a good digestion, an ordinary mixed diet (excluding indigestible and innutritious foods) including all easily digestible and nutritious foods, such as milk, eggs, fresh meats, stale bread, boiled rice, baked potatoes, fresh vegetables and fruit in season, will be found useful.

If the patient is very ill and has much fever, the rest in bed implies refraining from doing any business, from corresponding, from reading, or from seeing much company.

The fresh air, the rest, and the diet are the sheet anchors of treatment. Medicines are entirely subordinate to these hygienic measures, and yet, in many cases they are of great value.

Barrels of cod-liver oil have been consumed by patients, and not infrequently with considerable benefit, improving the nutrition and lessening the cough and expectoration. It should, perhaps, be regarded as a food rather than as a medicine, and as a food, unquestionably it will prove of value in many cases.

For many years, the hypophosphites, and especially the hypophosphite of calcium, and in some cases the hypophosphite of sodium, have been used with apparent benefit. Recent studies of the physiologic action of calcium on cell growth and nutrition may lead to a renewal of interest in the hypophosphite of calcium. The use of a combination of half a dozen different hypophosphites need only be mentioned to be condemned. There is no reason for the use of such a combination except the desire of a physician to order some one of the many proprietary hypophosphite combinations on the market.

So many unkind things have been said by such distinguished authorities about creosote, that one hesitates to mention it in connection with this subject, but if one feels impelled to administer an antiseptic drug in the treatment of this disease in which an efficient antiseptic would be so highly esteemed, he cannot do better than administer the carbonate of creosote. It will rarely injure the stomach, and it may promote digestion and nutrition by preventing gastric and intestinal fermentation, and may possibly, and many men believe that it does actually, have a favorable effect on the pulmonary pathologic process.

For the fever it is usually not necessary to give any drug, the light diet and the rest in bed in cool fresh air usually accomplishing the desired result.

If there is much cough, some simple codein expectorant mixture may be given. Such a mixture must not be sweet. The following are suggestions for treatment of the cough:

R.	gm. or c.c.		
Codeinæ sulphatis	20		gr.iv
Ammonii chloridi	5		ʒiss
Syrupi ipecacuanhæ	5	or	fl.ʒiss
Syrupi acidi citrici	25		fl.℥i
Aquæ	ad 100		ad fl.℥iv

M. et Sig.: A teaspoonful, in water, every two or three hours. Shake.

Or,

R.	gm. or c.c.		
Codeinæ sulphatis	20		gr.iv
Ammonii chloridi	5		ʒiss
Syrupi acidi citrici	25	or	fl.℥i
Aquæ	ad 100		ad fl.℥iv

M. et Sig.: A teaspoonful, in water, every two or three hours. Shake.

Or, if the cough is just a throat tickling, without much expectoration, the following is often efficient:

R.	gm. or c.c.		
Codeinæ sulphatis	20		gr.iv
Alcoholis	10		fl.ʒiii
Spiritus chloroformi	5	or	fl.ʒiss
Syrupi tolutani	50		fl.℥ii
Aquæ	ad 100		fl.℥iv

M. et Sig.: A teaspoonful, in water, every three hours. Shake.

If there is profuse expectoration, a 5-grain tablet of terpin hydrate crushed by the teeth and taken with water four or five times in twenty-four hours is efficient in diminishing the amount of bronchial secretion.

Coughing that results in vomiting, or at least in retching is very likely to be due to either pharyngeal or lingual tonsil irritation and not to any trouble in the stomach. Gargling with some warm alkaline solution, as the *liquor antisepticus alkalinus*, diluted with equal part of warm water, or a Seiler's tablet solution, or gargling with one-fourth of a teaspoonful of salt and one-fourth of a teaspoonful of bicarbonate of soda to one-half a glass of warm water, will relieve and soothe the throat and stop this kind of irritation. Slippery elm and flaxseed tea are also valuable aids in stopping this lingual tonsil cough.

Codein is the best opium sedative to use. It does not dry up the secretions as does morphin, or interfere with digestion as does morphin, and is not as depressant as heroin.

The question of stimulants is one which often arises, and concerning which there is much discussion. In the advanced stages of the disease, where there is great prostration and no hope of recovery, alcoholic stimulants may be allowed on the ground that they increase the comfort of the patient and make him more reconciled to the wretchedness of his condition; otherwise, they should not be advised for habitual use. The various extracts of malt which contain a small percentage of alcohol are not to be included in this condemnation, and may often be administered with considerable benefit.

As has been urged before in these columns, unless a patient has become cured in a new climate and intends to remain there with new possibilities of occupation, he should, after recovery, return to the occupation to which he is accustomed, or to that which he left when he became ill, unless it is a peculiarly dangerous one for this disease.

Histologic Changes in Hodgkin's Disease.—F. Eve, in the *Practitioner*, states that the histologic changes in Hodgkin's disease are in the connective tissue framework and in the endothelial elements of the gland; and the diagnostic features are thickening of the stroma, with the presence of large multinucleated cells, and of cells rich in eosinophil granules; whereas in primary malignant disease a small round or lymphosarcoma is found, originating from the adenoid tissue, or a round or spindle-celled sarcoma arising from the stroma. Occasionally tuberculous glands present after removal the same pink homogeneous section as lymphadenomatous glands, and show no macroscopic evidence of caseation. Their nature can only be determined with the microscope.

THE LOST ARTS

We are sometimes made to feel humble in the midst of our triumphal march of progress, by being told that in the ancient civilizations men did many things better than we do them now, and that at the best we ought to recognize that what we consider discoveries are mostly but rediscoveries. Probably we need this sort of corrective to self-satisfaction; nevertheless, it seems likely that modern iconoclasts will destroy its efficiency. "The lost arts" is a catch-word by which we set great store, and according to Dr. W. D. Richardson[1] its popularity in this country rests largely on the prominence given it by Wendell Phillips in his lecture on this topic, which he repeated two thousand times, more or less, in lyceum courses all over the country. Dr. Richardson examines the evidence on which rest the claims of unusual chemical achievements by the ancients, and finds it worthless.

The ceramic arts, it is true, did yield products at certain times which were not duplicated later, but it was not the art but the materials which were lost, for the results obtained by the potter depend in large measure on the particular clays he has to work with, and when a certain supply of clay gave out, a particular form of pottery might be discontinued. Fabulous tales of glass, with unequaled beauty and unbelievable ductility and malleability, are of wide popularity. To be sure, the ancients did make a sort of glass, opaque or translucent, often possessed of great beauty from the standpoint of the fine arts; but when it became possible to make a good transparent product the imperfect if more beautiful form lost its market and ceased to be made. Recently the interest in objects of art made of opaque and translucent glass has revived, and this glass is again being manufactured, but the art of making it was never entirely lost. So, too, the stories of marvelous cements, plasters, dyes and pigments, vastly superior to anything now available, are found on examination to possess no truth.

We must always remember that only the best examples of the materials used by the ancients can now exist; it is not at all fair to judge their entire work by these exceptional specimens. As we have pointed out in these columns before,[2] the reputed lost art of embalming, as performed by the ancient Egyptians, was nothing more marvelous than simple pickling in a brine of common salt; its wonderful efficiency was contributed by the dry climate in which the bodies were left. The oft-repeated statement that the same people filled carious teeth with gold according to the most modern practice, is also a myth. The building of the pyramids involved no preternatural knowledge of mechanics, but simply the inhuman use of myriads of slaves. Some arts, of course, depend on dexterity and manual skill, best transmitted by the personal training imparted by one artisan to another, rather than on scientific principles. If, therefore, the demand for the objects so produced becomes lessened, as by war, social disturbances, or change of customs, the arts may be forgotten. Real science, however, does not go backward, and to such extent as arts depend on science rather than on exceptional personalities, or on the continued maintenance of a high level of dexterity and skill, they cannot well be lost.

ANTIPLAGUE MEASURES

We have referred previously[1] to the outbreak of plague in Manchuria, which promised to be unusually severe and extended, and the death-rate of which was extremely high. On account of the appalling nature of the outbreak, the Chinese government was led to call for international assistance with a view to gaining control over the disease. Scientific studies of plague in a latitude so far north and under the conditions of life to be found there should be productive, and there should be elicited new facts regarding the epidemiology, especially of the pneumonic form of the disease.

Recent official reports and press dispatches indicate the marked diminution in the severity of the outbreak in North China, especially in those centers in which it first appeared. On account of the extension from those centers, however, new foci have been established, and it is safe to say that a wide territory is now affected, thus rendering more difficult the precautionary measures as to sanitation that have been inaugurated.

Notwithstanding the limited trade relations with ports in Manchuria and North China, some apprehension arose as to the possible dangers to our ports from such a severe epidemic, but the precautions taken in Manchuria itself by the Chinese government and other governmental agencies, and by railway officials and others interested, were undoubtedly a great protection to international shipping and particularly because the disease was of the pneumonic type. Besides, there is reliable authority for the belief that there was no infection of the rat population, which, when infected, constitutes the greatest danger to international commerce.

[1] Feb. 11, 1911, p. 45.

Additional precautions were also afforded through sanitary supervision of passenger and freight traffic by medical officers of the Public Health and Marine-Hospital Service stationed at the principal ports of China and Japan. The quarantine system of the Japanese government, on account of the location of that country in the line of transpacific ships from China to the United States, also serves as a barrier to the extension of epidemic diseases. With these precautions abroad, and the careful supervision maintained over arriving ships, their passengers and cargoes, as well as a campaign for the extermination of rats on all vessels at home ports, required under the national quarantine regulations, there appears to be no likelihood of the introduction of the infection of plague as a result of the recent outbreak referred to.

The question arises as to the measures taken to prevent the spread of the infection that has been shown to exist on the Pacific coast. The last outbreak in California began Aug. 12, 1907, from which date to Jan. 30, 1908, there occurred in San Francisco 159 cases with seventy-seven deaths.

Were it not for the fact that the infection had secured a hold among ground-squirrels, all probability of further cases would have ceased, since the disease was eradicated from San Francisco and other bay cities. Those cities are now protected, however, by a squirrel-free zone established and maintained by the sanitary authorities interested.

The first infection among squirrels was found in August, 1908, which indicated that these rodents might serve as a potential agency in fostering the infection, and emphasized the necessity of a systematic and vigorous campaign for their extermination. According to the weekly Public Health Reports, this work has been carried on with the view to the destruction of known foci of infection, determination of the extent of the area of infection and general squirrel extermination.[2]

That the plague-suppression measures have been extensive is shown by the fact that since July 1, 1908, they have cost the federal government approximately $800,000, and the State of California not less than $500,000. Until March 4, 1911, there had been collected 992,247 rodents, 937 of which were found to be infected. Squirrels have been collected over a considerable area of the State of California, and the area of infection appears to be definitely determined. In addition to the maintenance of the squirrel-free zone mentioned, the work carried on includes the destruction of known foci of infection, and the work of squirrel extermination is becoming general, being actively carried on in ten counties.

While the work is being conducted by an officer of the Public Health and Marine-Hospital Service in cooperation with state and local health authorities, much is being done by ranch-owners and farmers, and county authorities are aiding extensively by the appropriation of money and the employment of inspectors.

From the character and extent of the work done and the plans for its continuance, the plague situation on the Pacific coast should cease to be a menace; but the problem of squirrel extermination is a large one, and there is necessity of a clear understanding on the part of the public, not only of the difficulties involved, but of the strenuous measures that have been taken. Those having charge of this work not only should be provided with ample funds, but should also be supported by an enlightened public opinion.

EXPERIMENTAL TUBERCULOUS REINFECTION AND ITS BEARING ON HUMAN TUBERCULOSIS

In a series of experiments, Römer and Joseph[1] show that in guinea-pigs and sheep a preexisting tuberculosis protects wholly or in part against a later experimental infection. The procedure in general is briefly as follows: An emulsion of tubercle bacilli in physiologic salt solution is penciled over a short incision in the skin of guinea-pigs which some time previously have been infected with tubercle bacilli subcutaneously. Guinea-pigs which were healthy, except so far as the incision and its treatment were concerned, served as controls. Various experiments like this modified in different ways gave the same results. The previously tuberculous pigs were completely immune to cutaneous reinfection, and the wounds made in the skin for the purpose of reinfection healed promptly, whereas the control animals died from disseminated tuberculosis. Guinea-pigs were also immune to reinfection when the bacilli used in the experiments were obtained directly from the organs of tuberculous animals. Experiments on sheep gave the same results as those on guinea-pigs, the reinfected sheep being wholly immune to quantities of bacilli which in control animals caused death from wide-spread pulmonary tuberculosis in the course of eight weeks.

Now it is generally assumed and believed that in man the resistance to tuberculosis increases with age. The young are especially prone to tuberculous infection, only too often of a progressive type running a rapid course. It is usually said that in the very young there exists a physiologic state or "disposition" which renders them more susceptible to infection and less resistant than adults. This predisposition is regarded as specially marked in the children of tuberculous parents. Such children are exposed very freely to infection because of the close contact in which they are placed with those about them and this may explain in part at any rate the apparent increased susceptibility. It may be noted that experiments with the young of tuberculous animals do not appear to indicate that there is any special susceptibility to tuberculosis in them. The large percentage of positive tuberculin reactions in children points unmistakably in the direction indicated, namely, the ease with which infection occurs early in life. Indeed, it seems not improbable that, at least in the large cities, almost every person is infected with tuberculosis by the time he reaches puberty. Hence it lies near at hand to conclude that the increasing resistance to tuberculosis as age advances may be largely the result of infection with tubercle bacilli early in life.

---

[1] Römer and Joseph: Beitr. z. Klin. d. Tuberk., 1910, xviii, 281.

In the struggle now waged everywhere against tuberculosis the efforts are not always directed toward the point where most effective progress might be achieved. Thus, it should always be borne in mind that in the adult the susceptibility is relatively less than in the young. It is the child that we should aim to protect by all means and especially against the most dangerous sources of infection, namely, the constant association with the tuberculous.

Current Comment

PUBLIC HEALTH PERSONNEL BILLS

Two bills,[1] S. 1182 and H. R. 5599, which deserve the cordial support of those interested in increasing the efficiency of the federal health agencies, have been recently introduced into Congress, one by Senator Owen and one by Representative Charles G. Edwards. These measures relate entirely to the personnel of the Public Health and Marine-Hospital Service and are designed to make that service more attractive to young medical men. While varying in phraseology, the bills have in view the same object—increase in pay. For over a century there have been three national medical services—the Army, the Navy and the Public Health and Marine-Hospital Service—and the requirements for admission to all have been equally exacting. In 1871, the Marine-Hospital Service was organized on its present basis and the appointments and promotions therein were placed on the merit system. In 1889, the pay of its officers was placed on a parity with that of the other medical corps, but in 1908, when the pay of the Army and the Navy medical corps was materially increased, that of the Public Health and Marine-Hospital Service was not similarly raised. The annual salary of a physician entering the Navy at the present, for example, is within $45 of that of one who has been in the Public Health and Marine-Hospital Service for fourteen years. As a result, it is difficult to retain the best men in the service and almost impossible to recruit its ranks with men of proper qualifications. The present bills are designed to overcome these difficulties by more nearly equalizing the pay of the three services. The officers of the Army and Navy receive certain allowances and perquisites which are not contemplated for those of the public health service, so that on the whole the pay of the former would continue somewhat higher. The proposed increased pay in the public health service, however, would doubtless attract a class of young physicians who prefer a civilian to a military career. Within the last few years Congress has repeatedly recognized the justice and necessity of such legislation as is now proposed; in fact every provision of the Edwards bill has at one time or another passed either the Senate or the House of Representatives; but the question of pay, unfortunately, has become so involved in questions of function that bills passing one house have not been acceptable to the other. Thus some members of Congress have opposed all bills for increased pay which did not impose additional duties, while others have not favored bills providing for increased function on the ground that their passage would imperil the chances for a federal department of health. It is to be hoped that this question will be considered solely on its merits, as all interested in public health work, in or out of Congress, agree as to the need and justice of increasing the pay of the officers of the public health service.

OPIUM-CONTAINING PROPRIETARIES

In the "Propaganda for Reform" department of this issue, appears a report of the Council on Pharmacy and Chemistry on a proprietary product called Pantopon and a contribution from the chemical laboratory on another proprietary—Papine. While both are opium preparations—that is, owe their chief or entire activity to morphin—there the resemblance ceases. Papine, according to our chemists, is merely a solution of morphin. The manufacturer, a typical St. Louis proprietary firm, claims for this preparation the impossible, namely, that it contains morphin minus morphin's harmful properties; and the unthinking physician is thus led to prescribe morphin recklessly and without due consideration of its dangers. Pantopon, on the other hand, is made by a firm whose products, in a number of cases, have been accepted by the Council for inclusion with New and Nonofficial Remedies. The composition of Pantopon is not secret, for it is definitely stated that it consists of the alkaloids which naturally occur in opium, freed from the other constituents of opium—extractive matter, etc.—in the form of hydrochlorids. Papine and Pantopon, however, resemble each other in that they have names which do not sufficiently indicate to the physician their chief constituent, morphin, and they are, therefore, a menace to the public. In spite of the testimonials for both these products, we believe that physicians would not be far amiss if they would continue to use the drugs, morphin and opium, whose value—and dangers—they know.

SELF-SUPPORTING CRIPPLES

The compensation of workmen in factories and other industries for injuries sustained in the line of their work is a live question at the present time. Many European countries for years have had laws concerning employers' liability and workmen's compensation. A step further in this humanitarian line is the education of persons prevented from following their former occupation or trade by reason of injury. This is accomplished by the establishment of schools wherein such persons are taught various trades by which they may earn a livelihood, even in their crippled condition. At Charleroi, France, at the instigation of Pastur and Caty,[1] a school has been established for this purpose. Among the trades taught to people injured in the industrial establishments of this manufacturing city are brush-making, the making of paper boxes, turning, binding, stenography and typewriting, drawing and other forms of manual training. The trade which the crippled individual must take up is, of course, governed in a measure by the nature of the injury; for instance, individuals crippled in the legs would follow occupations allowing them to sit at their work. In one case described in the article referred to, a man with both arms amputated near the shoulder, by means of a mechanical appliance about his neck, follows the trade of a wood-turner. In another instance, an individual with both hands gone was enabled to make brushes. The many occupations which may be followed by the blind are more or less familiar. Similar schools are conducted in other places, at present mostly through private philanthropy. There is no reason why such schools should not be supported by the state: this undoubtedly will be a development of the future, following the securing of efficient employers' liability and workmen's compensation acts.

UNIVERSITIES AS OBJECT-LESSONS IN HYGIENE

"Preventive medicine is the cheapest life-insurance which can be taken out." With this sentence Ravenel and Frost of the hygienic committee of the University of Wisconsin conclude an admirable paper in this issue on "The Formation and Functions of Hygienic Committees for Universities," which gives a history of the formation of the committee on hygiene of the university and its achievements. The need for such a committee in this instance is abundantly shown. Conditions in the University of Wisconsin are probably representative of conditions to be found in many other universities and in smaller schools as well. The worth of the paper lies not so much in the statement of the good accomplished in this one school, as in the admirable scheme of investigation employed and the measures adopted for bettering the hygienic conditions of the buildings and health of the students, which may serve as a model. Their studies have brought them to the following conclusion: "Schools, colleges and universities ought to lead in sanitary construction, sanitary equipment and sanitary care. Class-rooms and laboratories ought to be models of sanitary excellence as well as of convenience and attractiveness. The educational value of such buildings far outweighs any additional expense involved." It might be added that the lessons of this paper would apply with still greater force to industrial establishments employing large numbers of men and women, with longer hours and more exacting conditions than in the schools; and the sentence first quoted might be changed to read, "Preventive medicine is the cheapest industrial insurance which can be taken out."

THE SCOPE OF THE NEXT PHARMACOPEIA

Although the Committee on Revision of the United States Pharmacopeia was appointed nearly a year ago, it has issued no report to show what progress is being made. While there are doubtless good reasons why no such report has been published, the committee should realize that the medical profession is interested as never before in the question of what should be added to, or deleted from, the next edition of the Pharmacopeia. It may not be amiss to point out that physicians frequently accept at their face value claims made by interested persons regarding the therapeutic action of certain drugs. This applies to both proprietary and non-proprietary articles. There is a tendency on the part of certain doctors to prescribe such drugs, even after they have been shown to be worthless, especially if the preparations have been admitted to the official standards and consequently included in text-books. An example of the official recognition — not pharmacopeial — of a valueless preparation is that mixture of pepsin and pancreatin known as Elixir Digestivum Compositum, N.F. A formula for this preparation was put in the National Formulary because of the very extensive use of a nostrum widely exploited with most extravagant and untruthful claims. This nostrum has been and is widely used, not because it is of any therapeutic value, but simply and solely because it has been extensively and extravagantly advertised. It is well known that liquid preparations of pepsin and pancreatin are therapeutic absurdities and chemical impossibilities. So, while a drug may be widely used, it does not necessarily follow that it is of any value whatever. Many text-books contain recommendations for the use of drugs simply because some other text-book recommended them, not because they are of any value. It is to be hoped that those who select the articles to be included in the next Pharmacopeia will have some other basis for inclusion than the mere fact that they are being used. If the Pharmacopeia is to be a scientific treatise on drugs, and is to enlist and keep the respect of the medical profession, the adoption of some other standard becomes inevitable.

Medical News

ALABAMA

Tag Day in Montgomery.—The Young Ladies' Auxiliary of the Montgomery Antituberculosis League will hold a Tag Day, April 29, the proceeds to be devoted to the purchase of a site for a day camp for tuberculous patients.

Antituberculosis Society Election.—At the annual meeting of Jefferson County Antituberculosis Association, held in Birmingham, April 16, Dr. Benjamin L. Wyman was elected first vice-president, and Drs. Cabot Lull and Cunningham Wilson were elected directors. By the efforts of the association, a tuberculosis camp has been established on Red Mountain. The most recent addition to the camp is a dining room pavilion just completed which will accommodate seventy-five patients.

Personal.—Dr. James T. Fowler, Dothan, has succeeded Dr. Edgar R. Burns, Sheffield, as medical member of the State Convict Board.——Dr. George I. DeWald, state bacteriologist, has resigned and will resume practice at his home in Philadelphia.——Dr. Jackson T. Brown, Riverside, has been appointed road commissioner of St. Clair County.——The residence of Dr. James T. Searcy on the State Hospital grounds, Tuscaloosa, was destroyed by fire, March 5.

ARKANSAS

State Society Meeting.—The annual meeting of the Arkansas Medical Society will be held in Fort Smith, May 9-12, under the auspices of the Sebastian County Medical Society.

Sanitarium Established.—A number of physicians of Missouri and Kansas have united in the organization of a sanitarium company at Sulphur Springs. The building is a five-story, stone structure containing 100 rooms with modern equipment; is situated in a well kept park of 40 acres, which contains also an 8-acre lake and five mineral springs. Dr. J. Morse Griffin is president of the company, and Dr. Edward R. Tenney, medical superintendent.

Needs of the Sanatorium.—After meeting with the board of trustees of the State Tuberculosis Sanatorium, the joint committee of the legislature has decided to ask for an appropriation of $25,000 for construction work, and of $60,000 for maintenance of the institution for two years. The sanatorium at present accommodates seventy patients, but with the infirmary and additional quarters proposed, the capacity will be increased to 100. The cost of maintenance is estimated at $600 per annum per patient.——A bill has passed the senate appropriating $85,000 for a state tuberculosis sanatorium and the bill is at present pending in the house with fair prospects of passage.

CALIFORNIA

Personal.—Dr. Addison Morgan, San Diego, has been appointed autopsy physician to the coroner of San Diego County. ——Dr. Annette Buckel, Piedmont, was the guest of honor at a banquet of the Professional Women's League, Oakland, March 21.

State Society Meeting.—At the annual meeting of the Medical Society of the State of California, held in Santa Barbara, April 18 and 19, Del Monte was chosen as place of meeting in 1912. The following officers were elected: Dr. Thomas W. Huntington, San Francisco, president; Drs. Charles S. Stoddard, Santa Barbara, and John R. Walker, Fresno, vice-presidents; and Dr. Philip Mills Jones, San Francisco, secretary-treasurer (reelected).

COLORADO

Ball for Nurses.—The first annual ball of the Denver Visiting Nurses' Association was given April 18, and netted for the association about $1,000.

Hospitals in State.—The last report of the State Board of Charities and Corrections states that there are eighty-two hospitals in Colorado, of which twenty-two are private or semi-private institutions for the care of tuberculous patients.

Personal.—Dr. Mary E. Phelps, Canon City, has returned after a year abroad.——Dr. William C. Mitchell, Denver, has gone to Europe.——Dr. Richard S. Grant, Colorado Springs, was painfully injured in a runaway accident, April 4.—— Dr. Peter H. Heller, Pueblo, who has been ill in St. Mary's Hospital, has recovered and resumed work

Dispensary Will Build.—The Free Medical Dispensary, established six months ago under the direction of the North Denver Italian Mission, has been so successful that plans are now being made for the erection of a building to cost $20,000. About $7,000 of this amount has already been subscribed. The dispensary has treated so far more than 400 cases a month.

Consumptive Relief Society.—The Jewish Consumptive Relief Society, Edgewater, celebrated its seventh annual meeting, April 16, and laid the cornerstone of the second New York Ladies' Auxiliary Pavilion and the cornerstone of the Beth Jacob Synagogue, the gift of I. Solomon, Denver, in memory of his son. During the last year the society has spent $65,000 and now has a balance of $10,000 in the treasury.

DELAWARE

Wilmington Appoints Vaccine Physicians.—The city council has reelected the following vaccine physicians: Drs. John McGrath, Harry G. Buckmaster, Wilbur E. Postles and Harvey B. Patton.

Quarantined Immigrants Revolt.—About 200 immigrants, detained fourteen days in quarantine in Lewes because of an outbreak of small-pox on the steamship *Verona*, became vexed at the non-arrival of the steamship *Taormina*, which was expected to arrive April 14 and take them to Philadelphia, overpowered the few guards and marched to the Lewes railway station. They were refused tickets and were driven back to quarantine by armed guards, assisted by sailors from the United States Revenue Cutter *Onondaga*.

GEORGIA

Personal.—Drs. Josephus J. P. Bowdoin, Adairsville; Fred V. Turk, Stilesboro, and George Will Battle, Cassville, have been appointed members of the board of health of Bartow County. ——Dr. Philip H. Camas has been appointed medical inspector of the high school of Baxley.

Health Boards Organize.—The Association of State, County and Municipal Health Boards was organized at Rome, April 18, at a meeting of the Georgia Medical Association and the State Board of Health. Dr. James C. Bloomfield, Athens, was elected president; Dr. Olin H. Weaver, Macon, vice-president, and A. V. Wood, Brunswick, secretary.

State Society Meeting.—The Medical Association of Georgia held its annual meeting at Rome, April 19-21, under the presidency of Dr. Edward C. Davis, Atlanta. Augusta was selected as the next place of meeting, and the following officers were elected: president, Dr. William L. Fitts, Carrollton; vice-presidents, Drs. Robert M. Harbin, Rome, and T. E. Bradley, Cordele; secretary-treasurer, Dr. William C. Lyle, Augusta; delegate to the American Medical Association, Dr. William Doughty, Augusta, and alternate, Dr. Edgar G. Ballenger, Atlanta.

ILLINOIS

Asks New Hospital.—Several practitioners of Aurora have started a petition to Bishop Muldoon requesting that the Sisters of Mercy be allowed to erect a hospital on the west side, as the hospitals in Aurora and St. Charles are already overcrowded.

County Society Room Planned.—At a recent meeting of the Montgomery County Medical Society, it was proposed to have a room built on the east side of the Litchfield Hospital 20 by 26 feet to be used as a meeting place and clinic room for the society. The cost of the proposed addition is $2,000.

State Society Meeting.—The Illinois State Medical Society will hold its annual convention in Aurora, May 16-18. Dr. Herman A. Brennecke, chairman of the committee on accommodations, appreciates that accommodations at the hotels will be inadequate and is making early arrangements for accommodations in private houses. Those desiring accommodation should communicate with Dr. Brennecke.

Personal.—Dr. and Mrs. William H. Kauff, Princeton, have returned after a winter spent in Florida and the east.——Dr. William L. Gray has been elected president of the board of education of Champaign.——The office of Dr. James E. D. Silcox, Rio, was destroyed by fire, April 9, with a loss of $2,000, partially covered by insurance.——Dr. Edwin L. Winslow, Danville, has been reelected physician of Vermilion County.

Society Meetings.—At the meeting of Greene County Medical Society, held in Kane, March 10, resolutions were adopted respectfully requesting the legislature and governor to adopt such laws as will give to the state only high class medical schools, and also asking the legislature and governor to establish and maintain one educational standard and one medical examination, except in therapeutics, for all who are licensed to treat human disease, and endorsing the work done, and the standard of medical education adopted by the Council on Medical Education of the American Medical Association. Dr. Henry A. Chapin, White Hall, was elected delegate, and Dr. Henry W. Chapman, White Hall, alternate delegate to the state medical society.——At the annual meeting of the McLean County Medical Society, held in Bloomington, April 6, the following officers were elected: president, Dr. Robert A. Noble. Bloomington; vice-president, Dr. Ferd. C. McCormick, Normal; secretary-treasurer, Dr. Thomas D. Cantrell, Bloomington; censors, Drs. Edward L. Brown, John W. Dobson and Ralph D. Fox, all of Bloomington; delegate to the state society, Dr. Edwin P. Sloan, and alternate, Dr. Ernest B. Mammen, both of Bloomington.——At the annual meeting of Waukegan Physicians' Club, April 4, Dr. Fremont C. Knight was reelected president; Dr. William C. Bouton, vice-president, and Dr. Charles E. Daniels, secretary-treasurer.

Chicago

Bequest for Hospital.—The county judge at Kenosha has admitted to probate the will of the late Caroline Durkee, which devises the entire estate to St. Luke's Hospital, Chicago, and Racine College, Racine, Wis.

Personal.—Major Daniel W. Rogers, M. C., Ill., N. G., chief sanitary officer of the state, has been detailed for temporary duty at the maneuvers on the Mexican frontier.——Dr. and Mrs. Maurice L. Blatt sailed for Europe, April 27.

INDIANA

Health Officers to Meet.—Dr. John N. Hurty, Indianapolis, secretary of the State Board of Health, has issued summonses to all the county health commissioners in the state to attend the annual conference to be held at the Claypool Hotel, Indianapolis, May 9 and 10.

District Society Meeting.—The annual meeting of the Twelfth District Medical Society was held in Fort Wayne, April 12, and the following officers were elected: Dr. William F. Shumaker, Butler, president; Drs. Benjamin P. Weaver, Fort Wayne, and Lyman T. Rawles, Huntertown, vice-presidents; and Dr. Homer E. Glock, Fort Wayne, secretary-treasurer.

Personal.—Dr. Joseph Kentling, Smithville, while crossing the Monon tracks, was struck by a train but only slightly injured.——Dr. Philip E. Stockhardt, Elwood, has been adjudged of unsound mind and committed to the Eastern State Hospital, Richmond.——Dr. Lewis C. Griffith, Bowling Green, has been appointed health officer of Washington Township, vice Dr. T. Roy Cook, Bowling Green.——Dr. and Mrs. Thomas J. Bowles, Muncie, celebrated their golden wedding anniversary, April 14.

MARYLAND

Hospital Made Residuary Legatee.—By the will of the late Benjamin F. Chambers of Trenton, N. J., formerly of Cecil County, Union Hospital of Cecil County, Elkton, is made the residuary legatee and will receive about $60,000.

Decide on Jarrett Portrait.—At a meeting of the Baltimore County Medical Association, held in Towson, April 19, it was decided to have a portrait painted of Dr. James H. Jarrett, Towson, who graduated fifty-nine years ago, the portrait to be deposited with the Medical and Chirurgical Faculty of Maryland in Baltimore.

Annual Meeting of Society.—At the annual meeting of the Montgomery County Medical Society, April 20, the following officers were elected: President, Dr. James Dudley Morgan, Chevy Chase; vice-president, Dr. Frederick N. Henderson, Rockville; secretary-treasurer, Dr. John L. Lewis, Bethesda; censors, Drs. William T. Pratt, Potomac; Clayborne H. Mannar, Rockville; Vernon H. Dyson, Laytonsville, and delegate to the Medical and Chirurgical Faculty of Maryland, Dr. James E. Deets, Clarksburg.

State Sanatorium Report.—The fourth annual report of the Maryland Tuberculosis Sanatorium, founded in 1906, and located on the crest of the Blue Ridge Mountains, sixty-nine miles northwest of Baltimore, and established at a cost of $265,000, for white citizens in the incipient stage of tuberculosis, shows that during the year 574 patients ranging from seven to seventy-two years of age, were treated, the daily cost per capita being 95.3 cents. The beds were filled at all times, and there was a waiting list of from four to fifty. More than 500 patients have had to be refused annually. During the year 371 were discharged, 17 or 4.6 per cent. apparently cured; in 142 or 38.3 per cent., the progress of the disease was arrested; in 153 or 41.2 per cent. the condition of the patient improved; in 54 cases or 14.6 per cent., the condition of the patient remained unimproved; and 5 patients or 1.3 per cent. died. Of the patients, 102 remained less than ninety days, and 269 for a longer period. The after results in the case of 618 patients discharged since the opening of the institution in August, 1908, show that 36 are well, 271 are living and working; 173 are living and not working; 106 have died and the condition of 32 is unknown.

Baltimore

Personal.—Dr. Samuel C. Chew is suffering from a severe attack of influenza.——Dr. Jacob D. Norris, president of the board of police examiners, is seriously ill with heart disease.——Dr. Mary Sherwood has been elected president and Dr. Florence R. Sabin, corresponding secretary of the Just Government League.

Home for Physicians' Widows and Orphans.—At the second annual meeting of the board of managers of the Home for Widows and Orphans of Physicians, held April 18, the following officers were elected: president, Mrs. Eugene F. Cordell; vice-president, Mrs. Sophia Cooke Waters; recording secretary, Mrs. Augusta E. Fenton; corresponding secretary, Mrs. John G. Jeffers, and treasurer, Dr. Eugene F. Cordell.

MICHIGAN

Personal.—Dr. David J. Levy, Kalamazoo, has returned from Vienna.——Dr. Arthur R. Hayton, Shelby, suffered severe injuries of the face by an explosion of chemicals in his office recently.——Dr. Collins H. Johnston, Grand Rapids, has sailed for Europe.

State Board Nominations.—The governor sent the following nominations to the state senate, April 19, for places on the State Board of Registration in Medicine: Dr. Henry C. Maynard, Hartford, to succeed himself; Dr. Arthur M. Hume, Owosso, to succeed Dr. Flemming Carrow, Detroit; Dr. Bret Nottingham, Lansing, to succeed himself; Dr. Joseph A. Crowell, Iron Mountain, to succeed Dr. Theodore A. Felch, Ishpeming; and Dr. Austin W. Alvord, Battle Creek, to succeed himself.——Prof. Robert L. Dixon, Ann Arbor, has been nominated by the governor to succeed Dr. Frank W. Shumway, Lansing, as secretary of the State Board of Health.

Antituberculosis Work.—At the annual meeting of the Kalamazoo Antituberculosis Society, March 29, Dr. Herman Ostrander was elected president; Dr. John B. Jackson, secretary; and Dr. S. Rudolph Light, treasurer.——The Detroit Tuberculosis Sanatorium has received an anonymous gift of $5,000, which will provide for the perpetual endowment of one bed in the institution.——The Saginaw Antituberculosis Association has filed articles of incorporation.——Morgan Heights Sanatorium, the Marquette County Tuberculosis Hospital, situated about 7 miles west of Marquette on a high plateau, is practically completed and will be ready to receive patients in a few days.

Certified Milk Bill Passed.—After two years' effort, opposed by money dairymen who were selling milk which was not certified but which was claimed to be certified, the legislature has just passed a bill limiting the term certified milk to the high standard required by the committee appointed by the State Medical Society. This committee is composed of Drs. Collins H. Johnston, Grand Rapids; Marinus L. Holm, state bacteriologist, Lansing; Blanche N. Epler, Kalamazoo; Christopher G. Parnall, Jackson, and Thomas B. Cooley, Detroit. The bill was practically the same as the New Jersey law, except as to the method of selecting the commissioners who are now to be appointed by the local health boards if they have two physicians as members, otherwise by the state board. The bill "provides for the appointment and incorporation of medical milk commissions and the certification of milk produced under their supervision," and details the requirements.

MISSISSIPPI

Health Exhibit Campaign.—Dr. Waller S. Leathers, University, director of the public health and sanitation campaign of the State Board of Health, has received a letter from the Queen and Crescent System offering the board the use of two cars for the use of the health exhibit campaign throughout the state. Plans for the trip of the cars through Mississippi are now being formulated.

State Medical Society Meeting.—The annual meeting of the Mississippi State Medical Association was held in Jackson, April 11-13, under the presidency of Dr. John W. Young, Grenada, and the following officers were elected: president, Dr. Daniel J. Williams, Ellisville; vice-presidents, Drs. John T. Longino, Jonestown; Samuel E. Eason, New Albany, and John C. McNair, Fayette; secretary, Ewing F. Howard, Vicksburg; treasurer, Dr. Levi B. Sparkman, Cleveland; councilors, Drs. Sydney W. Johnston, Vicksburg; Charles M. Coker, Eden, and G. W. Wallace, Arbo. The association nominated the following five members as members of the State Board of Health to be appointed by the governor in 1912: Drs. John Darrington, Yazoo City; Giles S. Bryan, Amery; Elbert A. Cheek, Arcola; Theophilus E. Ross, Hattiesburg, and Inman W. Cooper, Newton. All of the nominees are members of the present state board.

NEW YORK

Personal.—Dr. Montgomery E. Leary has resigned as director of the Rochester Public Health Association after thirteen years' service. Dr. Leary will hereafter give his entire attention to his duties as superintendent of the Iola Sanitarium.——Dr. David H. MacKenzie, Millbrook, is reported to be seriously ill with disease of the gall-bladder in Sadlier Hospital, Poughkeepsie.

Hospital Gifts for Troy.—The Board of Directors of the Samaritan Hospital has received an offer from Miss Alida Van Schoonhoven of that city to erect and equip a memorial hospital.——George B. and Robert Cluett have also offered to erect and equip a new fireproof hospital complete. It is estimated that the two offers will involve the expenditure of more than $300,000.

Urges Restoration of Medical Library.—Albany County Medical Society, at its meeting, April 12, adopted a resolution calling the attention of the legislature to the great loss sustained in the destruction of the medical division of the New York State Library, when a section of the State Capitol was destroyed by fire recently, and asking that steps be taken to restore the library.

Approves Medical Experimentation.—The house of delegates of the Medical Society of the State of New York, on April 17, adopted a resolution declaring "that animal experimentation in this state is conducted in a proper and merciful manner, and that such experimentation is positively essential in medical progress; that unmerciful experimentation is not practiced in this state, and is prohibited by law," and opposing the bill which provides for a commission to investigate the practice of vivisection, on the ground that it is unnecessary and mischievous and calculated to hinder and cripple experimentation.

State Medical Society Meeting.—At the annual meeting of the Medical Society of the State of New York, held in Albany, April 18-20, the following officers were elected: president, Dr. Wendell C. Phillips, New York City; vice-presidents, Drs. Peter W. Van Peyma, Buffalo; William F. Campbell, Brooklyn, and Clifford. R. Hervey, Oswego; chairman of the committee on scientific work, Dr. Louis Neumann, New York City; chairman of the committee on legislation, Dr. Elliott T. Bush, Horseheads; chairman of the committee on arrangement, Dr. William J. Nellis, Albany; chairman of the committee on public health, Dr. Joshua M. Van Cott, Brooklyn; secretary, Dr. Wisner R. Townsend, New York City (reelected); treasurer, Dr. Alexander Lambert, New York City; delegates to the American Medical Association, Drs. Algernon T. Bristow, Brooklyn; James W. Fleming, Brooklyn; Edward W. Mulligan, Rochester; Henry L. Elsner, Syracuse; Edgar A. Vanderveer, Albany, and Edward E. Cornwall, Brooklyn.

New York City

Mount Sinai Hospital Purchases Property.—This institution has purchased two flat buildings in East Ninety-Ninth Street for the site of the proposed pathologic building made possible by the donation of $200,000 by Adolph Lewisohn.

More Meningitis Comes From Greece.—The Greek steamship *Athinai* brought to this port three more cases of cerebrospinal meningitis, making a total of thirty-five cases brought here from Greek ports within two months. There have been eighty cases detained at Quarantine this year with a mortality of 35 per cent.

Preparing to Fight Poliomyelitis.—Several physicians have prophesied an outbreak of infantile paralysis with the advent of warm weather. The health board is preparing to grapple with the disease as it has not done before. Hitherto the law has provided only for the reporting of cases, but if the virulence of the disease seems to warrant the action, the board of health will take charge of it. Two cases have been reported in the Bronx and six in Brooklyn since March 1.

Personal.—Drs. Henry Clarke Coe and Samuel M. Brickner, who were operated on recently for appendicitis, are convalescent.——Dr. William L. Russell, superintendent of the Long Island State Hospital, and for a number of years medical inspector of the New York State Commission in Lunacy, has been elected by the board of governors of New York Hospitals superintendent of the Bloomingdale Hospital, White Plains, vice Dr. Samuel B. Lyon, who will retire July 1 after twenty-five years' service.

Buffalo

Personal.—Dr. Charles S. Meahl has been appointed sanitary expert to the department of health.——Dr. Earl P. Lothrop has returned after a winter in Florida.

City Hospital Site Selected.—The aldermen have voted that the city purchase the West Farm site containing 81 acres for the proposed city general hospital for $225,000. The site has 1,500 feet frontage on Delevan Avenue, and 2,800 feet on Grider Street.

Higher Requirements.—On April 10 the new pathologic and chemical laboratories of the University of Buffalo were inspected by the Erie County Medical Society. The regular meeting of the society was held at the medical school. At the suggestion of the faculty of the medical school, a resolution was passed, recommending that the Medical Society of the State of New York urge that one year of college work be required of medical students for entrance, and a fifth year in a hospital of all graduates.

NORTH DAKOTA

State Association Meeting.—The annual meeting of the North Dakota State Medical Association will be held in Fargo, May 9 and 10.

Personal.—Dr. Archibald L. McDonald, Grand Forks, professor of anatomy in the University of North Dakota College of Medicine, will, it is reported, sever his connection with the institution at the close of the present year and will devote his entire attention to private practice. He will still be a special lecturer on the medical faculty.——Dr. Roy W. Pense has been appointed health officer of Minot.——Dr. F. A. Bordwell, Marmath, was seriously injured in a runaway accident near that place, April 17.——Dr. William C. Eichler, Underwood, has gone to Europe.

PENNSYLVANIA

Personal.—Dr. Charles H. Mann, president of the Bridgeport Board of Health, was recently injured in an automobile accident.——Drs. W. F. Krick of Philadelphia, a graduate of University of Pennsylvania; John J. Sosnowoski, of Mahanoy City, Jefferson Medical College; and Ward J. Brinton, Philadelphia, Jefferson Medical College, have been elected resident physicians of St. Joseph's Hospital, Reading.

Sanatorium Report.—Out of a total of 3,649 cases of tuberculosis, treated at Mount Alto Sanatorium for eighteen months, those in the moderately advanced stage of the disease number 1,382, and in the far advanced stage, 1,803, according to the report just issued. During this period out of 636 moderately advanced cases, discharged from the institution, 134 had the disease arrested and 375 were much improved. In the far advanced cases, 67 out of 780 had been greatly improved with the disease arrested, and 387 showed marked general improvement.

Philadelphia

New Hospital Society.—The physicians connected with the Jewish Hospital, have recently formed a clinical society and elected the following officers: president, Dr. Max H. Bochroch; vice-president, Dr. Jay C. Knipe; secretary and treasurer, Dr. Nate Ginsburg, and recorder, Dr. David Kapp.

Campaign Against Flies.—The public health committee of the Civic Club together with the health authorities will begin a crusade against flies and other harmful insects. Drs. James J. Bradley, Jr., Collin Foulkrod, Elizabeth Snyder and Edith E. Eayre will lecture in the settlement houses throughout the city, and the authorities will require all foodstuffs, such as meat, vegetables and milk, be properly screened and that all butchers and grocers keep their wares from infection from flies.

Gastroenterologists Meet.—The fourteenth annual meeting of the American Gastroenterological Association was held in Philadelphia, April 19-20. The following officers were elected: president, Dr. Walter B. Cannon of Boston; vice-presidents, Drs. John A. Lichty, Pittsburg, and William G. Morgan, Washington, D. C.; secretary and treasurer, Dr. Franklin W. White, Boston, and members of the council, Drs. Samuel J. Meltzer, New York; Charles D. Aaron, Detroit, and Julius Friedenwald, Baltimore.

Personal.—Dr. Jacques Loeb, of the Rockefeller Institute for Medical Research, delivered the address at the annual conversational meeting of the Pathological Society, April 27 His subject was "Fertilizing Effects of the Extracts of Tissues, Blood and Sperm." After the address a reception was given for Dr. Loeb at the University Club.——Prof. Svante Arrhenius, Stockholm, Sweden, will deliver the third Wei Mitchell Lecture of the College of Physicians in Mitchell Hall on May 16. The subject will be "The Passage of Micro organisms Through Interstellar Space: a Theory Bearing on the Origin of Life on a Planet."—Dr. Joseph S. Neff, director of public health and charities, has recovered and returned to his duties at city hall on April 18.——Professor Hugh Campbell Ross, director of research at the Royal Southern Hospital at Liverpool, and honorary clinical pathologist at the Royal Liverpool County Hospital for Children, will give a course of lectures during the coming month at Jefferson Medical College for the purpose of demonstrating new discoveries in the treatment of cancer.

SOUTH CAROLINA

County Association Meeting.—Edgefield County Medical Association held its annual meeting in Edgefield, March 29. Dr. John T. Hunter, Trenton, was elected president; Dr. George L. Walker, Johnston, vice-president, and Dr. John G. Edwards, Edgefield, secretary-treasurer.

Personal.—Dr. Charles F. Williams, Columbia, state health officer, has resigned, but the executive committee of the State Board has refused to consider the resignation.——Dr. John Cantzon Foster has been elected a member of the board of health and health officer of Lancaster.

State Society Meeting.—The South Carolina Medical Association held its sixty-third annual meeting in Charleston, April 18-20, under the presidency of Dr. James H. McIntosh, Columbia. The principal address was delivered by Drs. Alexander Lambert, New York City, and Judson Daland, Philadelphia. Columbia was selected as next place of meeting. The following officers were elected: president, Dr. J. Wilkinson Jervey, Greeneville; vice-presidents, Drs. Archibald E. Baker, Charleston; John H. Miller, Cross Hill, and Henry B. Lee, Summerville; secretary, Dr. Eagar A. Hines, Seneca (reelected); treasurer, Dr. Charles P. Aimar, Charleston (reelected); councilors, Drs. J. Taliaferro Taylor, Adams Run (reelected); Gottlob A. Neuffer, Abbeville, and Julius A. Faison, Bennettsville; and editor of the *Journal of the South Carolina Medical Association*, Dr. Julius C. Sosnowski, Charleston (reelected).

SOUTH DAKOTA

Personal.—Drs. Charles E. McCauley, Aberdeen, and William Lowe, Madison, have been appointed members of the State Board of Medical Examiners to succeed Drs. H. F. Bright, White Lake, and Alonzo A. Cotton, Vermilion.——G. G. Redfield, Rapid City, has been appointed a member of the State Board of Osteopathic Examiners, and Dr. Robert T. Dott, Salem, a member of the State Board of Health.——Dr. and Mrs. Frank I. Putnam, Sioux Falls, have returned from abroad.

District Society Meeting.—The Eighth (Yankton) District Medical Society held an interesting meeting at the State Health Laboratory, Vermilion, March 28, followed by a banquet furnished by the physicians of the city. The program included papers on "Infection and Immunity," by Dr. Harley E. French, Vermilion; "Present Status of Serum Therapy," by Dr. Philip R. Burkland, Vermilion; "Practical Use of Autogenous Vaccines," by Dr. Edward W. Meis, Sioux City, Ia.; "Practical Laboratory Methods in the Diagnosis and Treatment of Infectious Diseases," by Dr. Mortimer Herzberg, Vermilion; and "Hypodermic Medication in Specific Disease," by Dr. S. H. Richman, Yankton. The next meeting will be held in Pierre June 15-17.

TEXAS

Sanitary Code Prosecution.—The first prosecution under the new sanitary code law of the department of health is to be held at Waco. The alleged offender in the case is the registrar of vital statistics at Mart.

State Association Meeting.—The annual meeting of the State Medical Association of Texas will be held at Amarillo, May 9-11. One feature of the entertainment will be a barbecue and out-door feast at Palo Duro Canyon.

County Society Election.—At the annual meeting of Titus County Medical Society, held in Mount Pleasant, March 23, Dr. Albert A. Smith, Goolesboro, was elected president, and Dr. William H. Blythe, Mount Pleasant, secretary.

Tents for Tuberculosis Patients.—The board of health of Dallas has approved the plan of the local Red Cross for the erection of six tents on the city hospital grounds for the isolation and care of tuberculosis patients in the City Hospital, and the tents will be erected under the direction of city health officer, Dr. Thomas B. Fisher.

Northeast Texas Physicians Meet.—At the annual meeting of the Northeast Texas District Medical Association, held in Fort Worth, April 11 and 12, Dr. Joseph H. McCracken, Mineral Wells, was elected president; Dr. John H. McLean, Fort Worth, vice-president, and Dr. A. D. Patillo, Petrolia, secretary. The next meeting will be held at Mineral Wells.

Leprosarium.—It is announced that the state home for lepers provided for by an act of the thirty-first legislature will be established by Governor Colquitt. Dr. Manton M. Carrick has been appointed superintendent and a commission of three men, including the state health officer to be one, will be appointed immediately to locate the institution. An appropriation of $40,000 was made by the legislature for the purpose of establishing the institution and maintaining it until August 31.

UTAH

Resolutions Regarding Dr. Carnahan.—Weber County Medical Society, at its regular meeting, April 19, adopted resolutions setting forth the high and honorable work done by the late Dr. John D. Carnahan, Ogden, a member of the society, presenting a sketch of his life and deploring his death.

Amendment to Medical Practice Act.—Utah has just secured legislation providing important amendments to its medical practice act. Among other things, the new act provides for higher standards of preliminary education, revocation of licenses for unprofessional conduct and a better definition of the practice of medicine.

VERMONT

Drinking Cups Prohibited.—The first quarterly bulletin of the State Board of Health for the year contains a copy of the regulations adopted by the board, prohibiting the use of the common drinking cup in all public places, parks, fountains, school houses, factories, mills, workshops, libraries, public halls or other public buildings, railroad stations and railroad trains on and after May 1.

VIRGINIA

New Hospitals.—Drs. Robert C. Bryan and H. Stuart MacLean have approved plans for a hospital to be built at Grace and Monroe streets, Richmond, to cost about $60,000.——Dr. J. Shelton Horsley, Richmond, has under consideration plans for a private hospital to be erected at Pine and Grace streets.

Personal.—Dr. William A. Deas, Richmond, has resigned as physician to the Lee Camp Soldiers' Home.——Dr. George T. Myers, Norfolk, has been appointed medical assistant in the health department.——Dr. John J. Lloyd, Jr., Lynchburg, has succeeded Dr. W. E. Jennings as assistant resident physician at Catawba Sanatorium.——Dr. Clarence W. Cowper, Norfolk, appointed medical inspector of the health department, has resigned as alderman of that city.——Dr. Thomas F. Keen, Hamilton, announces his retirement from active practice.

WISCONSIN

Medical Press Board.—At a meeting of the Milwaukee County Medical Association, April 14, a board of censors, otherwise known as a press committee, was appointed, whose duty is to supervise, so far as possible, all articles appearing in the lay press relative to the medical profession or dealing with medical subjects.

Contagion and Eddyism.—The Milwaukee County Medical Society appointed a committee at a special meeting, April 16, "to investigate the attitude of the Christian Science church toward the practice of medicine with especial reference to the treatment of contagious diseases." It was reported that there were, on that day, fifty-three cases of scarlet fever in one ward of the city being treated by Eddyist healers.

Antituberculosis Society Meeting.—The new Wisconsin Antituberculosis Association held its meeting in Milwaukee, April 11, and elected officers. Dr. Harry Greenberg, Milwaukee, was elected chief of the medical staff. A fresh-air camp for tuberculous convalescents will be established on the Kern tract, the use of which has been given the society by the park board. Tents accommodating two patients each will be erected, and the camp will be known as the Social Workers' Tuberculosis Sanatorium.

Personal.—Dr. Clinton H. Lewis, Bayview, Milwaukee, sustained serious injuries of the head and back in a runaway accident, April 17.——Dr. Bernard C. Gudden was guest of honor at a banquet given by the Oshkosh Medical Club, April 14, in commemoration of the thirtieth anniversary of Dr. Gudden's entrance into practice of medicine in Oshkosh.——Dr. Richard J. Muenzner, Allenton, has been elected secretary of the American Medical Association of Vienna.——Dr. Charles R. Bardeen has been reelected president of the board of directors of the Madison General Hospital Association.——Dr. John M. Dodd has been elected mayor of Ashland.——Dr. James V. Canavan has been elected mayor of Appleton.

GENERAL NEWS

Confederate Surgeons to Meet.—The Association of Medical Officers of the Army and Navy of the Confederacy will hold its annual meeting at Little Rock, Ark., May 16-18, at the same time as the reunion of the United Confederate Veterans. Dr. Edwin D. Newton, Atlanta, Ga., is president, and Dr. A. A. Lyon, Nashville, Tenn., secretary of the association.

Therapeutic Program.—The twelfth annual meeting of the American Therapeutic Society will be held in Building "B," Harvard Medical School, Boston, May 11-13, under the presidency of Dr. Harvey W. Wiley, Washington, D. C. The subject of the presidential address will be "Bromato-Therapy," and the scientific program shows twenty-nine titles. The annual dinner will be given at the Hotel Vendome on the evening of May 12.

Travel Study Group.—Dr. Johannes Nietner, secretary of the permanent International Commission on Congresses of Hygiene and Demography, and secretary-general of the fourteenth congress, announces that a group of German physicians is planning a study tour in the United States in the summer of 1912 in connection with their visit to the coming congress, and that for the final arrangements, the group will send a representative to the United States in the autumn of this year.

Manila Physicians Meet.—The annual meeting of the Manila Medical Society was held in the Philippine General Hospital, January 9. The following officers were elected: president, Major Weston P. Chamberlain, M. C., U. S. Army; vice-president, Dr. Robert E. L. Newberne; editor, Dr. William E. Musgrave; acting editor, Dr. Vernon L. Andrews; secretary and associate editor, Dr. F. B. Bowman; treasurer and business manager, Dr. Harry D. Kneedler, and councilors, Drs. Musgrave and Andrews.

Alumni Meeting.—The annual dinner of the New England Alumni Association of the University of Vermont was held in Boston recently and was attended by about seventy-five alumni. Dr. Walter D. Williamson, Portland, Me., was toastmaster. The following alumni of the medical department were elected officers: president, Dr. Walter D. Williamson, Portland, Me.; vice-presidents, Drs. Frank W. Page, Boston, and Frank H. Clapp, North Grafton, Mass., and member of executive committee, Dr. C. Parker Holt, Cambridge, Mass.

Society of Tropical Medicine.—The eighth annual meeting of the American Society of Tropical Medicine will be held in Tulane University, New Orleans, May 18 and 19, under the presidency of Dr. William S. Thayer, Baltimore. The first scientific session will be devoted to papers on malaria, the afternoon session to leprosy and sprue. The morning session of the second day will be occupied by general discussion on amebiasis, and the afternoon to election of officers and papers on pellagra, yellow fever and miscellaneous subjects.

Alcohol and Drug Habits Studied.—The American Society for the Study of Alcohol and Other Narcotics held its fortieth annual meeting in Baltimore, April 19 and 20. The principal address was delivered by Dr. Winfield S. Hall, Chicago, on "Biological and Physiological Relations of Alcohol." The following officers were elected: president, Dr. Winfield S. Hall, Chicago; vice-president, Dr. Lewis D. Mason, Brooklyn; corresponding secretary and treasurer, Dr. Thomas D. Crothers, Hartford, Conn.; recording secretary, Dr. G. H. Benton, Doublinggap, Pa., and member of the executive committee, Dr. Thomas A. MacNicholl, New York City. Resolutions were adopted asking the government to use its influence to prevent the sale of opium in China.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, April 8, 1911.

A Public Health Museum

The National League for Physical Education and Improvement has proposed that the London memorial to the late King Edward, whose great interest in sanitary problems is well known, should take the form of a public health museum. In a recent conference of health-promoting institutions, a discussion on the need of coordination disclosed the existence of over eighty such national agencies in London and of a large number of local agencies in London and throughout the country. It was shown that these suffered much both in finance and work from overlapping, from separation of offices and staff, and from lack of coordination. The striking success of the tuberculosis exhibition opened in Dublin and then transferred to the Irish Village in the exhibition at London and to other places throughout the country, demonstrated the great interest taken by the public in sanitary questions. It is proposed to erect a popular museum which should accommodate a permanent collection and also furnish duplicate material for the equipment of traveling vans. It should be a model in constant and close relation with provincial museums to which it would probably give birth. It might also become a loan center for the distribution of replicas of its models and diagrams for circulation among schools and institutions. The building should also form a nucleus for the coordination of the various health-promoting institutions, both metropolitan and national. For this purpose, it should include the following: Two or three meeting halls of different sizes, ten or twelve committee rooms, central offices, a library and reading rooms, lecture rooms, workshop and draftsman's room. The cost of maintenance would be met, to some extent, by the rental of suites of offices, halls, committee rooms, especially by health-promoting conferences and institutions, and to some extent by small fees for courses of instruction. In the main, however, instruction must be given at a low cost, fees being charged only when they will guarantee greater interest in those who pay, and being reduced to such a level as will admit of the greatest possible use of the facilities provided. This would be sufficient grounds for appealing for subscriptions to trades unions, friendly societies, insurance companies and the general public. An appeal will be made for a memorial sum of $500,000 and a subscription of $25,000 a year as a minimum. The early co-operation of organizations of the working classes and of those working for the prevention of tuberculosis and alcoholism will be sought.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, April 14, 1911.

The Wassermann Reaction as a Means of Detecting Latent Syphilis

At a recent session of the Académie de médecine, Drs. Letulle and Bergeron read a paper based on the investigation of the Wassermann reaction in ninety patients affected with chronic diseases. There were thirty-nine positive reactions. This was to be expected among a large number of these where the patients were paraplegic and subjects of aortic lesions. Moreover, a positive reaction was obtained in subjects of chronic nephritis, non-tuberculous pulmonary diseases, cerebral or meningeal hemorrhages, etc. Among cases which came to autopsy (twelve) the existence of old or recent syphilitic lesions was ascertained.

The conclusion is that an almost absolute diagnostic value should be given to a positive Wassermann reaction; a negative reaction, however, does not prove that there is no syphilis.

Insufficiency of the Means Employed to Prevent a Drug from Dissolving in the Stomach

On April 7 Dr. Linossier of Vichy called the attention of the Association médicale des hôpitaux de Paris to a practical point of current therapeutics. To preserve a drug (pancreatin for example) which is soluble in gastric juice from contact with this liquid, as well as to avoid the irritating action of certain substances like potassium iodid on the stomach walls, it is customary to enclose these substances in an envelope which is not affected by the gastric juice; and it is supposed that the contents escape only when the envelope is digested by the pancreatic juice. These envelopes, which are usually made of gluten, keratin, or formalinized gelatin, are used to ascertain the strength of the pancreatic secretion. Now, while these envelopes resist the gastric juice, it is very easy to show that the soluble substances enclosed in them pass out by osmose from the time the capsule is swallowed, that is, very rapidly. On plunging commercial capsules of potassium iodid with keratinous or glutinous coating into gastric juice, or even into water, Dr. Linossier has seen reactions of iodin in the surrounding liquid appear in less than a minute. The use of such capsules to protect soluble substances from gastric juice is then altogether unsatisfactory. They may, however, protect an insoluble substance.

Prizes of the Society of Infant Hygiene

The Société d'hygiène de l'enfance has offered a prize for a paper on the following question: *Les cantines scolaires, leur utilité; que doivent-elles être?* (Public provision of lunches for school children: their utility; what ought they to be?). The manuscripts should be received before Dec. 31, 1911. They should be unpublished, written in French, German, English, Italian or Spanish. They should not be signed but each should bear a device or superscription reproduced on a sealed envelope containing the name and address of the author. The society reserves the right to draw from the best work materials for a pamphlet for propaganda and instruction. The papers should be addressed to the Président de la Société d'hygiène de l'enfance, 10, rue Saint-Antoine, Paris.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, April 7, 1911.

Personal

Prof. v. Eicken of Giessen has been appointed regular professor of otology, laryngology and rhinology. This is another instance, in a Prussian University, where a full professorship has been established to take the place of a special lectureship (*Extraordinariat*).

The Cremation Bill

As was to be expected and as I predicted, the bill for the permission of cremation was rejected by the committee of parliament, the vote being a tie. The eventual passage of the bill by a committee of the whole, in the house of delegates, is scarcely probable. owing to the lively objection of the center and conservatives, "the opposition."

Prolongation of Life

Professor Rahts of the imperial statistical office spoke March 24 before the society for insurance science on the prolongation of life, comparing the mortality of the German population with that of other civilized countries. Since 1871 the number of deaths in Germany has remained nearly constant, amounting to about 1,200,000 annually, although the population has risen from 41,000,000 to 65,000,000. The death-rate for 1871 was 30.6 per 1,000, that for 1909, only 18, a very marked reduction.

The estimation of the death-rate is fallacious, however, in comparing various cities of town and country. One must go back to the figures for the single age periods if he wishes to avoid mistakes in determining a relative death-rate. But this concerns only an ideal group of the population who have been subjected through their whole life to the mortality conditions that prevail in each decade. The average duration of life then shows how many years these groups of individuals have lived. Examination of the curves shows that the minimum and the maximum have not behaved in the same manner, but the minimum has sunk and the maximum risen, so that the mortality under 48 has become less, while that above 48 has grown larger. The typical duration of life in Germany is 71 years in men, 73 in women (in Norway 78 years), so that the saying of the psalmist, "The days of our years are three score years and ten." Psalm xc, still holds true. While this increase in the length of life is gratifying, it is in accord with that in other civilized countries, for in Sweden it has increased ten years, in Belgium and Holland 5, in England 3, in France 4, while only in Italy and Austria do the figures show only a trifling advance. If a comparison in percentages be made the figures for Germany are more favorable, showing an increase of 9.1 per cent. against 1.1 per cent in England. The reason for the slighter rise in Germany is the large infant mortality.

The average length of life is often taken as an index for the productive power of a people, but this is not quite correct because infants and the aged are included. Rahts has calculated the average for the productive period of life from 16 to 60 years and has shown that for this class the average length of life has increased one and three-fourths years from 1870 to 1900. As 1,200,000 enter their sixteenth year annually, this increase means an addition of 2,000,000 years of labor for the community, a gain that is largely due to the social legislation and the improvement in hygiene, so that these measures richly pay for the expense involved. Rahts then proceeds to consider the significance of the corrected figures and asserts that a population in vigorous growth gives different figures than a stationary population. The average duration of life is not sufficient to give a correct picture of the mortality rate, but it is necessary to have an estimate of the death liability. The vitality of a people reckoned from this figure shows how many are living for one death. Rahts reaches the conclusion that it has increased in every age class, rising rapidly in men and sinking again rapidly, while in women the curve is more gradual. This agrees with the results of observations by the medical school inspectors who have found that girls are more frail.

The curve of death liability in men follows a peculiar course: after a fall up to the thirteenth year there ensues a rise to the twenty-first, after which it remains stationary a few years and then rises again. As this peculiarity is found in France as well as in Germany, while in England the stationary period does not occur, it is probable that this stationary period is attributable to the salutary influence of enforced military service in France and Germany. If deaths from tuberculosis are excluded, the curve loses its peculiar character and becomes similar to that in women, so that it is possible also that the differing effect of tuberculosis on the two sexes is responsible.

The Census

According to the current data of the last census taken in 1910 the entire population of Germany was 64,896,881, an increase over the last census in 1905 of 4,255,603 (7.02 per cent.), which means a yearly increase for the German empire of 800,000. It is notable that there is a decrease in the excess of females in Germany. While in 1906 there were still 1,500,000 more women than men, in 1909 only 1,000,000 more women could be found and the census of 1910 shows an excess of females amounting to only 800,000.

VIENNA LETTER.

(From Our Regular Correspondent)

Vienna, April 1, 1911.

Statistics About Practitioners in Austria.

The official figures dealing with our profession are now accessible and their perusal affords a good insight into the prospects of the medical career in this country. The number of inhabitants at the end of 1910 was 28,000,000 in the Austrian part of the empire, which forms the subject of the official report. There were 13,202 licensed duly qualified medical men practicing, including about 1,250 military doctors who were compelled to do private practice also because there was no other doctor living in the district—which fact illustrates the paucity of doctors in some places. Since 1905 the population has increased by 4 per cent. and the number of practitioners by over 6 per cent. In the report the year 1887, when the present overproduction of doctors commenced, is taken as basis. The number of doctors has increased since that year by 76 per cent., but the population has increased only a little less than 30 per cent. At that time, the ratio of distribution of doctors was 1 for each 3,242 of the population. Now it is one doctor for 2,175. The highest increase was in the largest cities while in the country there is at present still a decided scarcity of medical men. The increase of doctors is also well illustrated by the figures concerning university pursuits of students. In 1887 the proportion of medical students was 30 per cent. of all university students; in 1895 it was over 40 per cent. The output of doctors by graduation was 5,075 from 1887 till 1895; from 1896 to 1905 it was 7,225. At the same time, however, the number of doctors who settled down and were practicing had increased by 4,500 only, indicating, either that the annual mortality of doctors, which is computed at 18 per cent., is much higher than calculated or, what is more likely, that a large number of graduated doctors preferred to give up the fight for a practice and either emigrated or turned to another occupation.

Hand in hand with the absolute increase of doctors, who do not see their way to live outside of the great towns, specialization has been favored in a very high degree with us. There are, for instance, 475 specialists in Vienna, and 200 in Prague, or in Vienna 16 per cent. of the doctors, in Prague over 25 per cent. have become specialists. These towns, however, are also university towns, where specialists are very frequent for obvious reasons. A large number of doctors practice in health resorts where they have only a season practice. In Karlsbad there are 163, in Meran 76, in Baden 53, in Marienbad 69, in Bozen 37 and Abbazia 36 doctors who live there for only part of the year. The number of these part-time practitioners has increased within five years by 18 per cent. Quite different are the figures pertaining to the local and territorial distribution of doctors. While in certain cities the proportion is exceedingly high, in the country districts the scarcity is alarming. For instance, in Olmütz, a town of 60,000 inhabitants, there is one doctor for each 390 inhabitants. In Trieste we find one to 1,010, while Vienna has one to 610, and Prague one to 560. On the other side, in lower Austria (one of the most cultivated countries of the empire) the figure is one to 2,030, in Styria it is one to 3,075, while the lowest figures are in Galicia, one to 10,000 inhabitants. In these latter countries it is evident that the poverty of the population and the low standard of life deter an educated man from settling down, unless he comes from this stock. There is only one possibility of subsisting—appointments which will furnish a maintenance. The payments are not very high, 1,000-3,000 kronen ($200-$600) per annum. Nevertheless, there was a fairly large number of such appointments vacant for a period of longer than two years because no man was willing to accept the post. Altogether, about 60 per cent. of all doctors hold one or other appointment with the state, the government or the *Krankenkasse* (sick club); while the remainder are satisfied with a strictly private practice. The number of female practitioners in Austria is eighty; seven years ago it was only ten, and they have settled down in towns only. Three are practicing in health resorts, and sixteen have appointments with the sick clubs of the laborers (*Arbeiter Krankenkasse*) for the female members. Only thirty-two school doctors have been reported as such at the end of 1910.

In this country we have three large provident societies of doctors, membership being compulsory in none of them. The number of members is 1,080, 740 and 3,200 respectively, and they provide sick pay for their members, varying between $1 and $2 per day, as well as a sum equal to about one-half dollar per member in case of death, so that the widow or the dependents receive at once a few hundred dollars. Of course, there are besides other but smaller societies with similar aims.

The average age of the doctor obtaining an M.D. diploma in this country is 27½ years; the average expectation of life is 53 in the country, 55 in cities; which also illustrates the worse conditions prevailing in the country. It is also interesting to note that doctors are not very fertile, the average number of children of practitioners being two. The reasons will here too be found in the low standard of income of an average doctor.

Marriages

Frank L. Truitt, M.D., Indianapolis, to Miss Maide Zulich, at Indianapolis, April 25.

Herbert A. Thomas, M.D., Lima, O., to Miss Annabel Alling of Warren, O., March 15.

Roy Whittier Porteus, M.D., Chicago, to Miss Edith S. Wells of Evanston, April 18.

Elmer Lee Henderson, M.D., Louisville, Ky., to Miss Laura B. Owen of Austin, Minn., at Springfield, Ky., April 4.

Jacolyn Van Vliet Manning, M.D., Manhattan, New York City, and Christian Sofian Ernest Spoerl of Wilkes-Barre, Pa., in New York City, March 22.

Deaths

Charles Stedman Bull, M.D., a prominent ophthalmologist of New York City, died in the Presbyterian Hospital in that city, April 17, from valvular heart disease, aged 66. He was graduated from the College of Physicians and Surgeons, New York City, in 1868, and then studied in Europe for ten years, devoting himself especially to ophthalmology, otology, and pathology. He was a member of the American Medical Association, American Ophthalmological Society (of which he was president from 1903 to 1907), New York Academy of Medicine, and New York Ophthalmological Society. He was assistant surgeon to the Manhattan Eye and Ear Hospital from 1871 to 1873, assistant surgeon and surgeon to the New York Eye and Ear Infirmary since 1871, a member of the visiting staff of Charity Hospital from 1875 to 1880, and consulting ophthalmic surgeon to the Presbyterian, St. Luke's and St. Mary's hospitals. Since 1898, Dr. Bull had been professor of ophthalmology in the Medical Department of Cornell University. He made many contributions to the literature of his specialty.

Edmond Robillard, M.D. Laval University, Montreal, 1847; Nestor of the medical profession of Canada; died at his home in Montreal, January 13, from cerebral hemorrhage, aged 86. in Montreal, January 13, from cerebral hemorrhage, aged 86. In 1859 he was elected one of the governors and examiners of the College of Physicians and Surgeons of Canada, and from 1868 to 1874, he was registrar of the college. Bishop's College, Lennoxville, Que., conferred on Dr. Robillard, in 1873, the *ad eundem* degree of doctor of medicine. The honorary degree of master of surgery was also conferred on him by the Medical Faculty of Victoria College, Coburg, Ont., in 1881. He was for many years a member of the Canadian Medical Association, in 1882 its treasurer, and a year later, he was elected vice-president. He was also chief inspector of lunatics for the Province of Quebec and one of the assessors of Bishop's College. From 1884 to 1900, Dr. Robillard lived in Paris returning to Montreal in the latter year.

James Bell, M.D. McGill University, Montreal, 1877; a famous surgeon of Canada; died in the Royal Victoria Hospital, Montreal, April 11, from pneumonia, aged 58. Dr. Bell was probably the best known surgeon of the Dominion, and a man of sterling worth. After his graduation, he became house surgeon of the Montreal General Hospital, was promoted to medical superintendent in 1881, was made assistant surgeon on the staff in 1885, and surgeon in the following year. On his appointment in 1894 as surgeon in chief to the Royal Victoria Hospital, he was elected consulting surgeon to the Montreal General Hospital. He was a member of the British Medical Association, Canadian Medical Association, American Surgical Association and American Association of Genito-Urinary Surgeons. In 1888, Dr. Bell was appointed associate professor of clinical surgery in his alma mater, was made assistant professor of surgery and clinical surgery two years later, and professor of clinical surgery in 1894.

Henry Lyman Shaw, M.D. Harvard Medical School, 1859; for many years a member of the American Medical Association; a member of the Massachusetts Medical Society, American Ophthalmological Society, American Otological Society, and American Association for the Advancement of Science; a district physician of Boston for five years; a pioneer oculist and aurist of Boston; from 1861 to 1864, assistant surgeon, and from that time until 1892 surgeon to the Massachusetts Charitable Eye and Ear Infirmary, and then a member of its consulting staff; died at his home in Boston, April 2, aged 73.

Rickard Thomas Styll, M.D. Medical College of Virginia, Richmond, 1877; a member of the Medical Society of Virginia, and president of the Newport News Medical Society; physician in charge of the Richmond Small-Pox and Fever Hospital in 1881; and of the Pinel Hospital in 1885 and 1886; from 1887 to 1896, resident physician of the Hollins Institute, and from 1896 to 1899, first assistant at the Central State Hospital, Petersburg; died at his home in Newport News, April 1, from cerebral hemorrhage, aged 57.

Edward Patrick Stanley Hart, M.D. Long Island College Hospital, Brooklyn, 1897; a member of the American Medical Association; assistant visiting surgeon to St. Francis Hospital, Jersey City; surgeon to the North Jersey Street Railway Company and United Electric Company; captain and assistant surgeon N. G., N. J., assigned to the Second Battalion, Fourth Regiment; for a time connected with the health department; died at his home in Jersey City, April 10, from pneumonia, aged 38.

Robert Rae, M.D. New York University, New York City, 1858; a member of the Medical Society of the State of New York, and at one time president of the Wyoming County Medical Society; for several terms coroner of Wyoming County; assistant surgeon of the First New York Dragoons during the Civil War; a member of the local board of pension examining surgeons; died at his home in Portageville, April 1, from cirrhosis of the liver, aged 76.

James Robert Zearing, M.D. Rush Medical College, 1850; surgeon of the Fifty-Seventh Illinois Volunteer Infantry and later chief surgeon of the Fourth Division, Fifteenth Army Corps serving throughout the Civil War; said to have been the oldest alumnus of Rush Medical College; who had been blind for twenty-five years; died at his home in Chicago, April 16, from cerebral hemorrhage, aged 81.

Christopher Charlton Oliver, M.D. Atlanta (Ga.) Medical College, 1867; a member of the Medical Association of the State of Alabama; a Confederate veteran, and state senator in 1901; formerly surgeon general on the staff of the Fourth Brigade, Ala. Confederate Veterans; local surgeon to the Louisville and Nashville Railway; died at his home in Calera, March 22, aged 64.

John Jacob Koser, M.D. University of Pennsylvania, Philadelphia, 1881; a member of the American Medical Association; treasurer and once president of the Cumberland Valley Medical Association; local surgeon to the Philadelphia and Reading and Western Maryland Railways; chief burgess of Shippensburg, Pa.; died at his home, April 13, from angina pectoris, aged 53.

Richard W. Reasoner, M. D. Medical College of Ohio, Cincinnati, 1883; aged 50; formerly president of the board of health of Morrisonville, Ill.; for the last ten years a resident of Colorado Springs, Colo.; was shot and instantly killed in that city in an attempted holdup, April 14, in which, however, he mortally wounded his assailant.

William H. Clutter, M.D. Cincinnati College of Medicine and Surgery, 1868; a member of the American Medical Association; a veteran of the Civil War; superintendent of health of Oklahoma City and physician of Oklahoma County; a pioneer practitioner of Oklahoma; died at his home in Oklahoma City, April 12, aged 78.

Joel Gilbert Justin, M.D. University of Pennsylvania, Philadelphia, 1875; instructor in chemistry and professor of medical jurisprudence in Syracuse (N. Y.) University from 1886 to 1890; died at his home in Castile, N. Y., March 27, from bronchitis, after an invalidism of eight years due to cerebral hemorrhage, aged 59.

William McMillan, M.D. Starling Medical College, Columbus, O.; assistant surgeon of the Ninth Ohio Volunteer Cavalry and surgeon of the Fifth Ohio Volunteer Cavalry throughout the Civil War; since 1879 an attorney; died at his home in Massillon, O., February 12, from senile debility, aged 77.

Eugene E. Whitaker, M.D. Long Island College Hospital, Brooklyn, 1881; for several years health officer, village trustee and school director of Newport, Vt.; once president of the State Homeopathic Medical Society; died in a hospital in Montreal, March 25, after a surgical operation, aged 62.

John Henry Sanborn, M.D. Berkshire Medical College, Pittsfield, Mass., 1852; for fifteen years city physician of Newport, R. I.; a veteran of the Civil War, and acting assistant surgeon, U. S. Army, for about twenty years thereafter; died at his home in Newport, April 2, from senile debility, aged 75.

Henry S. Wright, M.D. Atlanta (Ga.) Medical College, 1893; a member of the American Medical Association; at one time professor of obstetrics in the International Medical Missionary College, Atlanta; died in a sanitarium in that city, April 9, from cerebral hemorrhage, aged 53.

Adoniram Judson Clark, M.D. Keokuk (Ia.) Medical College, 1892; a member of the American Medical Association; for twenty-eight years a practitioner of Nebraska, and for several years coroner of Boone County; died at his home in Albion, April 11, from pneumonia, aged 59.

Adoniram Judson Wakefield, M.D. Harvard Medical School, 1855; a member of the Florida Medical Association; a surgeon of volunteers during the Civil War, and since that time a practitioner of Jacksonville; died in that city, March 28, from senile debility, aged 87.

Frank E. Kitzmiller, M.D. Fort Wayne (Ind.) College of Medicine, 1879; of Piqua, O.; a member of the American Medical Association; special small-pox expert for the State Board of Health; and health officer of Piqua for fifteen years; died at his home, March 27, aged 61.

John Robinson Hoskins, M.D. Jefferson Medical College, 1905; a member of the American Medical Association; died at his home in West Chester, Pa., April 6, from cerebral abscess following a suppurative mastoiditis, consequent on an attack of influenza, aged 30.

Henry Krollpfeiffer, M.D. College of Physicians and Surgeons, New York City, 1875; a member of the Medical Society of the State of New York; president of the New York Liederkranz for three terms; died in the German Hospital, New York City, April 12, aged 62.

Frederick Birdseye Baker, M.D. University of Maryland, Baltimore, 1888; a member of the American Medical Association; and of the staff of the Norwalk (Conn.) Hospital; died at his home in East Norwalk, April 18, from cerebral hemorrhage, aged 55.

Reuben Harmon, M.D. University of Wooster, Cleveland, 1881; Western Reserve University, Cleveland, 1882; of Onowa; formerly a member of the Iowa State Medical Society; died in Denver, Colo., January 12, from the effects of a fall down stairs, aged 64.

Henry St. Clair Ash, M.D. Pennsylvania Medical College, Gettysburg, 1850; of Philadelphia; a member of the Medical Society of the State of Pennsylvania; died in St. Joseph's Hospital, Philadelphia, April 6, from cerebral hemorrhage, aged 85.

Louis B. Craig, M.D. Missouri Medical College, St. Louis, 1879; formerly a member of the American Medical Association; a member of the Missouri State Medical Association; died at his home in Salem, April 9, from pneumonia, aged 58.

David Smith Williams, M.D. University of Nashville, Tenn., 1858; said to have been the oldest practitioner of Texarkana, Ark.; a surgeon in the Confederate service throughout the Civil War; died at his home, March 23, from influenza, aged 75.

Emory B. Johns, M.D. Chicago Homeopathic Medical College, 1886; of Lexington, Ky.; was found dead in a hotel in that city, April 6, from the effects of a drug believed to have been self-administered with suicidal intent, aged 66.

Joseph Alfred Beall, M.D. Hospital College of Medicine, Louisville, 1891; a member of the State Medical Association of Texas; local railway surgeon at Center Point; died at the home of his father in San Marcos, Dec. 11, 1910, aged 50.

Thomas Hamilton Gray, M.D. University of Michigan, Ann Arbor, 1871; a veteran of the Civil War; formerly a member of the Erie County (Pa.) Medical Society; died suddenly at his home in Erie, April 5, from rheumatism, aged 70.

William Covington Wall, M.D. Pennsylvania Medical College, Gettysburg, 186—; formerly a member of the DeSoto County (Miss.) Medical Society; died at his home in Hernando, July 2, 1910, from uremia, aged 73.

Hiram Harrison Miller, M. D. Medical College of Virginia, Richmond, 1861; a member of the Medical Society of Virginia, and a Confederate veteran; died at his home in Elkton, April 10, from cerebral hemorrhage, aged 73.

Charles A. O'Brien, M.D. St. Louis College of Physicians and Surgeons, 1897; of Fillmore, Ind.; formerly coroner of Putnam County; was found dead in Fillmore, April 7, from the effects of an overdose of chloral.

James Lewis Miller, M.D. Eclectic Medical Institute, Cincinnati, 1894; formerly of Providence, R. I.; a specialist on diseases of the eye, ear and throat; died at his home in Pendleton, Ore., Sept. 27, 1910.

George Gleason Sabin, M.D. University of Michigan, Ann Arbor, 1868; for thirty years a practitioner of Black River, N. Y.; a veteran of the Civil War; died at his home, March 28, from paralysis, aged 72.

Oliver Perry Piper, M.D. Jefferson Medical College, 1872; for fifteen years a practitioner of Schuylkill Haven, Pa.; and physician to the Schuylkill County Hospital; died in Harrisburg, March 17, aged 62.

Edward A. Flewellen, M.D. Jefferson Medical College, 1851; inspector of hospitals in the Confederate service during the Civil War; died at his home, The Rock, Ga., Dec. 9, 1910, from pneumonia, aged 93.

Telemachus N. Bennett, M.D. Kentucky School of Medicine, Louisville, 1893; for two terms deputy coroner of Marion County, Ind.; died at his home in Broad Ripple, April 12, from nephritis, aged 68.

Maria J. Cushing, M.D. New York Medical College and Hospital for Women; for many years a practitioner of Washington and New York City; died at her home in Lynn, Mass., April 9, aged 76.

Lucius A. Squires, M.D. Castleton (Vt.) Medical College, 1851; one of the oldest practitioners of Columbus County, Wis.; died at his home in Poynette, April 10, from paralysis, aged 86.

Edgar T. Walker, M.D. Tulane University, New Orleans, 1882; of Trinity, Tex.; local surgeon for the Missouri, Kansas and Texas Railway; died in San Angelo, Tex., March 31, aged 61.

William Munro Workman, M.D. Hahnemann Medical College, Chicago, 1883; a veteran of the Civil War; died at his home in Grand Junction, Ia., March 15, from heart disease, aged 68.

Rose DeL. Winters, M.D. Homeopathic Medical College of Missouri, St. Louis, 1900; of Kansas City, Mo.; died in Mercy Hospital, Clinton, Ia., February 16, from typhoid fever, aged 49.

Hugh L. Kimberlin, M.D. Kentucky School of Medicine, Louisville, 1852; a retired practitioner of Mitchell, Ind.; died at his home, Dec. 2, 1910, from chronic nephritis, aged 79.

Nathaniel P. Jelks, M.D. Bellevue Hospital Medical College, 1868; a member of the Medical Association of Georgia; died at his home in Hawkinsville, March 27, aged 65.

Howard Miller Taggart, M.D. University of Pennsylvania, Philadelphia, 1896; of Wilkes-Barre; died at a cottage on Wilkes-Barre Mountain, March 30, aged 44.

John Allen White, M.D. Tulane University, New Orleans, 1853; a Confederate veteran; died at his home in Huntsville, Tex., April 3, from senile debility, aged 81.

William D. Bell, M.D. Jefferson Medical College, 1855; a member of the Louisiana State Medical Society; died at his home in Lake Providence, April 9, aged 82.

John Perrie, M.D. Washington University, St. Louis, 1867; a Confederate veteran; of Mayview, Mo.; died in Eads, Colo., March 23, from peritonitis, aged 70.

Edmond James McLennan, M.D. Trinity Medical College, Toronto, 1890; died at his home in Medford, Okla., January 27, from heart disease, aged 46.

Alfred D. McMaster, M.D. Missouri Medical College, St. Louis, 1879; died at his home in Le Grand, Cal., January 26, from nephritis, aged 54.

Daniel Webster Camp, a practitioner of Wyalusing, Pa.; died at his home in that place, February 6, from valvular heart disease, aged 65.

Joseph W. Taylor, M.D. Memphis (Tenn.) Hospital Medical College, 1894; died at his home in Hickory Valley, Tenn., April 3, aged 38.

Joseph Fred Demers, M.D. Laval University, Quebec, 1894; died at his home in Levis, Que., Dec. 26, 1910, from typhoid fever, aged 39.

George Taylor, M.D. University of Louisville, Ky., 1910; died at his home in Kempton, Ill., April 1, from appendicitis, aged 23.

Elston Chamberlain, M.D. Rush Medical College, 1863; died at his home in Dallas, Tex., February 22, from pneumonia, aged 69.

Frank G. Osborne, M.D. University of Buffalo, N. Y., 1868; died suddenly at his home in East Aurora, N. Y., March 2, aged 66.

Allen V. Wright (years of practice, Tex.); died at his home in Corsicana, June 31, 1910, from nervous prostration, aged 71.

Diagnosis of Tuberculosis of the Breast.—This may give rise to much difficulty. The infection may remain localized to one portion of the breast, and give rise to a hard, painless mass. Eventually, softening occurs with the formation of subcutaneous abscess, and sinus formation of this may be delayed for some time.—H. M. Rigby, in the *Practitioner*.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession.

PANTOPON REJECTED

Report of the Council on Pharmacy and Chemistry

A referee of the Council reported that Pantopon was not eligible for inclusion with New and Nonofficial Remedies and recommended that the reasons for its rejection be published. The Council voted to adopt this recommendation and in accordance with its regular procedure the facts were reported to the manufacturers before publication. The firm's reply having been received, the Council authorized publication of the report which appears below.

W. A. Puckner, Secretary.

PANTOPON

Under this name, the Hoffmann-LaRoche Chemical Works submitted a pharmaceutical preparation of opium, consisting of a mixture of the hydrochlorids of the various opium alkaloids, as extracted directly from the drug, with more or less purification.

The Council holds that this name does not effectively suggest that the preparation is a mixture of opium alkaloids, as is required by the part of Rule 8 which reads:

> "In the case of pharmaceutical preparations or mixtures the trade-name must be so framed as to indicate the most potent ingredients."

and further explains:

> "It is particularly important that actively poisonous or habit-forming drugs be not disguised under an innocently worded title."

The Council maintains that the name "Pantopon" does not sufficiently protect the public against the habit-forming and other dangers inherent in such mixtures. The manufacturers, on being informed of these objections, offered to substitute the name "Omopon." As this is open to the same objections, it could not be accepted by the Council. After much correspondence, the manufacturers refused to consider any other name which would more definitely suggest its composition.

The Council is therefore forced to reject the product and has ordered the publication of this report.

Comment: This is a case in which the rules of the Council are in conflict with the views of the manufacturers and the Council is bound in consistency to stand by its rules, which are framed to protect the public and the profession. Pantopon is not a definite chemical body; but a mixture of known substances—the several alkaloids naturally occurring in opium—and the Council's rules require that such a preparation should bear a name indicative of its composition. The name "Pantopon" although it might suggest opium to those well acquainted with Greek would not do so to all and it would be relatively easy for physicians to fall into the habit of using it indiscriminately without realizing fully the character of the preparation, and the preparation thus becomes a menace to the public.

As to the merits of the preparation itself, it is remarkable what a literature has been built about a simple mixture of the opium alkaloids. The preparation is claimed to be superior to opium because it is more readily soluble. This trifling advantage seems to have been sufficient, however, to justify the publication of a dozen or more pamphlets. But in reality, this preparation is nothing more, therapeutically, *than a form of* opium and, therefore, should be known to the physician as opium. The reports made of its action seem to indicate a lack of critical sifting of the evidence. Notwithstanding *both its* source and the fact that experimental and clinical reports emphasize its close resemblance to opium and morphin, one author (H. Haymann, "Pantopon in der Psychiatrie," *Münch. med. Wchnschr.*, No. 43, 1910) remarks that a habit was not produced, inferring that something in the character of the preparation prevented the formation of such a habit.

The one thing to be kept in mind in considering the claims made in the literature for this preparation is that it represents opium and opium only and any statements of its superiority to opium must be read in the light of the well-known tendency of writers to exaggerate the virtues of proprietary substitutes for official substances.

PAPINE

A Disguised Morphin Solution

To the thinking physician it should be evident that a preparation containing morphin must possess not only all of the valuable properties of this drug, but also all of the objectionable ones. There are still some physicians, apparently, who give credence to the assertions of the manufacturers concerning a morphin preparation from which, it is claimed, all of the undesirable morphin effects have been removed. The following query from a correspondent illustrates this fact:

> "Will you inform me as to the contents of "Papine"? I have a case of chronic interstitial nephritis, and my consultant insists on giving this preparation. I asked him if he knew what drugs it contained and his answer was 'one-eighth of a grain of morphin with the objectionable parts of the drug removed.'"

The query was referred to the Association Laboratory, which submitted the following report:

For many years Papine has been advertised by its makers, Battle & Company, St. Louis, as an anodyne. In the circulars Papine is described in part as follows:

> "Papine represents in pharmaceutical form the purely anodyne principles of opium freed from the narcotic and tetanising constituents."
>
> "Papine is the anodyne or pain-relieving principle of opium; the narcotic and convulsive elements being eliminated. One fluid drachm is equal in anodyne power to one-eighth grain of morphin."
>
> "Through special methods of preparation, the anodyne and analgesic principles of *Papaver somniferum* are so extracted as to free them of the narcotic and convulsive elements that ever have been, and must ever continue to be serious objections to the use of opium and its common derivatives. . . . No demand is more regularly made on the physician than that for the relief of pain, and to be able to afford it promptly and completely, without the slightest deleterious action, is an advantage that cannot be overestimated."
>
> "Unlike most derivatives and preparations of opium, Papine neither nauseates nor constipates; nor does it inhibit the secretory functions of the body."
>
> "In conditions of extreme nervousness, especially in women, recourse to morphin is attended by the very real danger of the formation of a habit. Lastly, opium and its alkaloids must not be administered to persons whose kidneys are not in good working order on account of the risk of toxic accumulation."
>
> "No such restriction exists in respect of Papine, its action being exerted exclusively on the element pain; in other words, it is purely anodyne."
>
> "Papine does not nauseate, constipate nor create a habit."

From these statements the incautious physician might be led to infer that Papine is a preparation analogous or similar to the official tincture of deodorized opium. Formerly in the manufacture of the latter preparation, in addition to removal of the odorous substances, narcotin, then thought to be the principal convulsive alkaloid,[1] was also removed. By the process for the manufacture of this tincture, which is now official in the United States Pharmacopeia, most of the narcotine is found in the finished preparation. While it is a comparatively simple matter to remove the narcotin from opium and its preparations, thus eliminating most of the commonly reputed "convulsive elements,"[2] to remove the "narcotic elements" from opium would result in destroying the integrity of the product. The reasons for this are that morphin is the most powerfully narcotic substance found in opium, and it is present in the largest proportion of any of the alkaloidal constituents. Its removal from an opium preparation would, therefore, render that preparation practically valueless.

---

[1] Narcotin is now known to possess very little physiologic effect.

[2] Of the opium alkaloids, laudanin and thebain possess the most powerfully tetanizing properties, but they are present in opium in too small quantities to produce any noticeable effect. Neither of these alkaloids is removed by the usual processes for "denarcotizing" opium.

From Papine, however, the morphin has not been removed, for *since the passage of the Food and Drugs Act* the label has to admit that Papine contains 1 grain of morphin in each ounce!

A specimen of Papine was examined[3] and found to be nothing more than a simple aqueous-alcoholic solution of morphin, containing glycerin. The preparation is flavored to imitate cherry and colored with cochineal. With the exception of morphin, neither narcotin, codein nor other opianic alkaloids were found, while meconic acid, a characteristic constituent of opium, was absent. Since Papine is claimed not to cause constipation, and as is well known, this condition is frequently produced by morphin, it seemed possible that Papine might contain laxative substances. On examination, however, neither cascara, rhubarb, phenolphthalein nor laxative salts were found.

While Battle & Co. have persistently exploited Papine as being an opium preparation having none of the objectionable qualities of opium, the analysis shows that the paradoxical claims made for it cannot be substantiated. In prescribing morphin there is an abundance of official preparations to choose from, and there certainly is no necessity or excuse for resorting to the much more expensive and in no way superior Papine.

Miscellany

Increase of Pay for Officers of the Public Health Service

Senator Owen has introduced the following bill, which appears on the Senate Calendar as S. 1182. It has been referred to the Committee on Public Health and National Quarantine:

A bill to promote the efficiency of the Public Health and Marine-Hospital Service.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the salary of the surgeon-general of the Public Health and Marine-Hospital Service shall be $6,000 per annum, and the salary of the assistant surgeon-general shall be $500 in addition to the pay and allowances of his grade; for the ten senior surgeons on the active list, $3.500; for surgeons, $3,000; for passed assistant surgeons, $2,400; for assistant surgeons, $2,000; and the longevity pay and allowances of the said commissioned medical officers shall be the same as now provided by law: *Provided*, That the retirement of the commissioned medical officers shall be the same as is now provided for medical officers of the Navy.

Another personnel bill has been introduced into the House of Representatives by Mr. Edwards. It appears on the House calendar as H. R. 5599, and is as follows:

A bill to promote the efficiency of the Public Health and Marine-Hospital Service.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That hereafter the salaries of the commissioned medical officers of the Public Health and Marine-Hospital Service of the United States shall be at the following rates per annum: surgeon-general, $6.000; assistant surgeon-general, $4,000; senior surgeon, in which grade there shall be ten in number on active duty, $3,500; surgeon, $3,000; passed assistant surgeon, $2,500; assistant surgeon $2,000; and the said officers, excepting the surgeon-general, shall receive an additional compensation of 10 per cent. of the annual salary as above set forth for each five years' service, but not to exceed in all 40 per cent.: *Provided*, That the total salary, including longevity increase, shall not exceed the following rates: assistant surgeon-general, $5,000; senior surgeon, $4,500; surgeon, $4,000.

When officers on active duty are not provided quarters, fuel and lights, they shall receive the same commutation therefor as now allowed medical officers of similar grades in the Navy: *Provided*, That officers while serving outside the boundaries of the continental United States shall receive an additional 10 per cent. of their salaries and increase while on such duty.

The allowance for baggage and personal effects to an officer in changing stations shall be fixed by the Secretary of the Treasury, not to exceed in any case 7,200 pounds.

Vacancies in the grade of senior surgeon shall be filled by promotion, after satisfactory examination, from the grade of surgeon and in the order of seniority of said grade; passed assistant surgeons shall be promoted to the grade of surgeon in the order of seniority at the expiration of twelve years' commissioned service and after satisfactory examination; assistant surgeons shall be promoted to the grade of passed assistant surgeon in order of seniority at the expiration of three years' commissioned service and after satisfactory examination.

Treatment of Gonorrhea.—N. E. Aronstam discusses the treatment of this disease as follows: The abortive plan of treatment is both painful and inefficient. To determine its value the microscope must be always consulted. There is no specific treatment for gonococcic urethritis and some of the much-lauded remedies are worthless, to say the least. Mechanical means, such as injections and irrigations, are apt to injure the urethral mucosa and cause extension of the gonorrheal process. The modern silver preparations, although efficacious and prompt in a number of cases in checking the purulent discharge, are not entirely devoid of danger, as complications are prone to develop in the course of such treatment. Rest is of paramount importance in the treatment of gonorrhea. Gonorrhea must always be regarded as a grave and far-reaching affection. The expectant plan of treatment, although not so prompt as the more rigid aggressive methods, is, however, devoid of all danger and the possibility of complications.—*Detroit Medical Journal.*

---

[3] DETAILS OF ANALYSIS: Papine is a dark purplish liquid having a cherry-like odor and a sweetish taste. The specimen examined had a specific gravity at $\frac{25° C.}{25° C.}$ of 1.0565.

Qualitative tests indicated the presence of morphin, ethyl alcohol, glycerin and cochineal. Small amounts of a chlorid and traces of a sulphate were present. Acetates, lactates and sugars were absent.

Opium Constituents.—From the claims made for the preparation by the manufacturer, it might possibly be inferred that Papine is similar to the official tincture of deodorized opium. Accordingly, tests were made for opianic alkaloids other than morphin and for meconic acid. A portion of the specimen was dealcoholized, diluted with water and shaken with ether. The solvent was washed with water and portions evaporated. The residue from one portion of the solvent was very small; it was taken up in a small quantity of diluted hydrochloric acid and the solution filtered. On the addition of bromin to this solution, no precipitation took place, and on subsequent boiling the solution did not become rose-red. This was taken to indicate the absence of narcotin in Papine. The portion of dealcoholized Papine which had been shaken with ether was made alkaline with ammonia water and the mixture shaken with ether. The solvent was washed with water and shaken with diluted hydrochloric acid. The acid solution was made alkaline with ammonia, shaken with chloroform and the solvent evaporated. Only a very slight residue remained. This was subjected to the usual tests for codein, but with negative results.

A portion of the dealcoholized Papine was slightly acidified with hydrochloric acid and shaken with ether. The washed solvent was evaporated, the residue taken up with water and the solution treated with a drop of diluted ferric chlorid test solution. A red color was not produced. A portion of dealcoholized Papine was treated with a slight excess of lead acetate test solution, the precipitate washed with water, suspended in water and hydrogen sulphid passed in. The precipitated lead sulphid was removed by infiltration, the filtrate evaporated to a small bulk and treated with ferric chlorid test solution. No red color was produced. These tests indicated the absence of meconic acid. No odor similar to opium was observed at any stage of the examination.

As a check an aqueous extract of opium was prepared and subjected to the tests above described. A positive result was obtained in each case.

Laxative Substances.—A portion of the dealcoholized Papine was acidified with hydrochloric acid and shaken with ether. The washed solvent gave no red coloration on addition of ammonia water (absence of emodin and phenolphthalein). A small portion of the material was ignited. Only a trace of ash was given (absence of Epsom salts, Glauber's salt, etc.) These tests were taken to indicate the absence of the more common laxative substances.

Cochineal.—A portion of the dealcoholized specimen was slightly acidified with acetic acid shaken with amyl-alcohol, the solvent washed with water and shaken with a 1 per cent. solution of uranium nitrate. A deep green color was produced at once.

Chlorid.—Chlorid was determined as follows: Fifty c.c. were dealcoholized, diluted with 200 c.c. water, 10 c.c. nitric acid added, chlorid precipitated with silver nitrate, the precipitate collected, washed, dried, heated and weighed in the usual way. The results were calculated to crystallized morphin hydrochlorid ($C_{17}H_{19}NO_3.HCl + 3H_2O$) and to the equivalent of this salt in crystallized morphin ($C_{17}H_{19}NO_3 + H_2O$). From 50 c.c. of the solution 0.487 gm. silver chlorid was obtained; from a duplicate of 50 c.c. of the solution 0.481 gm. silver chlorid was obtained; average, 0.484 gm. silver chlorid. This is equivalent to 0.0968 gm. silver chlorid from each 100 c.c. of solution, or the equivalent of 0.2536 gm. crystallized morphin hydrochlorid in each 100 c.c. This quantity is equivalent to about 1.15 grain morphin hydrochlorid in each fluid ounce, or about 0.93 grain of crystallized morphin in each fluid ounce.

Since the label states that Papine contains 1 *grain of morphin* in each ounce, the findings from the chlorin determinations were taken to indicate that the morphin is present in the preparation combined as hydrochlorid.

Correspondence

Prevention of Pulmonary Tuberculosis

To the Editor:—In THE JOURNAL, April 22, 1911, page 1195, among "points which must not be forgotten," I should have been much gratified if you had mentioned the great importance of wearing a perforated zinc inhaler with suitable inhaling fluids, the best of these being equal parts of creosote, alcohol and spirits of chloroform. By the continuous and proper use of this fluid much can be effected in the way of prevention of the disease, not to speak of its very great value as a curative measure. To-day it is sad to note how little is done beyond mere sanitary regulations and hygienic régime to arrest the disease and cure an immense number of sufferers from tuberculosis; and practically nothing else is done to shield an equally large number of people *from contracting the disease.* For many years I have advocated strongly and frequently the value and importance of continuous antiseptic inhalations in pulmonary tuberculosis as a curative measure. I am equally impressed with its urgency as a protective measure, and especially with a vast majority who cannot go to sanatoriums or get the comforts and surroundings which wealth alone gives.

BEVERLEY ROBINSON, New York.

Hexamethylenamin in Pellagra

To the Editor:—In THE JOURNAL, Nov. 5, 1910, p. 1663, I reported a case of pellagra in which I treated the patient with hexamethylenamin. I stated results of the treatment, which were remarkable, although I had given the patient this treatment only a short time. The patient has continued to improve until she now feels perfectly well. By Christmas she had gained 40 pounds in weight, which she has held until the present time. When I began to treat her, I gave 45 grs. of hexamethylenamin every day for three weeks; then 30 grs. a day for one month. On account of the irritating effects on the bladder, I had to discontinue the drug only a few days during his time. During the winter and spring she has been taking 0 grs. a day for three days and missing three days. This is the only treatment she has taken since she has been under my care.

While one case proves nothing, yet the result in this case is so much better than any I have ever read of that I feel that I should report it. I hope that others, who have a number of cases, may try it.

B. B. BAGBY, M.D., West Point, Va.

Overcrowding in the Medical Profession in the West

To the Editor:—It might not be out of place to utter a caution to medical men contemplating settlement in the West. On account of the heavy expense incident thereto, any physician contemplating removal to the West should, if possible, make a trip first and look into matters closely before deciding.

The entire western country is very much congested with physicians of all kinds, and many of them, after spending a year or two in any of the western cities, will find their savings gone in the high cost of living and extortionate rents.

It must be remembered that many medical students in the West are constantly preparing to enter the profession in sufficient numbers to meet the demands of the increasing population.

DAVID H. LEWIS, Salt Lake City.

The Round-Ligament Operation

To the Editor:—In a recent issue of THE JOURNAL (Feb. 18, 1911, p. 481) is an article by Dr. J. M. Baldy entitled "Operation for Retrodisplacement of the Uterus." I desire to point out that the procedure described is exactly that which was first published by me in THE JOURNAL (Oct. 5, 1901).

I am highly gratified that Dr. Baldy advocates the operation so strongly in his paper; but, though he refers to "Webster, who has for the same length of time performed an operation with exactly the same principles"—his description is of such a character as to be very liable to give readers the impression that the operation is Dr. Baldy's invention.

This is not the first paper by him in which there is danger of similar misunderstanding. In the *New York Medical Journal* (April 14, 1906, p. 741), the same operation was described without the slightest reference to my share in originating it. I now consider that it is time to point out what Dr. Baldy has really done and to correct some misrepresentations.

In his recent paper the following sentences occur: "The operation is not new. I first referred to it in a paper in 1902." These statements are incorrect.

The operation was originally described by me in THE JOURNAL, Oct. 5, 1901, its essential features consisting in perforation of the broad ligaments, seizing the round ligaments with forceps and drawing them double under the utero-ovarian ligaments, and stitching them to the back of the uterus.

In Dr. Baldy's first paper (*Am. Jour. Obst.*, May, 1902, p. 650), seven months later, he commends the principle of my operation, criticizes my method of doubling back the round ligaments and there describes his own procedure, which he regards as an improvement, viz., *dividing the round ligaments close to the uterus and drawing them through the broad ligaments attaching them to the posterior surface of the uterus.*

Here, then, in clear language is Dr. Baldy's first published account.

I may say, in passing, that I carried out this procedure in a few cases several years ago, but abandoned it as unnecessary. Moreover, there is more liability to intestinal adhesions in connection with it, as some raw edges are apt to be left exposed.

Four years later Dr. Baldy published an article in the *New York Medical Journal* (April 14, 1906, p. 741) of a somewhat amazing character. I quote his own account:

"The *operation* which I am in the *habit of performing for* backward displacements of the uterus, and which is frequently designated *by my name*, is one which obtains its result *through* the use of the round ligaments. The broad ligaments are perforated from their posterior surface by forceps which, on emerging on the anterior surface, are made to grasp the round ligaments, which are then drawn through to the posterior surface with the forceps. The round ligaments are brought together and sutured both together and to the uterus. One who has not seen the result (of this operation) can have no conception of its completeness." Here is evidence of a complete change in the author's practice.

The operation which he lauds so highly is the very one which was described by me in 1901 and which was discarded by him in 1902. He has described my procedure as his own and has not even mentioned my name in the entire paper.

Again in 1909 (*Ann. Gynec. and Pediat.*, May, 1909, pp. 142-146) he describes the operation without any reference to me.

It is not pleasant to me to carry a grievance into print but I cannot remain silent while another claims credit which is not his due. My operation has been described as Dr. Baldy's in a foreign work by Hartmann of Paris, and I consider it time to interfere lest further misrepresentations should appear in medical literature. Moreover, I desire to make it clear that Dr. Baldy, having acknowledged the importance of the principle introduced by me in the surgical treatment of retrodisplacements, criticized my method of operation and recommended another procedure of obtaining the same result. He then abandoned the latter and after four years redescribed my original operation, praising it highly but giving me no credit for it. This line has been followed by Dr. Baldy in other papers to which I have referred, until the impression has been created in various quarters that he is the originator of the procedure.

J. CLARENCE WEBSTER, M.D., Chicago.

[This letter was referred to Dr. Baldy, who replies as follows:]

To the Editor:—A careful reading of Dr. Webster's letter will fail to elicit any false statement which he attributes to me. He makes a statement which is directly contrary to fact when he says that I have ever claimed priority, directly or indirectly. He quotes from two of my papers in which I give him full credit but, with apparent intention, he omits to say so, and he quotes an unimportant paper in which his name does not appear as proof of his claim that I pretend to priority. Dr. Webster seems to feel that the operation I described in 1902 is not the same as the one I am now doing. The operation which I described in 1902 consisted in "dividing the round ligaments close to the uterus, and drawing them through the broad ligaments attaching them to the posterior surface of the uterus." What I do now is to draw the round ligaments through the broad ligaments without cutting them, attaching them to each other, and, incidentally only, to the posterior surface of the uterus. Dr. Webster, so far as I can learn from those who have seen him operate, draws the round ligaments through the broad ligaments without cutting them, and attaches them to the posterior surface of the uterus. The principle of these three procedures is the same, and as Dr. Webster gives me credit for the first one, then I claim absolute credit for the second one, the one I am now doing and have done for some years. I have never seen it described by him nor has anyone who has seen him do the operation told me that he does it as I do it. The third method only is his; I claim the other two.

He brings the round ligaments through the broad ligaments, spreads them out over the posterior cornu of the uterus, and stitches them to the uterus, making the full support depend on the suture in the uterus. He does not bring the ends of the ligaments together posteriorly and stitch them together, as I do. Bringing the ends of the ligaments together and stitching them by my present method, makes the whole integrity of the operation depend on the juncture of the ligaments, and the stitch holding the ligament to the uterus is a mere incident, and could be left out.

The method he follows to-day is exactly like my original method, less the fact that I severed the round ligaments and he does not. The method I follow to-day is in no respect like his, except that I no longer sever the round ligaments, but bring them through double, as he does. In other words, his present method is as much like my original one as my present method is like his. If I have appropriated from him for this, so also has he appropriated from me. The truth is that he has modified his details, and I have modified mine. He has adopted as much of mine, as I have of his.

I reiterate most emphatically there is not an iota of difference in principle between what he has been doing for years and what I have been doing for the same length of time, the details of technic are unimportant in the issue, and I have as much right to them as he has, whether he has used them or not.

This brings me to the question of my right to have a hand in the development of this achievement. His first article appeared Oct. 5, 1901. My first paper was read before the Section of Gynecology, College of Physicians of Philadelphia, Feb. 20, 1902. This is an interval of more nearly four months than seven (apparently another deliberate misstatement of his); therefore our original papers were essentially produced at one and the same time, and it can hardly be doubted but that we had, both of us, been working at the subject for a long time beforehand, a thing which has occurred often with different men in different parts of the world.

As for my having withheld credit from him for his work, this is a misrepresentation which certainly seems to be a deliberate one. During all these years I have written exactly three papers of importance dealing directly with this operation. In each of these, I have given full credit to Dr. Webster.

In my original paper, in the *American Journal of Obstetrics and Diseases of Women and Children*, xlv, No. 5, 1902, I discuss in full, using his name, the merits and demerits of both procedures. I go even further in this: I held my paper up for a month after writing it in order to write Dr. Webster, and I added the final paragraph of the paper, giving him additional credit for the contents of his letter. If I take credit for that month, there was in reality only three months between the publications of our work.

My second important publication is found in *Surgery, Gynecology and Obstetrics*, Chicago, April, 1909, pp. 421-434. In this paper I state: "The mechanism is plain, but has never to my knowledge, been fully appreciated or fully pointed out even by Webster, who has, for the same length of time, performed an operation with exactly the same principles, but varying slightly in technic."

In my third important publication on this operation, in THE JOURNAL of the American Medical Association, Feb. 18, 1911, I repeat this statement.

In addition to all this, for years it has been my invariable custom in my lectures at the Philadelphia Polyclinic always to mention the name of Dr. J. Clarence Webster in connection with the operation and to give him full credit. Hundreds of men can readily bear witness to this fact. What has been his treatment of me in all these years? He has never once mentioned my name in connection with this procedure except to abuse me.

The sum total of his charge is that the operation I did originally is entirely different from the one he did. This I deny emphatically. The principle of each is precisely the same. He charges that I claim, and have claimed, priority to this principle, directly or indirectly. I have clearly shown that I do not, and never have claimed priority, but have always given him equal and due credit.

I, however, have, and do claim, that I evolved the principles of the operation at or about the same time as Dr. Webster, and I claim the right to go ahead, and develop that principle in all its details, irrespective of what rights he thinks he has in the premises.

J. M. BALDY, Philadelphia.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

CAUSE OF CONVULSIONS IN INFANTS

To the Editor:—At a recent meeting of our county society the cause of convulsions in a breast-fed infant of six months was discussed. As etiologic factors the following were mentioned: gastro-intestinal disturbances, adherent clitoris or prepuce, worms, especially roundworms, etc. The question as to what were the common causes of convulsions in infants was discussed, especially the possibility of round-worms being an etiologic factor. What are the possibilities of *Ascaris lumbricoides* causing convulsions in infants, and how frequently are they found in breast-fed infants?

A. Z., Iola, Kan.

ANSWER:—Convulsions in infancy are of three kinds: (1) those due to organic changes in the brain, meninges or skull; (2) those due to epilepsy; (3) those due to tetany. Practically all the so-called reflex convulsions—the convulsions at the onset of acute infections, during the course of gastro-intestinal disturbances—are dependent essentially on a chronic hypersensitive condition of the central nervous system as manifested by electrical and mechanical reactions, and with a tendency toward convulsions, laryngismus stridulus and carpopedal spasms. The two commonest names for this group are spasmophilic diathesis and tetany. The tendency to convulsions is manifest before the actual convulsions occur (latent tetany), and by electric examination one can foretell in a large percentage of cases which infants will tend to have convulsions at the onset of an acute illness.

The cardinal symptoms of tetany are: 1. Erb's phenomenon: This is the response of the motor nerves to minute galvanic currents. Pathognomonic for tetany and most important especially in the latent cases, because it may be the only sign present, is the cathodal opening contraction with a current of less than 5 milliamperes. 2. Chvostek's sign: By tapping the facial nerve a contraction occurs in the muscles of the face supplied by that nerve. 3. In the more severe cases tapping the muscles will produce a contraction; this is best seen by tapping the extensors of the leg. 4. Trousseau's sign: By constriction of the upper left arm the hand will take on the obstetric position; the hand will be flexed at the wrist and the forearm flexed at the elbow.

Thus by electric examination one can determine whether a case belongs in Group 3 or in Group 1 or 2. Almost constantly associated with tetany are more or less marked evidences of rachitis, and it is supposed that both depend on a common error in the metabolism, especially of the calcium salts.

The question of roundworms causing convulsions during the first six months of life of a breast-fed infant is one that can be answered in the negative. Practically all breast-fed children are guarded against the possibility of infection with roundworms; that is, taking the worm larvæ in their food, or by playing on the ground getting the larvæ in their fingers and carrying them thence to their mouth. Recent experiments have shown that from the roundworm toxins can be obtained that act markedly in the gastro-intestinal tract and nervous system. The belief that convulsions occur as the result solely of worms is becoming rarer as the true causes of convulsions are becoming known.

JELLYFISH STINGS

To the Editor:—I have read with much interest your notes on jellyfish sting and am struck by the fact that, although apparently *Physalia* is sometimes a very active poisoning agent, as it is found in our latitude it seems to have lost most of its virulence. On three or four occasions in the last twenty years I have captured a *Physalia* off Newport, R. I., and, though always stung quite unpleasantly, I never found it necessary to resort to any treatment; nor did my father, who has an exceptionally tender skin.

Malcolm Storer, M.D., Boston.

To the Editor:—In connection with the article on sting of Portuguese man-of-war published in The Journal, April 22, I would refer you to the adventure of the celebrated Captain John Smith of Virginia with a sting-ray as given in Smith's own history of Virginia.

Jesse Ewell, M.D., Ruckersville, Va.

SLANDERING THE FLEA

To the Editor:—It is a curious coincidence that the leading German weekly, the *Deutsche med. Wochenschrift,* makes the same mistake that The Journal did (April 8, page 1073) in its abstract of Nicolle's work on typhus. [Corrected April 22, page 1236.]

The German *Wochenschrift* states in its abstract of Nicolle's work, April 6, page 657, that *Flöhe,* "fleas," are involved in the transmission of the disease. What can there be in Nicolle's article that hypnotizes reviewers into mistaking lice for fleas? It is to be hoped that the Flea family will not take revenge on the reviewers for this baseless calumny! At the same time, as the darkey said afterward when his minister had accused him of having stolen some chickens and he was able indignantly to deny the accusation, "If he had said ducks he would have got me."

S.

FILTER WANTED FOR CISTERN

To the Editor:—Please tell me how to construct or where to buy a cheap but effective filter for water running off a roof into a cistern. The water will be used for drinking purposes.

Paul D. Espey, Port William, Ohio.

The Public Service

Medical Department, U. S. Army

Changes for the week ended April 22, 1911.

Williamson, L. P., lieut., left Hachita, N. M., with Co. I, Signal Corps, en route to San Antonio, Texas.

Gosman, George H. R., major, orders directing him to proceed to the Philippine Islands for duty revoked.

Bernheim, J. R., D.S., left San Francisco on two months' leave of absence.

Ingalls, R. E., D. S., ordered to proceed from Fort Douglas, Utah, to Fort Huachuca, Ariz., for temporary duty.

Hewitt, John M., M.R.C., relieved from duty at U. S. military prison, Fort Leavenworth, Kan., and assigned to duty on the transport *Dix*, relieving First Lieutenant James B. Ferguson, Medical Reserve Corps.

Griffis, Frank C., M.R.C., relieved from duty at Fort D. A. Russell, Wyo., and ordered to Henry Barracks, Porto Rico, for duty, relieving First Lieutenant Thomas M. Foley, Medical Reserve Corps, who will proceed to New York City for further orders.

Porter, Ralph S., captain, relieved from duty at Army General Hospital, Fort Bayard, N. M., and ordered to Fort William H. Seward, Ala., for duty, relieving Captain Fred W. Palmer, Medical Corps, who will proceed to Seattle, Wash., for further orders.

McAlister, John A., Jr., D.S., will proceed to San Antonio, Texas, for duty with maneuver division.

Cutliffe, William O., M.R.C., relieved from treatment at Walter Reed General Hospital, Takoma Park, D. C., and will return to his station.

Hill, Eben C., lieut., ordered to Walter Reed General Hospital, Takoma Park, D C., for observation and treatment.

McAlister, John A., Jr., granted leave of absence for ten days.

Brownlee, C. Y., major, left Fort Des Moines, Iowa, with the 1st Squadron, 6th Cavalry, en route to Douglas, Ariz., for duty.

Wing, F. F., D.S., returned to Fort D. A. Russell, Wyo., for temporary duty.

Worthington, J. A., lieut., reports assignment to temporary duty at Fort Riley, Kan.

Austin, Thomas C., lieut., ordered to sail for duty in the Philippine Islands, about August 5, instead of June 5, 1911.

Medical Corps, U. S. Navy

Changes during the week ended April 22, 1911.

Robnett, A. H., P. A. surgeon, detached from the marine corps rifle range, Winthrop, Md., and ordered to temporary duty at the naval hospital, Boston, and to duty on board the *New Jersey* when placed in commission.

Woods, E. L., P. A. surgeon, detached from the naval hospital, Annapolis, Md., and ordered to duty with the United States legation guard, Peking, China.

Owens, W. D., P. A. surgeon, detached from duty with the United States legation guard, Peking, China, and ordered home to await orders.

Boyd, J. C., medical director, transferred to the retired list from June 1, 1911.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended April 19, 1911.

Stimpson, W. G., surgeon, granted seven days' leave of absence from April 18, 1911, under paragraph 189, Service Regulations.

Nydegger, J. A., surgeon, granted one month's leave of absence from March 24, 1911, on account of sickness.

Wickes, H. W., surgeon, granted seven days' leave of absence from April 22, 1911.

Bryan, W. M., asst. surgeon, directed to report to the chairman of board of medical officers at Washington, D. C., April 24, 1911, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

Krulish, E., asst. surgeon, directed to report to the chairman of board of medical officers at Washington, D. C., April 24, 1911, for examination to determine his fitness for promotion to the grade of passed assistant surgeon.

Jones, O. E., A. A. surgeon, granted thirty days' leave of absence from April 20, 1911.

Walker, W. S., A. A. surgeon, granted seven days' leave of absence from April 13, 1911.

Medical Economics

This Department Embodies the Subjects of Post-graduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

PROGRESS IN STATE LEGISLATURES

ALABAMA

The governor has vetoed the optometry bill which passed the legislature under a misunderstanding of its provisions. The Justice bill, to amend the state medical practice act, is still before the legislature.

ARKANSAS

The state board of health bill has passed the senate.

COLORADO

The Sharpley bill (S. 63), to amend the medical practice act, has passed the senate. The Hasty bill, to require physicians to report all cases of tuberculosis and landlords to report all tuberculous tenants to the health officials, has passed the house.

ILLINOIS

H. B. 493, to provide for the registration of births and deaths, has been referred to the committee on sanitary affairs. This bill is modeled largely after the vital statistics bill drafted by the committee on medical legislation of the American Medical Association. The occupational disease bill passed the house by a vote of 105 to 1. This bill was drafted by a special commission appointed by the governor to investigate conditions in manufacturing establishments where poisonous materials were used, and is intended to protect employees in occupations that subject them to illnesses and diseases incidental to their work. The optometry and osteopathic bills in the senate and house are still in committee.

INDIANA

The McCarty bill, to provide for medical inspection of school children, has passed the house.

IOWA

The osteopathic bill has been killed in the committee on Judiciary. A bill introduced by Representative Miller, of Bremer County, to prohibit physicians and surgeons from entering into agreements regarding fees, was defeated in the house by a vote of 22 to 37. A bill to create a commission to investigate the causes of insanity, epilepsy, mental deficiency, delinquency and criminality has passed the house. A bill to provide for the sterilization of habitual criminals, imbeciles, idiots and feeble-minded persons confined in state institutions, has passed both houses.

MAINE

The osteopathic bill has been defeated by a small margin in the senate and by an overwhelming majority in the house. A bill designed to prevent physicians from carrying insurance against malpractice suits has also been defeated.

MICHIGAN

A chiropractic bill has failed to pass. A bill to amend the medical practice act has been withdrawn. A bill to require parties to a marriage contract to furnish a physician's certificate of good health before obtaining a license passed the house by a vote of 57 to 29. A bill which, according to the Bay City (Mich.) *Tribune*, is believed to emanate from the Antivivisection Society of New York, has been introduced; it provides that one-half hour every week be devoted in all the schools of the state to humane education. A bill to require local boards of health to report the effect of occupations on persons subject to tuberculosis has been signed by Governor Osborn. A bill to abolish the common drinking cups in all railroad cars except Pullmans, has passed the senate.

MINNESOTA

S. B. 787 to reduce the requirements for examination for physicians, has been withdrawn. A bill to require a license fee of $500 from Christian Scientists has been "definitely postponed."

MISSOURI

A bill authorizing the formation of districts for the prevention of tuberculosis has passed both houses of the legislature. It is understood that this bill has the personal endorsement of Governor Hadley. A commission appointed by the governor reports that there are between 6,000 and 7,000 cases of tuberculosis of the lungs in Missouri and that infection is transmitted through lack of proper care and precaution. The bill permits of the organization of districts throughout the state to avoid the further spread of the disease and to provide proper care and treatment for those already afflicted.

TENNESSEE

A vital statistics bill and a bill to amend the medical practice act have been introduced, also one providing for the medical inspection of school children. Another bill requires a health certificate as a condition for a marriage license. Through the efforts of the Tennessee Federation of Women's Clubs, a bill providing for the protection of the eyesight of new-born infants, has passed both houses of the legislature and has been signed by the governor. An amendment to the present excellent pure food and drug law, a sanitary hotel bill, an itinerant venders bill and a state hygienic laboratory bill have also been introduced.

NEW JERSEY

A bill to provide for the registration of trained nurses has been introduced, also a bill to amend the existing medical practice act.

NORTH CAROLINA

The legislature has adjourned after increasing the appropriation for public health from $8,000 to $22,000 and giving the state board of health an additional $5,000 to investigate the water-supply. A school for the feeble-minded has been established. A bill to permit the shipment of bodies from this state to other states for the purpose of anatomic work, has become a law. The legislature refused to appropriate $3,000 for free diphtheria antitoxin but appropriated $2,000 for the free treatment of hog cholera. A bill was passed allowing West Asheville to incorporate itself as a sanitary district and to vote a special tax by which to raise sufficient revenue for sanitary work, such work to be carried out by a commission under the direction of the county and state boards of health. It is hoped at the next session of the legislature to extend this privilege to all parts of the state so that any community county desiring may form a sanitary district to raise funds for public health work.

NORTH DAKOTA

H. B. 436 to require licenses of all hospitals and sanitariums and restricting major surgical operations, has been vetoed by the governor.

PENNSYLVANIA

A number of bills to amend the existing medical practice act have been introduced but none has as yet been passed. An antivivisection bill is in the house committee on public health and sanitation.

UTAH

Bills providing for reporting of contagious diseases by physicians and hotel and lodging-house keepers and reporting of inflammation of the eyes of new-born infants, have passed the house.

WISCONSIN

A bill to provide for medical inspection of school children is before the legislature and has been opposed by the Christian Science members of the National League of Medical Freedom.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—First Weekly Meeting

General Subject for the Month: Legal Medicine

Signs of Death

Somatic Death, Molecular Death

Cessation of Respiration: Auscultation, mirror to mouth, dish of water on chest, etc. Time.

Cessation of Circulation: Relation to respiration, tests. Eye changes. Changes in body temperature. Rigor mortis. Changes in skin.

Rigor Mortis and Putrefaction: Rigor mortis, onset, duration, causes. Effect of disease, violence, age.

Putrefaction: Onset, effect of moisture and temperature, bacteria, air, earth, and cause of death. Adipocere. Mode of decomposition of structures and viscera. Determination of time of death.

Causes of Sudden Death

Sudden Death Due to Natural Causes

Heart Disease: Cardiac thrombosis and embolism, myocarditis, rupture of heart, coronary disease, valvular lesions, aortic aneurysm.

Brain Lesions: Hemorrhages, embolism, thrombosis, in epilepsy.

Lesions of Respiratory Organs: Embolism, thrombosis, hemoptysis, pneumonia.

Hemorrhagic Pancreatitis.

Ectopic Pregnancy.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Fifth Annual Meeting, held at Albany, April 18-19, 1911

The President, Dr. Charles Stover, Amsterdam, in the Chair

PROCEEDINGS OF THE HOUSE OF DELEGATES

Dr. Charles Stover, Amsterdam: The Committee on Experimental Medicine is asking for the pecuniary support of this society in carrying on the work entrusted to it, and should receive it. The report of the Committee on Public Health is of more than ordinary interest in that it deals with the importance of establishing and maintaining county laboratories. The funds necessary for carrying to a conclusion the work that has been begun in relation to tuberculosis alone are so great that, inasmuch as the benefit to the public is correspondingly large, there is no reason why boards of health should not take on themselves the continuation of a great deal of the work that has been begun by private fortunes. This has already been done in some of the cities of the state where boards of health have taken over tuberculosis dispensaries originally started by branches of the state charities aid.

Report of the Committee on Experimental Medicine

The Committee on Experimental Medicine, in cooperation with the Committee on Legislation and with public-spirited men throughout the state, labored successfully to prevent the passage by the legislature of 1910 of two bills relating to experiments on living animals. One bill sought to impose restrictions, which were against the public welfare, on the performance of such experiments. A joint hearing before the judiciary committee of the senate and the assembly was held on Feb. 23, 1910. The other bill represented a new departure on the part of antivivisectionists in that it sought to establish a commission to inquire into the extent and nature of animal experimentation in this state. It was a real antivivisection measure thinly disguised. Hearings on this bill were held before the ways and means committee of the assembly and before the finance committee of the senate. The Committee on Experimental Medicine felt it to be its duty to combat the mistaken and unsound notions of their opponents relating to experimental medicine, and to oppose both bills, and its representatives appeared at the hearings and presented arguments to this effect before the legislative committees. Both bills died in committee. There is no doubt that again and again, with each succeeding year, this contest will be renewed; at least, so long as the funds provided for the purpose, and a willingness to regard experimental workers as unworthy of belief in the matter of their operative technic, continue. Every member of the profession should regard this controversy as a personal one, since the results affect all alike so far as the prevention and cure of disease are concerned.

Report of the Counsel

Mr. James Taylor Lewis, counsel for the society, reported on Medical Defense. Seventeen state societies have now adopted this feature, and the medical profession is fast coming to realize how important it is that its members should stand shoulder to shoulder in repelling vicious attacks on physicians, since there is no litigation more far-reaching in its importance, not only in its effect on the profession, but also by its indirect influence on the public health.

Report of the Committee on Public Health

While those colleagues who reside in large cities have every opportunity and facility in laboratory advantages, others in the smaller towns and villages do not, and the committee believes them to be entitled to every and any aid which can be given to them. These men stand in the front rank of earnest, honest, hard-working, self-sacrificing members of the medical profession, and they should not be denied these advantages simply because of their environment. Such laboratory facilities would not only enable county medical men to keep modern, but would exert a profound and lasting influence over the public at large. It is assumed that the thirty-eight counties in the state containing hospitals would be glad to furnish laboratory space for the *quid pro quo* of the paid resident pathologist and his assistant.

Report of Committee to Consider the Question of Increasing Interest in the Society

The fifty-eight county societies of the state represent at the present time a membership of about 7,000, and while there has been a steady growth each year, it is not large. If state, district branch, and county society meetings are improved, increased growth will necessarily follow. This committee offers the following suggestions for increasing interest in county societies:

1. Improve programs. Interest in the meeting depends largely on the attractiveness of the program.

2. Take up post-graduate course as recommended by American Medical Association. This systematizes the program.

3. Confer with state board of health for at least one meeting a year on public health matters. Cooperation with the health department is essential to the welfare of the community.

4. Have at least one speaker a year from a distance, obtained by conference with committee on scientific work of state society if necessary. It will be glad to suggest names of those willing to render such service.

5. Arrange for one or more clinical meetings a year. Select subjects and request all who have proper cases to bring them before the society. Then have a discussion, always with the understanding that discussion of the case shall not be held in the presence of the patient; otherwise, frequently patients cannot be shown for obvious reasons.

6. Arrange for demonstration by bacteriologists and pathologists, with specimens, lantern slides, etc.

7. Arrange for social part of meeting. Some light refreshments at the close of the meeting are an adjunct to fraternal intercourse.

8. See that meetings are held often enough to keep up interest. Once or twice a year is not enough. Invite every member of the profession in the county to at least one meeting a year, not necessarily inviting them all to the same meeting. In counties where men do not show a willingness to write papers either designate writers for different meetings or see that outsiders are invited. In other words, see that the meetings are made interesting. It should be the aim of every county society to secure a permanent home, a small library, with a supply of current journals, and the use of the larger libraries for reference books will greatly increase interest in the county organization.

9. Arrange the time of meeting to accommodate the largest number of members. When men come from long distances, an evening session is obviously the most inconvenient. An afternoon session will often appeal to a larger number of men when it permits them to reach their homes at a seasonable hour.

10. Select as officers men who are willing to work. Keep good men in office. Do not promote those who have shown that they will not attend to the duties assigned them. Efficiency is the only criterion of leadership. No physician should accept office unless he is prepared to give the position the attention that it deserves, and unless he is interested in the work.

11. In small societies do not unduly multiply offices—the secretary's and treasurer's duties can be best done by one man.

12. Make dues large enough to warrant conducting the society work in a proper manner.

13. Provide a committee on entertainment which shall welcome new or prospective members or guests at meetings. The officers of the society may be active or ex-officio members of such committee. Newly registered physicians should be visited by such committee or written to and asked to join the county society.

14. See that the meetings, programs of proceedings are published regularly and promptly in the state journal.

15. Have high ideals. Be liberal yet firm in the maintenance of a high ethical standard. Educate the public. Be a power for good in the community. Do not be ashamed of the county society or apologize for it. Make it better. Attend all meetings and see that others do the same. The county society is a conservator of patriotism and worthy citizenship.

Animal Experimentation

Dr. Carr, of New York City, offered the following resolutions:

Resolved, That the members of the House of Delegates do hereby declare that animal experimentation in this state is conducted in a proper and merciful manner, and that such experimentation is positively essential to medical progress; that unmerciful experimentation is not practiced in this state and is prohibited by law.

Resolved, That Senate Bill No. 310, calling for the investigation of vivisection in this state is therefore unnecessary and mischevious and calculated to hinder and interfere with vivisection, and correspondingly lessen the humane benefits derived therefrom.

Resolved, That we respectfully petition the legislature to express decided disapproval of all measures coming before it opposed to animal experimentation for the purpose of medical advancement; also all measures calculated to hinder or destroy the same.

These resolutions were adopted unanimously.

Membership in State and National Organizations

Dr. E. LeFevre, of New York, offered the following:

Whereas, The Board of Trustees of the American Medical Association has requested an expression of opinion on the subject of making in the future all members of state societies and county societies in affiliation with them *ipso facto* members of the American Medical Association, and in order that the board may make a satisfactory report to the House of Delegates of the national organization relating thereto, be it

Resolved, That the foregoing request of the Board of Trustees of the American Medical Association be referred to a committee of five, to be appointed by the president of this society for investigation as to the legality, expediency and advisability of the proposition, and to report to this House of Delegates at the next annual meeting.

On motion, the resolution was adopted.

The President appointed on this committee Drs. E. LeFevre, New York; S. B. Ward, Albany; W. W. Skinner, Geneva: J. C. MacEvitt, Brooklyn; and Wisner R. Townsend, New York.

Vaccination of School Children

Dr. D. S. Dougherty, of New York, offered the following resolution, which was adopted:

Whereas, There is a bill in the assembly known as Bill No. 611, designed to allow unvaccinated children to attend school on presentation of a physician's certificate that such pupil's or person's physical condition is such that vaccination will jeopardize his or her health, or on a written declaration from the parents or guardians of such pupils or persons to the effect that such parents or guardians are conscientiously opposed to vaccination; therefore, be it

Resolved, That this society protests against the passage of this act as inimical to the best interests of the state, and respectfully urges the legislature to withhold its approval of the measure.

Medical Education and Medical Practice Act

The following resolutions were adopted:

Resolved, That the Board of Regents of the University of the State of New York be requested to recommend such change in the medical practice act as will raise the requirements for securing the medical student's certificate to include, in addition to the standard high school course, one year in college, or its equivalent, embracing especially the following subjects: physics, chemistry (inorganic and qualitative analysis), and general biology.

Resolved, That the state society recommends to the Board of Regents that an investigation be conducted in order to ascertain the number of internships available in the hospitals of the state with a view to recommending a fifth year in hospital for the completion of the medical curriculum.

Registration of Midwives

Dr. Bernard Cohen, of Buffalo, offered the following resolution, which was referred to the council:

Whereas, In the larger cities in the State of New York nearly half of the births are attended by midwives, many of whom are wholly untrained for the responsible work which they assume, therefore, be it

Resolved, That the Erie County Medical Society favors the adoption of an educational standard similar in character to that which is now provided for trained nurses, and that it recommends the state medical society take such action as may lead to the establishment of a standard, the requirements of adequate examinations, with universal registration of all midwives practicing in this state.

Optometry

Dr. H. W. Wootton, of New York City, presented the following preambles and resolutions, which were referred to the council with power to carry out the recommendations:

Whereas, A law is now on the statute books creating a special class of practitioners known as optometrists, and

Whereas, This law gives to certain persons the right to adjust lenses to eyes with defects of vision and prohibits the use of drugs in determining the need for and the kind of lenses to be prescribed, and

Whereas, It is the opinion of the medical profession that a knowledge of the subjects taught in medical schools is absolutely essential for the proper and safe performance of the work this law gives opticians the legal right to do, and

Whereas, The entrusting of work so important to the hands of a class of people inadequately equipped, and who are denied the right to use the means necessary to do properly the work they are authorized to do, is a positive menace to the community; therefore, be it

Resolved, That it is the judgment of the Medical Society of the State of New York that the legislature made a serious mistake in enacting this law; that in the judgment of this society the legislature should be respectfully petitioned to repeal this iniquitous law; that in the judgment of this society Columbia University has taken a decided step backward in establishing a course in optometry in its extension teaching, advertising the same as an opportunity for men and women with only two years of high-school training to enter a "new profession."

Resolved, That Columbia University by creating this department and granting certificates of proficiency to students who fulfil its requirements not only discredits its own medical department but discriminates against its medical graduates, of whom is required a preliminary training far in excess of that required of the optometrist, which discrimination is especially intensified by the fact that the medical graduates who take up the practice of ophthalmology come in direct competition with graduates in optometry.

Resolved, That Columbia University by establishing this course in optometry has given support to a horde of incompetents who are constantly endeavoring to tear down the barriers created by the state for the protection of the public health, as is attested by the fact that the action of Columbia University in this particular is being advertised all over the United States by opticians seeking identical privileges elsewhere.

Resolved, That in view of the foregoing statements the medical society of this state respectfully urges Columbia University, in the City of New York, to abolish its course in optometry.

Officers Elected

The following officers were elected: President, Dr. Wendell C. Phillips, New York City; first vice-president, Dr. Peter W. Van Peyma, Buffalo; second vice-president, Dr. William F. Campbell, Brooklyn; third vice-president, Dr. C. R. Hervey, Oswego; secretary, Dr. Wisner R. Townsend, New York City, re-elected; treasurer, Dr. Alexander Lambert, New York City, re-elected; delegates to American Medical Association: Dr. A. T. Bristow, Brooklyn, Dr. J. W. Fleming, Brooklyn, Dr. Wesley T. Mulligen, Rochester, Dr. Henry L. Elsner, Syracuse, Dr. Edgar A. VanderVeer, Albany, and Dr. E. E. Cornwall, Brooklyn; alternates, Dr. S. W. S. Toms, Nyack, Dr. A. Walter Suiter, Herkimer, Dr. W. B. Handbidge, Ogdensburg, Dr. J. C. MacEvitt, Brooklyn, Dr. W. W. Strang, New York City, and Dr. Otto Pfaff, Oneida.

Albany was selected as the place for holding the next annual meeting, and the time April 16-17, 1912.

(*To be continued*)

TENNESSEE STATE MEDICAL ASSOCIATION

Seventy-Eighth Annual Meeting, held at Nashville, April 11-13, 1911

The President, Dr. John A. Witherspoon, in the Chair

The officers elected were named in The Journal, April 22, in the News Department.

Radium

Dr. G. P. Edwards, Nashville: In my experience, covering a period of nearly seven years, I have observed the action of radium in a great many different conditions and have gained confidence in its virtue. In thirty-eight cases of cancer of the lip, twelve of which were postoperative, there were thirty-one cures and six failures; one patient failed to report results. In seventy-six cases of cancer of the face, nine of which were postoperative, one patient failed to report, in one the radium failed, and seventy-four patients were cured. Eight recurrences yielded to treatment. In seventeen cases of cancer of the eyelids, nine involving the mucous margin, six the canthus, and two the skin, cures were effected. In eight cases of cancer of the breast there were three failures and five cures. In three cases of cancer of the nipple, there were one failure and two cures. In four cases of lupus vulgaris, all the patients were cured. Of seven patients with lupus erythematosus, six were cured. Of nine individuals with cancer involving the buccal spaces, gum, or mouth, six were cured. Three cases of cancer of the scalp terminated in recovery in all. Of two patients with cancer of the antrum, one recovered; of six with cancer in the nares, five recovered. In one case of cancer of the umbilicus a cure was effected, and also in thirteen cases of cancer of the neck. Six cases of cancer of the hand all resulted in cure. This report does not include patients now under treatment, nor does it include those cases in which the *x*-ray was used in conjunction with radium except when the radium was used subsequent to *x*-ray failure.

DISCUSSION

Dr. G. C. Savage, Nashville: I saw the case of malignant growth in the nasopharynx. The growth was removed, and it was one of the bloodiest operations I have ever seen. Radium treatment followed its removal, and the patient is now well at the end of eight or ten weeks. Another patient with sarcoma of the nasopharynx came under my observation, but was not operated on. Radium was used. There had been hemorrhage every day from the malignant growth, but under the use of radium by Dr. Edwards this patient is now fairly robust. There are no longer hemorrhages, and there is free use of the respiratory passages.

Significance and Surgical Treatment of Uterine Displacements

Dr. R. M. McCowan, Knoxville: In treatment of uterine displacements there are a few principles that appeal to me more strongly than others. These are: 1. The perineum must be looked on as the most important feature for consideration, for without perfect support here, anything one may do is futile. There are many operations that are suggested for repair of the perineum; I prefer the modified Tait. 2. Next in importance is the correction of the angle between the uterus and the vagina. This is accomplished by shortening the round ligaments, lifting the uterus forward and upward. When the anterior portion of the ligament is especially weak, I have found the modified Gilliam, Mayo and Fowler operation satisfactory. This consists in pulling the inguinal portion of the round ligaments through the outer border of the recti, and stitching them together on the anterior portion of the muscle. Another method which I have used for several years is one suggested first by S. M. Miller, of Knoxville. It consists in lifting the uterus upward and forward through an abdominal opening, until the round ligaments are brought into view; an incision is carried through the parietal covering along the long axis from the uterine end a variable distance toward the pelvic wall, in accordance with the relaxation present; the fibers of ligaments are then separated the length of the incision, and the halves, together with the attached peritoneal covering of broad ligaments, are drawn apart. The distal and proximal extremities are brought together by a suture passed through the tissues beneath the cuts from just beyond one extreme to the other. A single lateral suture on either side the central will close the incision in a transverse line and shorten the ligaments to the extent of the primary incision. In prolapse, the operation of selection is that suggested by Crile. It consists in tying off the ovarian arteries and in doing a supravaginal hysterectomy, leaving a long fan-tail leaf on either side of the body of the uterus; these are brought through the recti on each side and stitched together in the same manner as in the round ligament operation. The greatest difficulty in dealing with these cases is the fact that often there is an existing general visceroptosis. In anterior displacement, usually a complete dilatation of the cervix is all that is required with a pulling down and stretching of the ligaments, or a wedge-shaped portion of the cervix may be removed from the posterior portion, as has been suggested by Dudley.

DISCUSSION

Dr. R. Caldwell, Nashville: I have found as many retrodisplaced uteri in women who have not borne children as in child-bearing women, and yet so far as we could determine, in those women the perineum was normal. I am inclined to believe that if we can maintain the normal position of the uterus by means of the ligaments or guy-ropes, and maintain the proper angle, and bring the uterus forward, we will prevent retrodisplacements.

Dr. C. N. Cowden, Nashville: Not every woman with a backward displacement of the uterus should be subjected to operation, because women are not all of the same nervous temperament, and while a backward displacement in one patient will create enough nervous disturbance to warrant an operation, in other instances such an operation would not be required. We must individualize in these cases before we can ever apply the rule in a sensible way.

Traumatic Perforation of Abdominal Viscera

Dr. W. M. McCabe, Nashville: Within the last eighteen months I have had the following cases of injury to the abdominal viscera: One gunshot perforating wound, the patient dying. Eight gunshot perforating wounds with bullets, four of which required resection; seven of the patients recovered. There were two gunshot-wounds of the liver, one operated on, and one not operated on; both patients recovered; one penetrating gunshot-wound; three stab wounds of the stomach through the left interspaces; four stab wounds of small intestines; one stab wound of ascending and transverse colon; one stab wound of the spleen; three penetrating stab wounds. All patients with stab wounds recovered. I believe that as a rule the median abdominal incision is preferable in gunshot wounds, but occasionally vary this procedure. I do not hesitate to make a subsequent incision if it will facilitate matters and allow of more thorough and satisfactory examination. If resection is decided on, I clamp the gut, take out a triangle of mesentery, and control the hemorrhage. A Connell suture of linen is then inserted at the mesenteric border, and this suture is run continuously around the gut, going through all coats. This part of the anastomosis is completed by suturing the rent in the mesentery with the same thread. This suture is covered with a Czerny-Lembert suture in the peritoneum, and reinforced with catgut, if necessary. I am careful to make the suture approximate, but do not allow it to constrict. I now examine the work, invaginate the bowel through the anastomotic ring, and if the thumb and forefinger meet I am satisfied. If only perforations are to be dealt with, I put in a purse-string suture of linen, if it does not constrict the lumen too much, or suture with a through-and-through linen suture and cover with a Czerny-Lembert of catgut or linen. The perforations having been closed, I wash the intestines with saline solution and drop them back into the abdominal cavity. The peritoneal cavity is then sponged out with gauze sponges; I never flush the cavity with any kind of solution. I have sponged away pumpkin seeds, tomato skins, feces, and other matter, and have yet to regret that I did not flush the cavity. If there has been much soiling of the peritoneum, I insert a drain. I should be delighted if the drain could be dispensed with, but as yet I have not been sufficiently convinced that it is a useless procedure. I have learned, however, that all drains produce necrosis of the abdominal wall, and for this reason they should always be brought through a separate stab, thus allowing the abdominal incision to heal by first intention and preventing hernia and other complications.. The patient is placed in bed in the Fowler position, the Murphy drip enema is given constantly, and all food and water is withheld for twenty-four hours. Purgatives are not given for at least five days. *This treatment is not* carried out unless I suspect that peritonitis is liable to occur. While I have done the end-to-end anastomosis with success, I believe the lateral method is safer and may use it hereafter.

DISCUSSION

Dr. W. D. Haggard, Nashville: The meeting of the Southern Surgical and Gynecological Association in this city in 1896 marked the first crystallization of the expression of immediate abdominal section for every penetrating abdominal wound. It was the sense of that body that immediate exploration should be the rule in all cases of gunshot and stab wounds of the abdominal viscera, and since then I think this has been the opinion of most surgeons, and also that if we should fail to do this and peritonitis should occur, and we are powerless to control it after eight hours has been permitted to elapse, we have been guilty of a grave error. I think, sometimes, that in the future this may assume a medicolegal aspect. I do not feel that we should shirk moral responsibility in these cases, to say nothing of surgical responsibility. As a matter of fact, we have two lives in our hands—the life of the victim, and the life of the assailant. Dr. McCabe has reported an unusual group of cases, with a satisfactory rate of mortality, and the lesson we ought to learn is to suspect every penetrating wound of the abdomen to be a perforating one, and never rest contented until we see inside the abdomen and repair thoroughly every wound after having gone over every inch of the viscera.

Dr. J. L. Crook, Jackson: One remarkable thing in cases of this character is the improved mortality within the last five years. The point made of using a stab wound for a drain is a good one, whether operating for perforation of the intestine or for other purposes. If we can make drainage through a separate incision, we can get a better result than by draining in some cases through the original wound.

Dr. J. A. Gaines, Nashville: One of our greatest authorities on duodenal ulcer, Moynihan, suggested that when there is perforation, especially when there are beans, lettuce, cabbage and things of that character in the abdominal cavity, another opening should be made and the abdomen flushed. I do not believe that we should make such an opening for the purpose of flushing out things of that character. Flushing should not be done; we should pick out these things, and clear out the foreign material as well as we can by mechanical applications, without flushing the abdomen, and using drainage in all cases of this character.

Dr. L. L. Sheddan, Knoxville: I have observed that stab wounds are simpler than gunshot-wounds. I have seen two patients die because in closing the perforation the peritoneum was not closed a sufficient distance around the margin of the wound. Again, paralysis is more likely to follow an injury from a gunshot-wound than from a knife of a stab wound. The author of the paper said that in injuries of the liver, the liver does not bleed very much. It has been my observation that it bleeds very profusely when injured.

Cancer of the Breast

Dr. H. M. Tigert, Nashville, advocated surgical treatment for the relief of this condition.

DISCUSSION

Dr. L. E. Burch, Nashville: According to the statistics of the United Kingdom, one woman out of every twelve in the year 1908 died of cancer, and in the State of New Jersey last year more people died from cancer than from tuberculosis. The only way to effect a radical cure of this condition is to make an early diagnosis and operate promptly. Every tumor of the breast in a woman above the age of 35 should be removed and examined.

Dr. B. Malone, Memphis: There is great diversity of opinion as to the etiology of cancer. In Rome practitioners have reverted to the Cohnheim embryonic theory of cancer. They are using an emulsion of embryos in the treatment of cancer in the experimental laboratories there, and while they are not making many claims, the results have been encouraging. Dr. W. J. Mayo, who saw some of this work while he was abroad, says that in his opinion it promises more than anything else in the way of a specific cure for this disease.

Dr. J. M. King, Nashville: Every tumor of the breast should be removed before *x*-ray treatment is resorted to. I do not think any one should apply the *x*-ray treatment to a tumor of the breast unless it has recurred.

Dr. E. T. Newell, Chattanooga: I have had two cases which showed that tumors of the breast occurring in women over 35 are not always malignant. One patient has gone five years since the removal of the tumor without recurrence, and the other three years without recurrence.

Dr. McPheeters Glasgow, Nashville: In tumors of the breast occurring in young people it is advisable to remove the breast at once, but in a woman over 50 it might be well to watch the case carefully before advising operation. Certainly, operation should not be advised on seeing the patient once or twice.

Dr. W. T. Black, Memphis: Early extirpation is the only remedy, and all tumors of the breast should be treated as malignant unless they are proved to be benign.

Dr. J. Overton, Nashville: I think that we should use Coley's fluid in cases of inoperable cancer, unless some serum of more pronounced value is brought to the attention of the profession in the meantime.

Dr. W. Litterer, Nashville: It is important to examine the axillary glands in cases of cancer from a prognostic standpoint.

Dr. C. A. Robertson, Nashville, spoke of metastases in cancer of the breast, and detailed a very interesting case which came under his observation within the past eighteen months.

Dr. W. H. Witt, Nashville: In two cases in my practice, the disease recurred after ten years in one, and in the other after seven years. These recurrences were metastatic in nature. One patient died two or three months following the recurrence.

Spina Bifida

Dr. B. B. Cates, Knoxville: I previously reported three cases of spina bifida operated on, with one death. Since publishing this report, I have operated on four other patients with one death, making a total of seven operations with two deaths. There were five males and two females. The ages varied at the time of operation from 28 days in the youngest to 26 years in the oldest. The situation of the tumors was in the cervical region once in a female, twice in males; once in the lumbar region in a male, once in the lumbosacral region in a male, once in the upper sacral region in a male, and once in the mid-sacral region in a male. One step in the technic of the operation concerns the closure of the spinal defect with osteoplastic grafts. In not one of my cases was there enough bone at hand to cover the opening, so I used the deep fascia, by dissecting enough from without inward to cover over the defect when turned over the middle line. This fascia is strong and dense enough to form a strong bridge. It is not necessary to overlap the flaps, simply stitching the edges together with fine catgut being all that is necessary. I think that I caused necrosis in one case by imbricating the flaps, thus cutting off the blood-supply.

DISCUSSION

Dr. J. L. Crook, Jackson: I have had two cases of spina bifida under observation. In one of these the child was so weak that I did not think it would survive an operation, hence I did not operate. The other child was 8 months old and had a meningocele in the lumbosacral region, on which I operated successfully.

Dr. B. Malone, Memphis: My experience also is limited to two cases. In one, there was a meningomyelocele, and the other was a pure meningocele. In meningomyelocele, in which the sac is composed of cord elements, the prognosis is unfavorable.

Dr. R. Caldwell, Nashville: Attention should be given to the association of spina bifida with hydrocephalus. When this is the case, very little can be expected from operation, as these patients become hydrocephalic and die from exhaustion and imbecility after a few years of life.

(To be continued)

Book Notices

Differential Diagnosis. Presented Through an Analysis of 383 Cases. By Richard C. Cabot, M.D., Assistant Professor of Clinical Medicine, Harvard University Medical School, Boston. Cloth. Price, $5.50 net. Pp. 753, with 195 illustrations. Philadelphia: W. B. Saunders Co., 1911.

Cabot proposes to study medicine from the point of view of the presenting symptom, by the case-history method. Cases are grouped according to the chief symptom, such as headache, lumbar, abdominal or epigastric pain, fevers, chills, coma, convulsions, cough, hematuria, jaundice, etc. Each section is prefaced by a statement of the possible causes of the symptom under discussion. Illustrative cases follow, in which the salient points in the history, examination and laboratory findings are given, the differential diagnosis discussed, and diagnosis made. Numerous plates showing the distribution of pain, physical findings, etc., accompany the case histories. Diagrams are given, showing graphically the relative frequency of the several diseases in which any one symptom may be the principal complaint. These are based on hospital records and at times may be misleading to the general practitioner who sees a less selected series of cases.

Cabot is no respecter of traditions and, as occasion presents, criticizes those which he believes are not founded on facts—e. g., the relation of backache and pelvic disease, tapeworm and abdominal pain, poor teeth and digestive disturbances. It is perhaps superfluous to conduct obsequies over "rheumatism" and "gastralgia," as they have been buried already by most of the profession. The importance of lead intoxication as a cause of many obscure symptom-complexes is rightly emphasized. The cases cited in illustration of abdominal and epigastric pain are particularly instructive.

In many instances the diagnosis is arrived at through an admirable course of reasoning. We may, however, question the advisability, even for teaching purposes, of arbitrarily placing difficulties in the way of diagnosis by the suppression of facts which are obvious on careful examination. A diagnosis made in spite of omissions deserves no special credit. We may also question certain diagnoses in that they are made on insufficient evidence, or the resources of diagnosis are not all utilized. Abdominal pain is frequently caused by constipation, but to dismiss a case with this unreserved diagnosis after a short period of observation may be dangerous, in view of the frequency with which carcinoma presents the same symptoms. It is, however, easier to criticize a diagnosis than to make one, and the general impression made by a case often has a weight which cannot be conveyed by verbal expression.

Typographic errors are few. Kernig's sign is repeatedly referred to as "Koenig's" sign.

The chief value of "Differential Diagnosis" lies not in the introduction of new facts, but rather in the demonstration to the student of the manner by which he may arrive at a reasonable diagnosis by careful observation and proper correlation of the facts obtained from the history, physical examination and laboratory findings. To the practitioner also, who would go beyond the mere treatment of symptoms, or learn of the difficulties surmounted by another, this book will prove of great interest and value.

Vaginal Celiotomy. By S. Wyllis Bandler, M.D., Fellow of the American Association of Obstetricians and Gynecologists. Cloth. Price, $5 net. Pp. 443, with 148 illustrations. Philadelphia: W. B. Saunders Co., 1911.

In this valuable work the author has very clearly stated the technic of vaginal operations and amplified them with comprehensive illustrations, so that the various surgical procedures are made perfectly clear. Even though the reader has had no personal experience with the vaginal route, he can hardly fail to see its advantages and the great field it offers in certain stated gynecologic operations. The history of anterior vaginal celiotomy is clearly outlined and beautifully illustrated and the possibilities and the indications are so accurately described that one is fully impressed with its value, while the comparative advantages of the vaginal over the abdominal route are succinctly expressed. The technic in anterior vaginal celiotomy is clearly outlined, and, although the author has fully impressed the reader with its difficulties, he encourages those who are not familiar with the route to become acquainted with it. The positive indications for conservative operations on the ovaries and tubes, retrodeviations of the uterus, and cystocele, are tersely given. Added to the subject of total uterine prolapse is the technic of the amputation of the cervix, which is an important evolution in the operative procedure for permanent correction of procidentia. The description of vaginal hysterectomy, myomectomy, vaginal Cesarean section, metreurynter incision, and minor vaginal Cesarean section, makes this volume a complete summary and the most comprehensive work in vaginal operations that has been published. It is invaluable to the gynecologist, the surgeon, and the obstetrician, as well as to every physician who desires to be intelligently informed on the late and advanced methods of gynecologic surgery.

Photographic Atlas of Radiography of the Mastoid Region and of the Nasal Accessory Sinuses. By Joseph C. Beck, M.D., Clinical Professor of Oto-Laryngology, College of Physicians and Surgeons, University of Illinois. Half Morocco. Price, $8. St. Louis: The Laryngoscope Co., 1911.

This loose-leaved atlas, so constructed as to permit changes to be made in the radiographs it contains, has been compiled by Dr. Beck with the cooperation of a radiologist and a photographer. To avoid marking the photographs which have been used, half-tones being unsatisfactory, the author follows the scheme of using an outline drawing to explain the radiograph after the manner of Killian's "Atlas on Face Reproduction." The importance of following the technic, which is fully outlined, is emphasized. Three positions are suggested: The postero-anterior position shows the frontal sinuses, ethmoids, orbits, and the antra and nasal cavities; the lateral position, the sphenoidal sinuses, the sella turcica and the depth of the frontal; the mastoid position is limited to use in studying the mastoid, the middle ear and the lateral sinus. These positions permit of the study of fractures and diseases of the bones and of foreign bodies, as well as the condition of the sinuses. The photographic methods that have given best results are explained. Eight stereogram illustrations are presented; four showing the positions described, three radiographs of a skull taken in the different positions, and one the difference between a stereoscopic and pseudoscopic image as shown in Dr. Kelly's atlas. Then follow twenty-five photographs, 19 cm. by 24 cm., from radiographs of the skull and of the head, showing the normal and certain abnormal conditions of the sinuses and some results of faulty technic.

The purpose of the atlas is to aid in the interpretation of radiographs of the head. To the degree that it is accepted as establishing a standard of technic, it will attain its object.

Serum and Vaccine Therapy. Bacterial Therapeutics and Prophylaxis Bacterial Diagnostic Agents. By R. Tanner Hewlett, M.D., F.R.C.P., D.P.H., Professor of General Pathology and Bacteriology, King's College, London. Second Edition. Cloth. Price, 7 shillings 6 pence net. Pp. 406. London: J. & A. Churchill, 7 Great Marlborough Street, 1910.

The first chapter of this book is taken up by an introductory consideration of the principles underlying immunity processes in general. The preparation and practical application of the various antitoxic and antimicrobic serums are then concisely described. The section of the book dealing with the principles of vaccine therapy, and giving practical directions for preparation and use, is especially valuable. Hewlett's views concerning direct transfusion are somewhat at variance with the prevailing American ideas and the subject is therefore dismissed with but slight consideration. The references to important literature on the different subjects constitute a valuable portion of the book.

Tuberculosis of Farm Animals. Bulletin 149, University of Illinois Agricultural Experiment Station. By Charles F. Briscoe and W. J. MacNeal. Urbana, Ill., February, 1911. Paper. Pp. 431.

This bulletin contains a splendid summary of the findings of experimenters and investigators in this and foreign countries concerning tuberculosis in farm animals, especially with reference to its transmission by means of the bovine form of the bacillus to human beings through the various channels. It also contains the results of the study and experiments at the University of Illinois Agricultural Experiment Station, together with an extensive bibliography relating to this line of work.

Medicolegal

Evidence Which Dead Body Cannot Be Made to Furnish

The Supreme Court of New York, Special Term, Erie County, holds, in the case of Danahy vs. Kellogg (126 N. Y. S. 444), that no right of exhumation, inspection, dissection, microscopic examination, and taking of culture is furnished in a civil action by the code provision in that state that a court of record has power to compel a party to make discovery of any article or property in his possession or under his control relating to the merits of the action or of the defense therein.

In this case was the first application of the kind ever made, so far as the court is aware. The action was brought by the administratrix of the estate of Matthew Danahy, deceased, to recover damages for his death, alleged to have been caused by injuries received in a collision with an automobile claimed to have been owned by the defendant. The accident occurred July 10, 1909, and the death of Danahy on November 20, 1910. The certificate of death signed and filed by the attending physician stated the cause to have been malignant endocarditis. The discovery and inspection of the body, with permission to take cultures and to have microscopic examinations made, it was alleged, would furnish the means of determining the exact cause of said disease.

The denial of the application was based squarely on the absence of any right or authority in the court to grant the inspection, etc., asked, notwithstanding the provision in the code above mentioned. In considering the latter, the court is sure that the legislature could not have had any intention to include the body of a dead person within the description of an "article" or "property," or have had in mind an application to exhume the remains of a deceased person for the purposes of the section. But, even though it authorizes an order for the production and inspection of a buried human body, the court finds nothing in the section which could possibly authorize its dissection, etc. If the article to be inspected were a piece of machinery, instead of a human body, the court, under the section relied on, would not be warranted, it thinks, in making an order permitting the machinery to be taken apart, and a part of it carried away for the purposes of further examination. Much less would the court be justified in permitting an autopsy on a human body.

There is, strictly speaking, no right of "property" in a dead body. A long line of judicial decisions appear to have established the general doctrine to that effect, although the law has been relaxed to the extent of giving the husband, widow, or next of kin the right of protecting the remains of the dead and saving them from desecration, which can be enforced by appropriate legal remedies.

Validity of City Ordinance Requiring Tuberculin Test

The Supreme Court of Wisconsin, in Adams vs. City of Milwaukee and others (129 N. W. R. 518), holds valid a city ordinance requiring the tuberculin test, and that there was no error in a judgment against enjoining the enforcement of the ordinance. It says that it is not necessary to support the ordinance to show that human pulmonary tuberculosis is caused by drinking the milk of cows afflicted with bovine tuberculosis. If the milk of such cows produces disease of any kind, or is harmful to health, this is a sufficient basis for police regulation of its sale and distribution in the city.

Attention was called to chapter 542, Laws of Wisconsin for 1909, and to the following statutes of other states, recognizing the efficiency of the tuberculin test: Indiana, chapter 181, Laws 1909; Delaware, chapter 122, Laws 1909; Maine, chapter 133, Laws 1909; Maryland, chapter 466, Laws 1910; Michigan, chapter 172, Laws 1909; Minnesota, chapter 392, Laws 1909; New York, pages 28, 29, vol. 1, Consol. Laws 1909; North Dakota, chapter 160, Laws 1909; Oregon, chapter 213, Laws 1909; South Carolina, chapter 131, Laws 1909; South Dakota, chapter 291, Laws 1909; Tennessee, chapter 475, Laws 1909; Vermont, No. 1, chapter 163, Laws 1908; Virginia, chapter 335, Laws 1910. The court was also referred to the cases of State vs. Nelson, 66 Minn. 166; Nelson vs. Minneapolis (Minn.), 127 N. W. R. 445; and New Orleans vs. Charouleau, 121 La. 890.

The evidence and findings in the present case, this legislation, and these decisions, go to show a widespread recognition of the danger of infection from bovine tuberculosis and of the efficacy of the tuberculin test. When there are conflicting scientific beliefs or theories in such matters it is for the city council to determine on what theory it will base its police regulations, and unless it is clearly and manifestly wrong it is not for the courts to interfere on the ground that the scientific theory on which the ordinance is based is incorrect or unsound.

Nor does the court consider that the ordinance is rendered void because it applies only to dealers in milk drawn from cows outside of the city, when there are other regulations covering the sale of milk drawn from cows kept within the city. There is a sufficient basis for such classification in the difference of facility for inspection and regulation.

Furthermore, the court thinks that a situation was disclosed in which it might be said that the common council had the right to decide that destruction of the milk was the only available or efficient penalty for the enforcement of the ordinance, and that such destruction was necessary, and the ordinance cannot be declared unreasonable in this particular. Then the plaintiff himself must by his own act expose his property to confiscation before this portion of the ordinance will affect him injuriously, and there is a distinction recognized in some cases between preexisting nuisances and those created by wilfully placing property in the forbidden place or condition after the enactment of an ordinance, and in defiance of it. Self-inflicted damage is not recoverable.

Who Accounted "Physicians Now Registered" Under Medical Practice Act

The Supreme Court of Missouri, Division No. 2, holds, in State vs. Carson (132 S. W. R. 587), that, as the defendant was concededly registered and licensed under the Missouri act of 1877, he came squarely within the exception to the act of 1901, as "a physician now registered," and that no subsequent act of the Missouri legislature has revoked the license given him under the act of 1877, so that it was error to require him to have been also licensed by the board of health.

The court says that, after the defendant was duly registered under the act of 1877, namely, in 1880, by filing a copy of a diploma, the legislature passed the act of 1883, which provided that it should not apply to those who had been practicing medicine five years in that state prior to the enactment of that law, but contained no provision as to prior registration. Then came the act of 1901, making it a misdemeanor for any person, "except physicians now registered," to practice medicine or surgery without a license from the State Board of Health. The trial court held that a physician registered under the act of 1874 was a registered physician within the meaning of the law of 1901, and a physician registered under the act of 1877, five years before the act of 1883 went into effect, would be registered within the purview of the law of 1901, but, inasmuch as the defendant was not registered until 1880, less than five years before 1883, he was not a registered physician within the meaning of the law of 1901, which last conclusion was erroneous.

The construction which the state sought to have given the act of 1901 would necessitate the court amending the statute so that it would read: "Any person, except physicians now registered and qualified to practice under the laws of 1883." The defendant was not prosecuted for a violation of the act of 1883 while it was in force. That act was, in turn, repealed by the act of 1901, and five years' practice no longer afforded protection. Thus if a physician had practiced five years before 1883, but was not registered, he would clearly fall under the condemnation of the act of 1901 because he was not registered. What effect then had the act of 1901 on the registration of the defendant's diploma and certificate in 1880? The diploma was registered under the law of 1877, and no subsequent act required or permitted it to be registered again. While it might or might not have protected him from prosecution during the life of the act of 1883, what was there to prevent the legislature repealing the act of 1883 as it did, and providing that his registration under the act of 1877 should protect him from prosecution and permit him to continue his practice? No act of the legislature had revoked the license the state had granted him in 1880, and no tribunal authorized to do it had done so. Even if it should be said that the act of 1883 impliedly rendered his registration ineffective, it cannot be doubted that the legislature could restore its efficacy by express provision as it did in 1901. This court is unable to see any substantial reason why a physician registered under the act of 1874 should be within the exception to the act of 1901, and one registered under the act of 1877 under the broad language of the exception of the act of 1901 does not also fall within the act of 1901.

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

April 13

1 *An Analysis of Forty-Six Cases of Prostatectomy. L. Davis, Boston.
2 *Vaccines in Puerperal Sepsis: W. H. Watters and C. A. Eaton, Boston.
3 *Intrathoracic Insufflation Anesthesia: Apparatus and Cases. A. Ehrenfried, Boston.
4 Extirpation of the Tonsil by Enucleation: Partly Instrumental, Partly by the Use of the Finger. L. M. Freedman, Boston.

1. **Prostatectomy.**—A summary of the results obtained in the twenty-four cases of perineal prostatectomy reported by Davis, shows that two patients died; in neither case was death directly due to the operation. All the others left the hospital in good condition with obstruction relieved. In fifteen cases, the end-results have been excellent in every respect—all that could be expected or desired. In two other cases the result is marred only by the loss of sexual power. One patient has a persistent cystitis which is symptomatically controlled by regular treatment; otherwise he is well. In four cases the results are not so satisfactory. In one there is poor control of the bladder, so that the patient prefers to wear a urinal. In another there is, at times, under stress, lapse of control. Two patients have persistent perineal fistulæ; in one of these there is also some cystitis.

Of the twelve patients operated on by the upper route, two died. One patient, in whom the complication of closure of the bladder outlet during convalescence occurred, requiring a secondary operation, has not been traced since discharge. There is no reason why the final result should not have been satisfactory, however. In one case in which the suprapubic operation followed an unsuccessful partial perineal prostatectomy, by another surgeon, Davis says that the incontinence which followed unquestionably would not have occurred if the external sphincter had not been injured in the first operation. In the eight remaining cases the functional results were excellent. Two patients have died since leaving the hospital, one three months afterward of pneumonia, one four years later of new growth of bladder; in neither were there any symptoms on the part of the prostate. Six patients have recently reported themselves alive and well without urinary symptoms. Data as to amount of residual urine are unfortunately meager; several of the patients lived at considerable distances and were able to report only by letter. In six cases in which it was recorded, the highest amount was 1½ ounces in a man who previous to operation had lived a catheter life for fifteen years; in the other five cases it was less than 1 ounce. As to sexual power, data are still scantier. Two patients are known to have retained it; in one patient who underwent both operations it was lost.

2. **Vaccines in Puerperal Sepsis.**—Fifty cases are reported by Watters and Eaton. This includes all patients who have been treated, the good and the bad, the early and the late. Among this series are a few who received ante partum prophylactic injection on account of bacteriologic findings or unusual opportunities for possible puerperal infection. These all recovered. It is of further interest that certain others who likewise received prophylactic treatment showed pure cultures of streptococcus in the uterus post partum, but without any clinical symptoms of sepsis or other complication. This was never noted in other normal patients not so treated. Among the fifty cases reported, four patients died within twenty-four hours of the first treatment, being practically beyond any hope of recovery when vaccines were first requested. Three others were moribund when inoculations were begun. Here life was possibly prolonged two or three days. Apart from these, there are forty-three patients, two of whom died and forty-one recovered. Of the two who died, one was operated on for suspected pus tube, which was not found, the patient dying six days after; the other was subjected to blood transfusion, dying within a few hours.

The method of using the vaccine was to administer a polyvalent preparation immediately after the diagnosis seemed definite, as determined by bacteriologic tests and to repeat as necessary until the autogenous preparation was ready, about twenty-four hours later. The vaccines were prepared by the use of the minimum degree of moist heat, a method apparently followed by better results than when the earlier method was employed. Careful watch was made to ascertain any possible injurious effects or aggravation, but even in the worst cases none could be demonstrated. On the contrary, a number of patients who seemed to be almost without hope of recovery made very happy convalescences. No claim is made by the authors that the vaccines should replace other generally recognized methods. On the contrary, they insist that the vaccines should be used to assist all other methods that have proved to be of value. In the series reported a hot vaginal douche has usually been employed; very rarely, in only one or two cases, an intra-uterine douche. Curettage was not performed in any instance. The bowels have been maintained in an active condition and remedies have been used when indicated. The authors have strongly advised leaving the patient as free from manipulation or local treatment as possible, and believe that the results well bear out these instructions. Two facts are given in conclusion: One that no demonstrable harm has been often done to any person; the other, that patients have shown much improvement after the inoculations and have recovered when even the best clinicians have foretold a fatal termination.

3. **Intrathoracic Insufflation Anesthesia.**—The apparatus Ehrenfried uses consists of a Wolff bottle with three necks sitting within a copper water jacket, and a foot bellows. By means of cocks on the outside of a jacket, the stream of air from the bellows can be carried through the hot water, over the top of the ether (contained in the Wolff bottle), or through the ether when a particularly strong vapor is desired. Air and ether vapor may be mixed in any proportion. Connected with the delivery end of the apparatus is a safety valve and pressure regulator consisting of a bottle of mercury into which a tube is plunged. The depth of the tube in the mercury, which is adjustable, represents the maximum of pressure which is allowed within the apparatus; if for any reason, such as a spasm of the glottis, the pressure should rise, the valve "blows off" automatically and danger from interstitial emphysema is avoided. In his early experiences, Ehrenfried employed a dial manometer registering in millimeters of mercury, to record the pressure, but he has found that the pressure bottle answers as well for all practical purposes. The apparatus is provided with a device to prevent droplets of condensed ether being carried over into the larynx.

The air or mixture is supplied at a practically constant temperature of about 10 degrees above room temperature; if the operation is to last over half or three-quarters of an hour the contents of the water jacket should be replaced. The air supplied may be filtered and moistened. For an intratracheal tube he uses a French lisle catheter, 22 to 24 F., moistened in hot water to render it pliable, a new and sterile one being used for each case. Soft rubber tubes have the advantage of standing sterilization by boiling better, but they are less easy to introduce. The chief difficulty with this method of anesthesia so far has been the introduction of the tube. He now uses a simple introducer, a laryngeal forceps with sleeves attached for grasping the tube near its extremity, similar in principle to the introducer of Doyen. After considerable pains to produce the proper curve—working on frozen sections and cadavers—Ehrenfried has devised an instrument which can be guided into the larynx in a few seconds, with the mouth gag in place and the left forefinger on the epiglottis, without the necessity of using a head mirror or electric illumination, or changing the patient on the table to and from the Rose position, as is necessary with the direct laryngoscope. Ehrenfried has tried this apparatus successfully four times on human beings.

5. **Posture as an Aid in Diagnosis of Cardiac Affections.**—It is for cases of extreme cardiac failure due to dilatation secondary to severe valvular disease or myocardial disease that Berg has found that a posture which is a combination of recumbency with vertical or semivertical position, forms a powerful adjuvant in the treatment. He has placed such patients in bed with the head of the bed raised, as in the Fowler position, but with the patient in what he calls the reversed Trendelenburg position. The patients lie on an inclined plane, body and legs extended, with the head and shoulders at the top and the feet at the bottom of the inclined plane. The posterior legs of the bed on which the patient lies are raised 4 to 24 inches from the floor, resting on chairs or wooden supports with a broad base and narrower top, shaped like truncated cones or pyramids, or by any other means that may occur to the physician or some ingenious relative. The full height of 24 inches should not be attained, however, at one stroke, but gradually, so that the patient may not get an annoying sense of insecurity from the unaccustomed attitude of lying on an inclined plane, down hill, as it were. At the foot of the bed the patient's feet should rest against a well-bolstered or padded wooden rest, which extends across the width of the bed. Well-padded boards, 15 to 18 inches wide, should bound the sides of the bed to prevent the patient slipping out during sleep.

The whole structure should be as firm as though the patient's bed were resting in the usual horizontal manner on the floor, in order to give the sense of security. The patient's head and shoulders should be supported by pillows and sometimes by a head rest. The body should lie recumbent on the bed in this inclined plane without any bend at the hips, so that the maximum downward effect of gravity on the liver and abdominal organs may be obtained. The upward pressure on the diaphragm is thus removed; the heart relieved by the increased space thus obtained, and the venous return in the portal veins, vena cava and pulmonary veins encouraged. Berg has seen patients suffering from cardiac failure as a result of dilatation complicating valvular disease and myocarditis, more especially when mitral regurgitation is an element of the valvular disease, immensely relieved of their dyspnea by this posture alone, even before other more direct therapeutic measures were applied.

8. **Erythremia.**—Brill's patient, in addition to an erythrocytosis of between 8,000,000 and 10,000,000 cells, a leukocytosis varying between 20,000 and 45,000 leukocytes, presented few features of a cyanosis, a much relatively diminished hemoglobin content, the color index being far below 1, showed marked signs of bone marrow involvement with a colossal spleen and a very large liver. The spleen was much larger than in other affections, excepting those found rarely in leukemia and more commonly in the Gaucher type of primary splenomegaly. But even in these affections Berg has never seen a larger spleen than this patient presented. From the clinical evidence, he says, one must conclude that this patient was suffering with the disease which has been variously called polycythemia with chronic cyanosis, splenomegaly, erythrocytosis, splenomegalic polycythemia, myelopathic polycythemia, erythremia, erythremia megalosplenica, Vaquez's disease, Osler's disease.

13. **An Unusual Case of Fracture.**—The subject of this report was a man, aged 70, who had always been remarkably active physically and mentally. He had been for years harrassed by a gouty eczema and had been treated for arteriosclerosis some years before. About seven months prior to the injury to be described, after a hard day's ride and tramp in the mountains, he had acute dilatation of the heart, from which he suffered up to the time of his accident, though he persisted in long rides and unwarranted exercise. About noon, Oct. 27, 1906, while riding, his horse stumbled. He was thrown, evidently striking on his forehead. There was immediate and complete motor and sensory paralysis below the neck without loss of consciousness. There was involuntary evacuation of the bladder and bowels at the time of the accident and again after being put to bed. By the use of moderate doses of morphin, the patient passed a fairly comfortable night, requiring catheterization; priapism was present. There was no difficulty in swallowing.

During four or five weeks following the injury he was catheterized three times daily and had no irritability of the bladder. From that time up to the time of his death he was catheterized from four to ten times in twenty-four hours, the frequency varying without apparent physical cause. He was given hexamethylenamin continuously during the twenty-eight months of his illness, in daily doses of from 10 to 30 grains. There were apparently no harmful effects from it unless it had to do with the constantly low solids in his urine during the last twenty-four months of his life. He never regained control of his bladder, though after three months he could reinforce the flow and a few times voluntarily passed 1 or 2 ounces. There was often marked tympanites and digestive disturbance, but, for the most part, the bowels were easily moved daily by laxatives and enemata. Occasionally there were loose involuntary movements. There were a number of periods of great weakness and mental hebetude, which were relieved by free elimination by the bowels. There seemed, at times to be an element of mental fatigue in this depression. Sleep was always difficult, requiring constant use of hypnotics. At the end of nine weeks the patient was up daily, taken out in a wheel-chair, and very soon was lifted into his automobile and was taking long rides. During the following year he often drove for five or six hours a day, with no apparent fatigue, was taken to a number of social functions in his own and adjoining towns, and took keen, active interest in all affairs of life. Mentally he was extremely active, at times giving close application to business affairs for six or seven hours a day. He became able to write short notes (writing by whole arm movement); could, without effort, feed himself by means of a spoon or by taking food in his right hand, and was often taken to the dining table, and about his house and grounds in his wheel-chair. He could move his legs to a considerable degree (the right leg and arm much more than the left) but could never stand or sit alone, nor was he ever able materially to change his position in bed without help. The heart at times showed a systolic murmur of the apex, but from the time of his injury was entirely competent.

At the end of eighteen months he had become more sleepless and depressed. He then went to England, making the trip very comfortably. During his six months' stay there he had an attack of bronchitis and lost ground in all ways, coming home in November, 1908, considerably weaker physically and less active mentally than when he left. During the winter he drove in his automobile almost daily, up to two days before his death, when he became uremic, and died March 13, 1909, twenty-eight and one-half months after his injury. The points of general interest in this case seem to be: (1) The marked mental activity and endurance of the patient; (2) prolonged excessively low solid content in the urine; (3) prolonged use of hexamethylenamin without apparent harm; (4) relief from long standing eczema; (5) the acquiring of compensation in a weak heart by enforced rest; (6) avoidance of bedsores and cystitis. The bodies of the fourth, fifth and sixth vertebræ were moderately crushed together without buckling of the spine or encroachment of its canal.

17. **Skin Sterilization by Iodin.**—The mixture used by McDonald consists of iodin, 2 parts; carbon tetrachlorid, 98 parts.

New York Medical Journal

28 Rôle of Acute Bronchitis, Exacerbations and Remissions in Pulmonary Tuberculosis. H. J. Hartz, Philadelphia.

26. **Duodenal Ulcer.**—In the case reported by Lynch the patient gave no history of any disturbance of digestion. Her pain was all referred to the region of the appendix, and the tenderness was confined to the same region. Later, Lynch elicited the fact that she suffered off and on from what she called indigestion; that she occasionally had pains coming on some four or five hours after eating; took something for relief, vomited and felt better after it.

54. **Hysteropexies.**—The object of Dickinson's paper is to encourage a broader study of woman and her miseries, of the many conditions inducing and perpetuating the uterine syndrome, of the relation of uterine deviations to other lesions, and the necessity for selecting skilfully a proper operation, with other treatment added, which shall not only comfortably and permanently replace the organ, but relieve the woman of coexisting pathologic states.

55. **Eclampsia.**—The four cases presented by Kosmak are examples of the average run of eclamptic cases, except that two of them were especially severe. Notwithstanding this, the amount of albumin in the urine was not very great, although the quantity of the urine was restricted. It seems to Kosmak that the latter is a fairly safe guide in the prognosis. Emptying the uterus should, he says, constitute only one step of the treatment and should be carried out with the least possible danger to the mother. This means that the forcible methods of dilating the cervix which have been so largely employed in this class of cases should not be permitted, as we have other means to accomplish the same ends. Vaginal Cesarean section or that by the abdominal route, if no contra-indications are present, offers an excellent chance for rapidly relieving the uterus of its contents. There is no doubt whatever but that the former operation can be carried out rapidly and satisfactorily as regards the actual delivery of the child, but the suture of the wound in the cervix and also in the lower uterine segment is necessarily a difficult procedure as it is almost impossible in many cases to bring the upper portion of the wound down into the field of vision.

58. **Abstraction of Calcium Salts.**—Drennan is convinced that the abstraction of calcium salts from the mother by the fetus causes fatty infiltration of the liver cells of the former. This fatty infiltration causes disturbed liver function with the production of toxins from imperfect protein digestion. Circulation of toxins causes fatty degeneration of liver cells thereby increasing the inability of the liver to functionate, with resulting increased toxemia. She says that no chloroform should be administered as it produces fatty degeneration of liver cells. The prevention and treatment of this condition consists in a liberal calcium diet, lessened protein food and, if the patient is not seen until labor has commenced, rapid delivery to rid her of the fetus which is draining her of calcium salts. The hemorrhage attendant on delivery—and in these cases it is sometimes excessive, owing, no doubt, to lack of calcium salts in the blood—will rid the organism of much toxic substances and have a curative effect.

65. **Commitment of the Insane in California.**—The evils connected with the apprehension, detention and commitment of the alleged insane, and their transfer to state institutions are summed up by Hoisholt as follows: (1) They, as sick people, are not understandingly looked after by the police or constables at the time of their arrest. (2) They are still, in some quarters, kept in insanitary places of detention (jails), in which they are given little if any medical attention, and which places are now and then infested with vermin. They are not kept clean while there, nor as a rule furnished with clean clothes when they leave. (3) They are not given as thorough an examination prior to and at the time of their commitment in court as many of the cases require, the special qualifications of the examiners in lunacy being much below par, a matter, however, which time and proper teaching of psychiatry in the medical schools can rectify. (4) They are escorted by men who are accustomed to take care of criminals, but unqualified as nurses to look after this particular class of sick people, and who are doing this in a very uneconomical way.

69. **The Making of a Health Officer.**—Rucker suggests that if a state is blessed with an unusually efficient and progressive board of health, what would be more natural than for that board to offer instruction gratis to all health officers within the state? The cost would not be great and would include printing, postage and a few books of reference to be loaned to those taking the work. As an experiment, a course in public water-supplies might first be offered, and if this proved a success, the scope of the work might be extended. It is believed that such an opportunity would be welcomed, and in offering it no reflections would be cast on the ability of those who, against great odds and an insufficient remuneration, are fighting the public's sanitary battles. A few lectures on hygiene and the occasional opportunities for self improvement afforded by the meetings of the health officers' association and a few scattering articles in the medical journals, cannot be compared with a regular course of study mapped out by men of the experience and learning of an efficient state board. It is admitted that the correspondence method of instruction is not ideal, but it is believed that it would serve to close the present hiatus until better means can be afforded.

83 *The Open-Air Treatment of Postoperative Nausea and Vomiting from Chloroform and Ether. F. L. Barnes, Trinity.

83. **Open-Air Treatment of Nausea.**—Barnes believes that the very best treatment for chloroform and ether nausea and vomiting is plenty of fresh air; that it is not only essential that fresh air should be supplied in a large volume, but that it should be kept moving, in order that the nauseating odors of the exhalations may be removed rapidly. His observation has this history: A great many negroes for whom there are no hospital accommodations, come to his associate and himself for operations. Originally they had an operating room and beds in connection with their office, but it soon became such a nuisance to have this class of patients continually around the office that they hit on the expedient of having them carried immediately from the operating room to their boarding places. Out of a great many cases handled in this manner, they have never had a single mishap, or a single bad symptom follow the practice. They have never known one of these patients to vomit after being carried into the open air, and they are almost never nauseated. The distances from the operating room to the places to which these patients have been conveyed have varied from ¼ of a mile to 2½ miles.

Immediately on the completion of the operation, the patient is placed on a cot, wrapped in blankets, with the face always exposed to the open air, and external heat applied. The cot is then placed in a wagon or hack and driven slowly to the boarding place. If the patient is awake and nauseated when the hack arrives at its destination, they direct that the cot be not carried into the house until the nausea passes off; they also direct that as few attendants as possible be about the patient. They have frequently observed that when they have been a little slow in getting patients out of the operating room, and the latter become nauseated as a result, they will immediately become quiet and drop into a peaceful sleep as soon as they are carried into the open air and started on their journey. It is the practice of the authors to prepare patients for operation by giving a large dose of castor oil or Epsom salts the night before, and an enema of warm salt solution on the morning of the operation; they also generally administer a hypodermic of morphin, ¼ grain, and atropin 1/150 grain, one hour and a half before the operation. A very light supper of soup or broth is allowed the night before, but no breakfast on the morning of the operation.

104 *A Safe Guide for the Administration of Tuberculin. O. H. Benker, St. Louis.

100. **Treatment of Malaria.**—Speaking of the use of quinin in malaria, Meara says that there is no question that this drug were better given in solution and, indeed, when the condition of the stomach leads to a suspicion of impairment of function and hydrochloric acid may not be secreted, the solution should be used. The drug is freely soluble in any dilute acid, hydrochloric, sulphuric, phosphoric or tartaric. A minim to the grain is enough. The objection to this method is the intensely bitter taste. Effort may be made to disguise it. One way is to dissolve the dose in a few grains of citric acid (gr. x), in a little lemon juice, add to it water in which a pinch of bicarbonate of soda has been dissolved and take while effervescing. In the tertian or quartan fever of a non-pernicious type, Meara says, the daily dose of quinin to begin with should be gr. xv to gr. xx. In the estivo-autumnal form gr. xxx. In the first mentioned forms, Meara prefers to give, if the patient is seen before the paroxysm, gr. xv of quinin sulphate; if seen during the decline of the fever, the same dose. From

that time on he gives gr. xx, divided into four doses in the twenty-four hours (the dose at the decline of the fever forming a part of it), until the succeeding paroxysm is aborted, then diminishing the dose gr. ii every two days until the dose is reduced to gr. vi a day, for three or four weeks. In the estivo-autumnal forms, he gives the large dose gr. xxx to begin with, and after aborting the paroxysms, reduces to gr. xx or gr. xvii and proceeds in the same way as above. In the pernicious infections, quinin must be used hypodermically or intravenously according to the urgency.

The best salt for hypodermic use, in Meara's opinion, is the acid hydrochlorate, which dissolves in less than its own weight in water. He makes up a solution as follows:

℞	gm. or c.c.		
Hydrochlorate of quinin............	5	or	gr. lxxv
Distilled water	10		℥ijss

Use 15 minims as a dose, which will contain 7½ gr. of quinin.

The amount needed in the twenty-four hours is about 24 grains, given in divided doses in this way. In the severe but less urgent forms, if given by the mouth, the amount should run up to 30 or 40 grains a day. In most urgent cases, it may be deemed advisable to put the drug into a vein. This may be done in physiologic salt solution. For example:

℞	gm. or c.c.		
Hydrochlorate of quinin............	1		gr. xv
Sodium chlorid	0|075	or	gr. i
Water	10		℥ijss

Inject all at once into the basilic vein made prominent by a ligature above. Other veins, if more accessible, may be chosen.

102. **Lobar Pneumonia.**—Briefly, the cases reported by Stockton are: (1) Typical lobar pneumonia; marked leucopenia without grave depression; rise of blood-count with defervescence; (2) typical lobar pneumonia and convalescence; three weeks later the patient returned with hyperemia of the lung, fever and serious pharyngitis; abscess, pure pneumococcus culture; (3) pneumonia; acute arthritis; pneumococcus and staphylococcus recovered from blood, staphylococcus vaccine, recovery; (4) chronic valvular disease of the heart, lost compensation, acute arthritis, lobar pneumonia, septicemia, septic endocarditis, pericarditis, hemiplegia; (5) alcoholic, pneumonia, slight involvement, delirium, severe trauma, acute, general pulmonary edema; (6) sudden invasion, high temperature, pulse and respiration, thoracic pain, termination by crisis, physical signs of localized edema.

104. **Tuberculin Administration.**—Benker endorses the method which was advocated and used for a number of years by Sahli.

110. **The Catalytic Activity of the Blood.**—In his studies of the catalytic activity of the blood in disease, Winternitz followed fifteen cases of typhoid throughout the illness. During the early days of the illness there was no change in the catalytic activity of the blood, but toward the third week there was a gradual fall accompanying the anemia. During convalescence the activity became normal together with the red blood-count. Twelve cases of diseases of the respiratory tract, including lobar pneumonia, tuberculosis and empyema were examined. There was a slight decline in the catalytic activity of the blood during the course of lobar pneumonia. The relation of this decline to the crisis and the salt metabolism of this disease has not yet been determined by Winternitz. In other diseases of the respiratory tract there was no noteworthy variation in the power of the blood to split hydrogen peroxid, except when the disease was accompanied by a severe anemia. In four out of five cases of acute peritonitis examined, there was a characteristic rise in the catalytic activity of the blood. In one a reading had been made before the peritonitis had occurred, while in the other three the increased activity was confirmed by the decline to normal, following operation. In two cases of suspected peritonitis with high fever and leukocytosis, the catalytic activity of the blood was normal, and in these cases the peritoneum was found clean at operation. Diabetes mellitus and catarrhal jaundice exerted no influence on the catalytic activity of the blood. In diseases of the thyroid, both hypothyreosis and hyperthyreosis, the catalytic activity of a single patient's blood was not constant from day to day. In hyperthyreosis the activity tended to increase, while in hypothyreosis the activity assumed a level lower than normal. Winternitz suggests that this may be of significance in interpreting the condition of the thyroid where the signs and symptoms are atypical. In renal, cardiac and cardiorenal cases (twenty-four cases were examined), despite the presence of a marked nephritis, provided there were no symptoms of renal insufficiency (uremia), there was no marked change in the catalytic activity of the blood. In cases of chronic nephritis, accompanied by indefinite symptoms of renal insufficiency the catalytic activity of the blood was irregular from day to day, and tended to assume a level lower than normal. In acute mercurial nephritis there was a fall in the catalytic activity of the blood. With uremic coma there was a marked fall in the catalytic activity of the blood which was permanent if the coma ended fatally, but which recovered when the coma disappeared.

With retention of urine due to obstruction of the lower urinary tract, there was a marked decline in the catalytic activity of the blood. This decline, Winternitz says, may persist for some time, but should the obstruction be removed, the catalase will again rise. Even in severe cardiac disease there is no significant change in the catalytic activity of the blood. In some cases it is high. This may be normal for these individuals, as it will be remembered some individuals have a high activity. In no single case was the activity sufficiently decreased after many readings had been made to suggest renal insufficiency. In three cases of cardiorenal disease, in which the clinical findings suggested a renal insufficiency, the catalytic activity of the blood was normal. At autopsy only a chronic passive congestion of the kidneys, the result of a decompensated heart, was found. In two cases of cerebral hemorrhage the catalytic activity of the blood was high. Whether this is an increase over normal is not known, but it is clear that the high reading would differentiate apoplectic coma from uremic coma.

112. **Blood Platelets in Hodgkin's Disease.**—The findings presented by Bunting would seem to indicate that in Hodgkin's disease there is a special activity of the platelet-producing elements resulting in the production of large numbers of platelets and in the emigration of megalokaryocytes in large numbers from the bone marrow. In the lung capillaries these latter are stripped of their protoplasm, which appears in the peripheral blood-stream in the form of the masses and pseudopodia described. What part this increased platelet production plays in the disease, Bunting is unable to say. There is in the findings a suggestion that the toxin of the disease acts as sharply on the megalokaryocytes as on the lymphoid elements, leading eventually to their necrosis.

115. **Growth of Embryonic Chick Tissues.**—Very wonderful growths from the various organs of embryo chicks of various ages have been obtained by the Lewises. The blood of adult

chickens was used. Not only were growths obtained in hanging drops, but much more extensive ones were obtained in Petri dishes, the diameter of these growths sometimes exceeding one centimeter. There was great similarity in the growths from pieces of liver, intestine, heart, brain, kidney, adrenal, muscle, stomach, thyroid, retina, cornea, etc., of chick embryos from 10 to 21 days old. Radiating strands, migrating cells, membrane formations and vesicles or loop-like places seem to be common to all. The spleen, however, usually sends off migrating cells alone for some time after the culture is made, and only later do the radiating cells appear, if they appear at all. The general similarity of the growths from the various organs leads the authors to the conclusion that the growing tissues are only such as are common to the various organs, namely, connective tissues of various kinds and endothelium of the blood-vessels. They have been able to trace, in some fixed and stained specimens, the endothelium from the blood-vessels of the original piece out into the new growth where the cells of the endothelial radiations closely resemble the cells of the other radiations found there. Recently, they succeeded in cultivating small pieces of embryonic chicks in a nutrient agar both in hanging drops and Petri dishes. The growths have, as a rule, not been so extensive as those in the plasma, but otherwise resemble them. Some specimens show radiations, others membranes and reticular formations with migration of cells. Mitotic figures are found in the stained preparations. The cells often show long irregular processes and move outward from the old piece. The following medium (Ringer) has so far given the best result with chick tissue:

Sodium chlorid	.9	10 c.c.
Potassium chlorid	.042	
Calcium chlorid	.025	
Sodium bicarbonate	.02	
Water	100.	
Agar	.25	
Bouillon		2 c.c.
Sodium chlorid		.0675 gm.

Into a hanging drop of this medium they transplanted two small pieces from the liver of a 9-day chick embryo. Within twenty-four hours cells began to radiate and migrate from the smaller piece into the surrounding medium. In forty-eight hours the growth had exceeded that of the control in plasma and was as extensive as any growth observed in plasma from such a small piece, less than 0.5 mm. in diameter. The entire growth at the end of forty-eight hours was four times the diameter of the original piece and could readily be seen with the unaided eye.

125 Adenoids. C. B. Wylie, Chattanooga.

122. **Ascites.**—Twenty-one years ago, Beasley's patient, a miner, was kicked by a mule in the right side, over the liver. This gave trouble for some time. Afterward his abdomen began to enlarge, but never gave him any great amount of trouble until January, 1909, when he was unable to go into the mines for six or eight weeks. In August, he was considerably emaciated, complained of some pain over the liver, though no tenderness on pressure. The abdomen was so distended that it was impossible to tell whether the liver was enlarged or not. Diagnosis was ascites caused by cirrhosis of the liver. Beasley gave various hydragogue cathartics and diuretics without any effect. Repeated attempts to aspirate proved futile. Finally operation was advised. On opening the abdomen, the incision filled up with a cheesy mass which soon passed out. After this ½ gallon or more of fluid of an amber color escaped. The incision was then enlarged, when cysts of various sizes from a small marble to a croquet ball, together with a large number of collapsed cysts, began to roll out. It was necessary to rupture a great many of the cysts in order to remove them. The abdominal cavity was completely filled with these cysts. Some of those that were collapsed showed that it had been some time since they ruptured. These cysts had no attachment to anything, but were packed in the abdominal cavity until there appeared no room for more. The small intestines were pressed up against the diaphragm. The peritoneum and all the abdominal organs had a yellow anemic appearance. Their walls were considerably thickened, and had a rough granular feel. The patient died thirty-six hours after operation. Beasley's final diagnosis is echinococcus cysts of the peritoneal cavity.

134 *Functional Periodicity in Women and Some of the Modifying Factors. C. Mosher, Palo Alto, Cal.

134. **Functional Periodicity in Women.**—Mosher defines menstruation as a periodic flow of blood from the uterus of a woman, occurring at fairly definite intervals (reckoned from the first day of the onset of the flow to the first day of the next onset) in the same individual, but the intervals varying in different individuals, this function being unattended with pain or incapacity due to it as such. Mosher says that if we can divorce our minds from all preconceived notions in regard to this function, be they derived from individual experience, sex tradition or accepted teachings, and consider it as we do the other periodic functions, this definition will not seem unreasonable. In the first place, she continues, it must be admitted that there is no reason for treating this function differently from the other periodic functions, such as sleep, digestion, defecation and urination, which likewise have their departures from the normal. In the second place, the observers of menstrual disturbances do not by any means agree as to the numbers affected or the degree of the infirmity. Moreover, the various bodies of statistics giving the percentage of women suffering at the menstrual period have all been based on single statements from women examined. Mosher is convinced that many of the so-called dysmenorrheas are not dysmenorrheas at all, but coincident functional disturbances in other organs. It is highly suggestive that the symptoms coincident with low blood-pressure usually are slight, in busy, active women, as in men. When the attention is of necessity directed to so obvious a process as the menstrual flow, untrained women,

especially if without absorbing occupation, naturally refer their lessened sense of well-being and diminished sense of efficiency, which may accompany the lowered general blood-pressure occurring near or at the menstrual flow, to the function of menstruation.

In a group of average women, Mosher has produced a marked improvement at the menstrual period by using so simple a measure as deep breathing. All constricting dress having been removed, the women, in the recumbent position and with knees flexed to relax the abdominal muscles, have done deep breathing once or twice a day during the menstrual period, with the result that all pelvic sensations, depressions and minor symptoms usually included in the term dysmenorrhea have disappeared. In a number of cases also the period has been shortened more nearly to conform to the period of principal flow. These experiments, Mosher thinks, tend to emphasize still further that the upright position, the force of gravitation and constricting dress are conjoined factors in hindering the circulation of the blood from the pelvis to the heart, and are therefore important factors also in producing dysmenorrhea. Since in women of the uncivilized races we find the minimum of flow with no disability and perfect functioning, there can be no danger in gradually lessening by such physiologic methods the period of prolonged pelvic congestion.

145. Detection of a Case of Simulation of Insanity.—In the case reported by Katzen-Ellenbogen, the association test proved very satisfactory. In his general discussion of the subject the author points out that psychology, even in its present adolescent state, can be of assistance in problems of practical life, although it would be entirely wrong to contend that by the association test the truth of a person's statement could be positively determined. Indeed, if the association test were to be used for this purpose, he should prefer to refrain from the use of it altogether. He believes, however, that by skilful application to certain cases, the association test may prove a very valuable addition to many tests in criminal investigating work, as has been lately shown by the Bertillon methods, etc., and be of great assistance in many instances for clearing away doubts as to the truthfulness of witnesses.

In the case under review Katzen-Ellenbogen worked with a man wholly unprepared and incapable of understanding the purpose of the investigation, ignoring the facts that a hesitation, the change of word in the reproduction, were the very instances which would most convincingly tell against him. Considering even the circumstance of his knowing these facts, of his even being a psychologist quite skilful in psychologic technic, he would be equally unable to control the form of his answers and the time of associations, even to a fraction of a second. The attempt to control his answers or prepare them beforehand would incriminate him more than anything else. In this same way a refusal to cooperate might be equally harmful as a result. This argument in favor of the association test is rather directed to the sceptical students of law, as the psychologists themselves are more inclined toward an optimistic than a pessimistic view of the success of these tests. The criminal himself would hardly object to this form of investigation, as it would rather impress him with the fact of his having been cleverly overtricked; to the very end both he and the examiner are able to remain on friendly terms, as it happened in the case reviewed.

3. Dilatation of the Stomach.—Nearly all the recorded cases of acute dilatation are alike in obscurity of cause and fatality of termination. Farquhar cites a case in which one cause was not only clear, but removable, and the result was uninterrupted recovery. A young woman, aged 23, was advised by a "wise woman" to eat figs in order to burst a small abscess in the axilla. She ate nearly a pound of dried Turkey figs at 11 a. m., Dec. 24, 1910. Two hours later, ineffectual retching set in with abdominal pain, which continued with increasing severity all day and the following night. The bowels moved slightly in the evening. The girl had several alarming attacks of breathlessness in the night. Farquhar was summoned at 9 a. m. the next day. The abdomen was not distended, and moved slightly with respiration. There was a general slight increase of resistance and a diffuse tenderness, most noticeable between the umbilicus and the left anterior superior spine. The pain had come on gradually and was now severe, especially in the epigastrium, but also in the left iliac region. The pulse was 84 and the temperature normal. After examination she sat up with a sudden cry and gasped for breath; the pupils dilated fully, and showed momentarily a slight red reflex. For about ten minutes she looked as if she might fall back dead. When she regained her breath, a little brandy and water was given and she began to retch, but only a little fig pulp came up. As this seemed too thick to flow through a stomach tube, none was passed lest it should provoke another attack of dyspnea. One hour later, a slightly distended dull area could be made out below and to the left of the umbilicus. An enema of soap and water was ordered and hot applications to relieve the pain, but no morphin was given at this stage.

Twenty-nine hours after the onset of pain and vomiting, the abdomen was opened. A large swelling like an ovarian cyst presented in the wound. It was tympanitic above but dull below, and was found to fill the whole of the front of the abdomen. It was recognized as an enormously distended stomach, the greater curvature being hidden below the pubis, and the lesser curvature appearing like a vertical chink between the inflated halves of the organ. The dilatation seemed to extend to the second stage of the duodenum. An area of the stomach was drawn forward and packed off with gauze from the peritoneal cavity. A small incision was made to allow gas to escape. Fluid containing fig juice and emitting a strong vinous odor, flowed freely for a time, and then masses of half-masticated figs were removed with a scoop. The pylorus and the first part of the duodenum were found to be dilated sufficiently to admit three fingers. When all the contents had been removed, the stomach contracted gradually till the greater curvature was just below the umbilicus. The wound in the stomach was closed in three layers, and the abdominal wall brought together in the usual way without drainage. Recovery was uneventful and complete.

4. **Treatment of Appendiceal Abscess.**—The striking inhibitive effects of phenol when used for external conditions led Maylard to venture on its employment in cases of appendiceal abscess in which the extreme offensiveness of the discharge and the necrotic processes in the appendix suggest conditions not altogether unlike those met with in traumatic gangrene. The abscess cavity is freely wiped with a small gauze swab soaked in pure phenol. An effort is made to reach every part of the cavity. A dry swab is then introduced to soak up any of the remaining acid, and immediately thereafter any amount, up to a half a teaspoonful, of iodoform is put into the cavity, and with a blunt instrument smeared over its walls. A rubber drainage tube about a quarter of an inch in diameter is conducted to the lowest part of the cavity, and on one side of the tube a narrow strip of iodoform gauze is packed in zigzag fashion, just sufficient to fill the cavity; this, with the tube, is conducted out of the abdomen about the center of the wound. The after-treatment is as follows: On the second day after the operation, the iodoform gauze packing is partially removed; on the third day it is completely removed; and, however fetid may have been the pus at the time of operating, the plug will be found to be perfectly "sweet." On the fifth or sixth day the drainage tube is taken away, and on the tenth day the stitches are removed. At the end of four weeks the patient is allowed up.

In sixteen out of the twenty-seven cases cited by Maylard, the abscess was reached by the ordinary "gridiron" incision, neither muscle nor aponeurosis being divided across the direction of the fibers. In twenty-five cases out of the twenty-seven, the appendix was sought for and removed. In one of the remaining two it was only partially removed, as a portion had disappeared, while in the other it could not be found. Every patient recovered, and in none were there any subsequent complications, such as subdiaphragmatic abscess, pylephlebitis, pneumonia or other conditions suggestive of septic absorption or local accumulations of pus. The pulse and temperature usually fell within twenty-four hours. The subsequent results of operation were traced in twenty-five out of the twenty-seven cases, and nineteen of these twenty-five patients were seen and examined. With the exception of the twenty-seventh patient, who had only been operated on a month previously, the interval between operation and report ranged from three months to four and three-quarter years. An examination of these results shows: 1. When the "gridiron" incision was employed, in ten out of fourteen cases there was some bulging of the cicatrix, mostly slight and in almost every instance at the place where the drainage tube and gauze packing emerged. 2. When the internal oblique and transversalis muscles were cut across by extending the incision upward, three out of six cases showed bulging, the protrusion being in one case at the seat of exit of the drainage tube, and in the other two at the lower part of the cicatrix. 3. When the internal oblique and transversalis muscles were cut across by extending the incision downward and inward, the three cases so treated showed bulging. Maylard is convinced that, when proper precautions are taken to protect the general peritoneal cavity, this method of operating admits of every abscess being opened and every appendix sought for and removed with perfect safety. This method prevents any subsequent septic complications, such as subdiaphragmatic abscess, pylephlebitis, pneumonia, thrombosis and other septic manifestations connected either with the wound locally or with deeper and more distant parts. As drainage is considered advisable in every instance, the probabilities are in favor of a weakened cicatrix at the seat of exit of the tube and gauze, with, later, hernial protrusion; but, provided the incision is of the "gridiron" variety, with no cross division of muscle or aponeurotic fibers, and neither the tube too large nor the packing excessive, the bulging may be only slight.

6. A similar article by these authors was abstracted in The Journal, Sept. 10, 1910, p. 973.

7. **Asiatic Cholera.**—Of 326 cases of cholera occurring in the Funchal epidemic treated in the Isolation Hospital, Funchal, Madeira, in roughly 75 per cent. there was an acute onset; in many it was fulminating. In the remaining 25 per cent. the onset was gradual. The duration of symptoms in those individuals who recovered was from three to ten days. In only 5 per cent. of the cases were cramps in the legs and abdomen absent. After acute symptoms had passed off, about 3 per cent of the patients went into a condition resembling typhoid, with tympanites, slight secondary diarrhea, headache and temperature above 101 F. for more than a week. Some of these gave the Widal reaction in the stronger dilutions, but they all recovered within a fortnight. About 10 per cent. of the patients were chronic alcoholics, and this class of the community seemed especially prone to take the disease. Of the female patients fully 10 per cent. were lactating, which seems a high percentage. There were also five pregnant women among the patients. Of these, four aborted, two between the second and third month and two between the sixth and seventh month; two died, but without any puerperal complications. Among the 326 patients, there were thirty infants under 3 years of age and forty-two persons over 60. The epidemic, comprising about 1.700 cases for the whole island of Madeira, has been disseminated entirely by food and actual contact, and not by means of water supply. It was stamped out by rigid isolation or segregation of all "contacts." Systematic examination of the feces was carried out in the case of all convalescents, all inmates of the "contacts" segregation block, and all hospital employees. Of the 206 convalescents, twenty carried the vibrio in the feces for more than a fortnight after the disappearance of the active symptoms. Out of about 350 inmates of the "contacts" block, only six actually developed the disease, but many who never showed symptoms were found to carry the vibrio in the feces for more than three weeks after being in contact with a patient

11. **Diagnosis of Gall-Stones.**—Of forty-three patients suffering from gall-stones and operated on by Sherren during the past two years, twenty-six had had indigestion, for which they had been under medical care for long periods; one patient after being treated for gastric ulcer was sent to the hospital on the occurrence of her first attack of colic as a case of perforated gastric ulcer. Another patient had had gastro-enterostomy performed without relief; at operation, Sherren removed 140 small stones from the gall-bladder and one from the common bile-duct. Of these twenty-six patients, twenty had had attacks of biliary colic after periods of indigestion ranging from five months to forty years; in the majority of the cases the history of indigestion was of over five years' duration. The special points in the dyspepsia due to biliary calculi Sherren believes are these: its association with flatulent distention; the frequency with which the patient is awakened at night; the pain is not relieved by taking food, and if associated with vomiting this may not relieve it, but vomiting is unusual. Abdominal examination in these cases may settle the diagnosis; for example, in two of the cases in which Sherren operated, before the onset of colic a distended gall-bladder was distinctly palpable. Tenderness under the right lower ribs is usually present and Murphy's sign may be elicited. Occasionally no physical signs exist. A large proportion of all cases of duodenal ulcer give symptoms enabling a certain diagnosis to be made, the most important being hunger pain relieved by taking food and waking the patient in the early hours of the morning. In these cases the ulcer is in the first part of the duodenum. These symptoms are never produced by gall-stones. There are cases, however, in which the symptoms of gall-stones are mimicked closely by those due to an ulcer in the second part of the duodenum. Cases of this nature are, however, unusual. Among the forty-six cases of chronic duodenal ulcer that Sherren has operated on before perforation has taken place, the symptoms in three simulated those due to gall-stones, and in these the ulcers were situated in the second portion of the duodenum.

13. **Enlargement of Thyroid.**—Hutt calls attention to the fact that slight general enlargement of the thyroid is fairly common in some districts. The number of cases investigated, unfortunately, does not warrant any very definite conclusions.

16. **Inhibition of Tumor Growths.**—On the assumption that some kind of protective substance might be formed in animals affected with epithelioma, the authors injected the serum of a mare having epithelioma of the vulva into some cases of cancer, more especially one of uterine cancer. A violent reaction followed each injection (which was made locally), and the case was modified from an inoperable to an operable condition. Both operation and further treatment were refused, and when the patient returned later, renewed treatment with the serum from another mare failed to reproduce the former effect. Later experiments showed that in rats, regression of inoculated growths may follow the injection of epitheliomatous horse serum and also of simple horse serum, and that this regression occurs in the greater proportion of treated than of untreated rats. Another quite different series of experiments revealed the curious and interesting fact that it was not possible simultaneously to produce immunity against cobra venom and to retain susceptibility to new growth inoculation in mice and rats, nor, conversely, after successful inoculation with tumor, to produce immunity to cobra venom. If the tumor were already present, and continued to enlarge, the animal succumbed to a few ordinarily sublethal doses of cobra venom. On the other hand, in those animals in which immunity could be established, growths which had already reached a size of 1 cm. in diameter would regress.

The inference from this series of experiments was that if the treatment caused the regression, such regression must be due to some antibody or antibodies formed as the result of this active immunization. If this were so, passive immunization with antivenom serum should produce similar effects. Therefore, a series of animals with well-grown tumors was treated with antivenom serum. Regression took place only when the growths had not exceeded about 1.5 cm. in diameter. The authors feel that the results of these experiments warrant the extension of the treatment to human beings, and at the same time show that quite inoperable cases are not fair subjects for such trial, for it seems not unlikely that similar limitation to that seen in rats will exist in the case of man. Three human patients have already received treatment by combined passive and active immunization, but since the mass of tumor was large in each case and was not excised, they were not fair cases for the purpose, although they showed that the treatment in itself was harmless. It is not possible to state whether any lasting effect was produced on the growths, since the patients left the hospital too soon for the formation of a definite opinion.

29 *Pneumonia Due to a Gram-Negative Diplococcus. A. S. Vallack.
30 Biologic Properties of the Cholera Vibrio and Other Vibriones. B. Bradley.

29. **Pneumonia Due to a Gram-Negative Diplococcus.**—About thirty cases of pneumonia due to this coccus have come under Vallack's notice, and the features of the disease have been so characteristic that there is little difficulty in differentiating it from pneumococcus pneumonia. In cases of pneumonia due to the pneumococcus, as a rule, only one member of the household is attacked. In the case of pneumonia due to the Gram-negative coccus, other members of the household are attacked by the same germ. The onset of ordinary pneumonia occurs with the greatest suddenness. With the other coccus the onset is not sudden; the patient is ill for several days with catarrh of the upper respiratory tract before the pneumonia supervenes. The temperature of ordinary acute pneumonia is perhaps more characteristic than that of any other disease. In the other disease the rise is more gradual, reaching high-water mark about the third day. The fall is by lysis, and it may take from two to six days or more to accomplish. The toxins of this germ are not nearly so depressing to the heart as those of the pneumococcus. A fair amount of pain may be present, but Vallack has not seen in any case the agonizing pain which may be present in pneumococcus pneumonia. A remarkable difference in the two affections is seen in the comparative absence of distress in this disease. A patient with one whole base consolidated will lie in bed with comparative comfort. The sputum is much more scanty as a rule than in the pneumococcus disease, and may be entirely absent even when considerable consolidation is present. When present it

is of a rusty color and contains numbers of encapsulated diplococci. These are often in large groups comprising fifty or more. They are decolorized by Gram's method. The physical signs of a fully developed case are similar to those of ordinary pneumonia. The stage of suppressed breath-sounds, however, which is common to both diseases, often lasts a good deal longer in this disease than in that due to the pneumococcus. One may find places where the breathing is still suppressed several days after the onset of the disease, while in other places tubular breathing is present. The disease is much less fatal than pneumococcus pneumonia, chiefly owing to the effects of the latter on the heart. Vallack emphasizes that this disease is infectious, and patients should not be admitted to the wards with other patients. Occasionally a patch of this pneumonia takes some time to clear up, giving rise to a suspicion of tuberculosis.

48 Three Cases of Peroneal Paralysis. W. B. Jack.

40. **Low Blood-Pressure.**—Individuals presenting low blood-pressure, Edgecombe says, are subjects with poor circulation, cold hands and feet, and liable to chilblains. He has encountered several examples in which the systolic blood-pressure rarely rose above 95 mm. Hg. By means of baths, massage and exercise, a temporary rise may be effected, during the maintenance of which the objective and subjective signs of defective circulation improve manifestly; but it is difficult to effect an enduring rise in the general level of blood-pressure in these cases, for they are prone, on cessation of treatment, to relapse to their former state. In cases of pure neurasthenia, having as their prominent characteristic, profound fatigue either somatic or psychical, or both, the blood-pressure is also low. A woman had a systolic pressure of only 85 mm. sitting, and 80 recumbent; she was subject to most violent headaches and had been dosed freely and for long periods with the usual headache remedies. A rise in tension of the circulation temporarily afforded relief to the pain. Whether the low blood-pressure in these cases of neurasthenia is the cause or the effect of the extreme fatigue, Edgecombe says is not easy to say. The probable sequence of events is a lowering of blood-pressure by toxic or other causes, and it is the extreme feebleness of the circulation that gives rise to the subjective sensation of intense fatigue. Certain it is that a rise in blood-pressure is an almost invariable accompaniment of improvement. In marked contrast to these is the irritable type of neurasthenic—the "neurotic" individual, who is frequently not a true neurasthenic, but a psychasthenic or a hypochondriac. In these cases the pulse is usually quick and irritable, and the blood-pressure subject to great variation, but generally above the normal and sometimes markedly so. Tobacco raises the blood-pressure and yet heavy smokers frequently have subnormal pressure. In cases of dilated heart, with or without valvular disease, the pressure will sometimes be found low, and a rise in pressure is one of the indications of the progress of the case toward recovery. Edgecombe has seen many examples of the so-called gouty or rheumatic manifestations—lumbago, sciatica, neuritis—which showed a blood-pressure somewhat below normal. Many of these patients have a subnormal acidity of the urine, and are liable almost constantly to a copious deposit of phosphates; and this leads to, or is accompanied by, a state of nervous depression, which is a very real thing to those who suffer from it. The origin of the diminished acidity is digestive, and the nervous depression is due to reflex disturbance from irritation of the sensitive nerve mechanism of the bladder and urethra by the phosphatic urine. It is remarkable how rapidly the blood-pressure will rise and the symptoms disappear if the urine is rendered acid and the phosphates kept in solution. The clinical symptom phosphaturia, in whatever condition it may occur, is usually accompanied by a low blood-pressure, probably for the reason given above. Subacute cases of rheumatoid arthritis in young subjects frequently have a blood-pressure below normal, which rises as the condition improves. Exercise, carefully graduated, improves the tone of the heart and vessels and raises the pressure, while altitude and baths have a marked effect in the same direction.

Annales des Maladies des Org. Génito-Urinaires, Paris

March, XXIX, No. 5, pp. 385-480

49 *Polycystic Disease of the Kidney. (Les reins polykystiques.) Pousson.
50 Segregation of the Urine in the Female Bladder. (Un instrument qui rend exacte l'application du séparateur de Luys chez la femme.) D. Taddei.

49. **Polycystic Kidney.**—Pousson reports good results from operative treatment of polycystic degeneration of the kidney in three typical cases and fair results in forty-two others. The operations do not cure completely, he remarks, but they combat the accidents and complications which increase the gravity of the condition and threaten life. The indications for operation are compression of neighboring organs, pain, hematuria, uremia, oliguria, anuria or suppuration. Nephrotomy is the preferable operation. One patient, a carpenter, is in comparatively good health to-day after nephrotomy early in 1908; he had long suffered from gall-stones. The left kidney was in advanced cystic degeneration. During the three years since the nephrotomy the man has been free from all pain and has worked constantly. In another case, the nephrotomy was done for oliguria, headache, cramps and other symptoms of mild nephritis. Pousson ascribes the affection to some inflammatory process, possibly traceable to some acute infectious disease or alcohol or lead poisoning, the gouty tendency or malaria. The assumption of a causal inflammatory process harmonizes further with the clinical course of the polycystic affection. Nephrectomy should be reserved for the tuberculous cases.

51 *Cancer of the Kidney in Two Little Girls. R. Buccheri.
52 Favorable Significance for Prognosis of Early Meteorism After Trauma of the Abdomen. D. G. Zesas.
53 *Sigmoiditis and Infection of the Internal Genitalia in Women. J. Poulain. Commenced in No. 1.

51. **Cancer of the Kidney.**—The cancers were a sarcoma and an epithelioma, both inoperable; the patients were 2 years and 7 months and 3 years old respectively. There was no history of traumatism, and the children were otherwise apparently normal.

53. **Sigmoiditis and Infection of Internal Genitalia in Women.**—Poulain warns that disease of the genital apparatus is very liable to spread to the sigmoid flexure. The microbes find their way by the peritoneum and induce production of adhesions which may cause serious trouble later. On the other hand, inflammation in the sigmoid region as a result of constipation may involve the genitalia and may cause misleading symptoms on the part of the ovaries or Fallopian tubes. These facts explain the predominance of left salpingitis. Whenever the adnexa are presenting symptoms of inflammation, the pains being most pronounced on the left side, he advocates hot intestinal enemas rather than vaginal injections, as, while they have practically the same therapeutic action, they permit

energetic disinfection of the sigmoid flexure. He insists that this should be done systematically before attempting to operate in case of salpingitis or for ovarian cyst, etc. These conclusions are based on nineteen cases, including six from his own experience reported in detail with summaries of the others.

65 Emotional Jaundice in Children. (L'ictere émotif chez l'enfant. Observation d'un cas suivi d'une petite épidémie familiale d'ictère infectieux.) P. Merklen.

59. **Infant Feeding.**—Comby emphasizes the importance of studying individual conditions, but his general rule is 100 gm. of good milk to the kilogram of weight when the infant is strong and well. This amount represents only 75 calories per kilogram, that is 34 calories per pound of weight, and this is not sufficient for weakly infants or the very young. These need 95 or even 100 calories per kilogram, which would require 120, 130 or 150 gm. of milk.

60. **Id.**—Gaujoux makes a point of analyzing the breast milk when a child is not thriving and states that a woman can increase the amount of milk from one-sixth to one-third by drinking fluids but the nourishing value of the milk is reduced in proportion. He warns further that infants fed artificially may not be getting the proper amount of nourishment as the mothers dilute the milk as directed, not realizing that the milkman has previously watered it.

63. **The Thymus and Glandular Disease in the Chest.**—Veau has removed the thymus in nine cases for disturbances in breathing for which the enlarged thymus was supposed to be responsible. But in two cases, notwithstanding the signs of thymic obstruction and difficulty in breathing and swallowing, attacks of suffocation and dulness over the manubrium, the thymus was found quite small. The whole trouble was an infected gland behind the sternum which Veau easily removed, the operation being followed by complete functional success. Removal of glands above the bifurcation of the trachea, behind the brachiocephalic vein, was very easy by this route which permitted also draining of the upper mediastinum. In these cases of supposed enlargement of the thymus an acute pulmonary affection had preceded the disturbances. In future, he says, he will look for mediastinal adenopathy instead of ascribing the subglottic stenosis exclusively to the thymus in such cases. Another sign that might have been instructive, if heeded, was that the difficulty in breathing seemed to be predominantly below the diaphragm; there was only a little above the clavicle and none above the sternum. The organs in the mediastinum were adherent from the preceding inflammation, so that there was no movement when the chest was opened. These adhesions explain the discordance between the diaphragmatic and cervical difficulty in breathing and this lack of agreement between them should suggest, Veau declares, infection of glands rather than enlargement of the thymus.

64. **Lavage of Abscesses.**—Ombrédanne gives an illustrated description of a puncture device connected with three jars and a bulb with which it is possible to aspirate the contents of an abscess, rinse it out and follow this with a disinfectant, all without changing the cannula. The apparatus can be used also for treating a suppurating gland in the neck; but for this he supplements it by drawing silk through the abscess to make an aseptic seton. The needle can be inserted in the silk and a quart of cleansing fluid sent through the lesion, followed by an iodin solution. The lesion is thus healed with merely two minute incisions, one above and one below.

69. **Growth of Tissue in Vitro.**—Carrel and Burrows here review their work in this line, which is already familiar to the readers of The Journal. Some of their most recent communications on the subject were published in The Journal, Jan. 7, 1911, and in the *Journal of Experimental Medicine*, March, 1911.

70. **Resection of Superficial Varices.**—Alglave summarizes his experience with total resection of superficial idiopathic varices in seventy-five cases. This operation restores working capacity and seems to be equally beneficial for the painful and complicated cases and for the less serious. The incision runs from ankle to groin, on the inner aspect of the leg, and the author advocates the operation in every case in which the varices begin to prove painful or annoying. There is no need to wait, he asserts, for subsidence of the phlebitis; but in this case he always ligates under local anesthesia the terminal segment of the internal saphena before operating on it, to avoid danger of embolism. In his cases the temperature dropped at once after resection of the inflamed veins, showing that the trouble was limited to the vein. In varicose ulcer, he resects a lozenge-shaped flap of skin with the segment of the vein, with Thiersch flaps in the rare cases in which there were no signs of healing after ten or twelve days.

75. **Nystagmus and Myoclonia.**—Lenoble and Aubineau give the details of thirty-eight additional cases of the peculiar myoclonia to which they called attention in 1905 as an affection comparatively common in western France and frequently of a familial type. The constancy and the fixity of the nystagmus render it the most striking of the group of symptoms. In the majority of cases the patients lead an active life with no other evidence of physical or mental degeneracy. The affection is congenital; in the few cases in which it was not noticed until after an intercurrent febrile affection, it had probably existed in a latent form. It belongs in the scale of myoclonias ranging from isolated nystagmus, through the nystagmus-myoclonia to Friedreich's paramyoclonus, Morvan's fibrillary chorea and Gilles de la Tourette's maladie des tics. All are manifestations of a special and obscure morbid condition resulting from a biologic degeneracy.

81 *Case of Winckel's Disease. F. Brandenberg.

76. **Acidity of the Urine in Infants.**—Lade discusses what is meant by "acidity" of the urine, the preferable technics for estimating it, the sources for the acidity and its causes, and the variations in acidity under diverse influences. He further reviews extensive clinical experiences and tests of various forms of infant feeding in respect to their influence on the acidity of the urine.

79. **Test Breakfast in Estimation of Stomach Functioning in Children.**—Seiler has applied Sahli's flour soup method (*Mehlsuppemethode*) to a number of children and has found it as instructive as in adults. The children like it, and he reports the findings in a number of healthy children and in others with various diseases, from a few months to 12 years and older. The details are given for forty-one children examined, including three with gastritis, five with secretory and five with motor anomalies. The findings are like those in corresponding conditions in adults, and exact differentiation is equally important for both children and adults, he declares, to permit proper treatment.

81. **Winckel's Disease.**—Brandenberg has been able to find in the literature about fifty cases of this disease. It is characterized by cyanosis, bloody urine, hemorrhage and icterus. Most of the cases appeared in epidemic form in Germany or Russia in new-born infants, only a few of whom survived. He reports a case personally observed, with necropsy. An infectious factor seems evident. Baginsky asserts that simple jaundice, acute fatty degeneration or Buhl's disease, and Winckel's disease are probably only varying degrees of the same process. The jaundice is evidently the result of the hemolysis.

88 Temperature Crises in Tabes Dorsalis. W. Stange and S. Brustein.

83. **Dangers of Salvarsan for Syphilitic Infants.**—Döblin gave salvarsan to six infants and reports that no benefit in the general condition of the child was observed in any instance, the children did not lose their pallor and did not increase in weight thereafter; one strong child died from salvarsan poisoning, although the dose was only 0.03 gm. In another case the infant gained 300 gm. in five days, which he regards as a sign of toxic action of the drug, like the herpes zoster sometimes observed in adults. Four of the infants died, including two in good condition before the injection; this was made subcutaneous or intramuscular in each case and there was little local reaction at the spot. The necropsy findings suggested, he reports, acute arsenic poisoning: acute paralysis of the central nervous system, coma, severe injury of the intestines with diarrhea, drop of the blood-pressure and total paralysis of the contractile elements of the mesenteric capillaries, the so-called splanchnic paralysis. The edema in the mesenteric and subcutaneous fat tissue was evidently the result of arsenic paralysis of the capillaries. The experiences related indicate, he thinks, that 0.03 gm. may be regarded as the fatal dose for infants under the age of 3 months. Even this amount does not ward off recurrence, and as improvement in the manifestations of the syphilis may be observed, as in one of his cases, even with so small an amount as 0.025 gm., it seems reasonable to accept for infants under 3 months from 0.01 to 0.02 gm. as the tolerated dosage, that is 0.005 per kilogram of body weight.

84. **Operative Treatment of Stomach Disease.**—Pochhammer comments on the constantly improving end-results of surgical treatment of non-malignant stomach affections, especially ulcers and their sequels, but adds that most surgeons now regard a cancer of the stomach as already inoperable when so advanced as to be diagnosed with certainty. He insists that while the ignorance and indolence of patients are largely responsible for the delay in seeking surgical aid, a not inconsiderable share of this responsibility should be laid at the door of the so-called stomach specialists. This, he declares, will have to be proclaimed openly and loudly. These stomach specialists are the ones to whom the victims of gastric affections apply, assuming that some special help may be obtained from them after the family physician, consulted in the first place, has come to the end of his resources. In fact it may be the family physician who advises consulting the stomach specialist. And then several weeks or months of possibly precious time are wasted with all kinds of examinations, tests, lavages and dietetic courses. A tumor is not yet positively palpable; the diagnosis of "chronic gastritis" has a tranquilizing effect at first until suddenly the tragedy begins anew and with increased violence as the symptoms show that the obstruction to the emptying of the stomach has increased, but the stomach rinsings may be continued even then for a short time. By this time, the patient is losing strength rapidly; then the case is regarded as ripe for operative measures; the apparently benign stenosis requires operative intervention, and this discloses carcinoma with extensive metastases. This history is taken from life, Pochhammer declares. It demonstrates the enormous responsibility that rests on the shoulders of the stomach specialists when they attempt to differentiate benign stomach affections which have been causing symptoms for some time from malignant growths. Surgeons, he adds, even when they hold the growth in their hands, may be unable to state positively whether it is benign or malignant. The only means of differentiation is by histologic examination, and the stomach specialists are least of all in a position to do this. He protests specifically against Boas' recent assertion that in practice the time need not be regarded as wasted when a stomach specialist applies symptomatic preliminary treatment to a gastric cancer before it is positively recognized as such. Boas bases this assertion on the premise that only the slowly developing gastric cancers are amenable to operative measures; those which develop rapidly are inevitably fatal, whether an operation is attempted or not. To this Pochhammer replies that while this assumption may tranquilize the stomach specialists it might have disastrous consequences if it were accepted generally by physicians who have not yet fully lost their reverence for authority. There is no physician, he continues, who would not regard it as trifling with a human life, when consulted on account of a dubious tumor in the breast, if he should wait for a long period of observation to watch the further development of the growth instead of insisting on its prompt excision and histologic examination. Gastric affections should be managed on the same principles. Every stomach affection which is not of a transient nature and for which no satisfactory explanation can be found, should suggest the possibility of cancer. And surgeons should reiterate constantly the necessity not only for an early diagnosis but for an early operation. He reports nine cases during the last year and a half with operative treatment. One of the patients was a woman of 34 with extensive carcinoma of the stomach. She had had recurring gastric symptoms for ten years; the cancer had evidently developed in an old ulcer. She has gained 11 pounds during the four months since operation. In another case the first symptoms had been observed four months before the operation, and the tumor required resection of the stomach and of the middle third of the transverse colon. The patient is now in good condition having gained 40 pounds in weight since. The colon stumps were united by lateral anastomosis, which seems, he thinks, to hold better than other technics.

85. Acute Atony of the Stomach.—Schlesinger reports an instructive case of acute atony of the stomach developing in consequence of the sudden sliding down of the viscera as the much debilitated patient got up the seventh day after an operation for retrodisplacement of the uterus. The symptoms subsided under repeated lavage of the stomach, the pelvis being kept raised. The special feature of the case, however, was the feculent vomiting; he regards this as proof that there could not have been occlusion of the upper bowel and, consequently, that the acute dilatation of the stomach could not have been secondary to an arteriomesenteric occlusion which some accept as the primary phenomenon in acute postoperative dilatation of the stomach. It is the first case on record, he says, in which acute atony of the stomach was unaccompanied by occlusion of the upper bowel. The case further shows, he declares, the beneficial action of raising the pelvis to remedy conditions, instead of the ventral decubitus which some have advocated for this purpose. With the pelvis raised it is much easier to rinse out the stomach; the stomach sinks down into its normal place and the small intestine follows it, thus relieving the traction on the mesentery. In another case, the pelvis was raised high for twenty-four hours, the patient being kept thus on the operating table for twenty-four hours, the stomach being rinsed out every hour at first and then at longer intervals. He thinks that anything less than these measures would have failed to save this patient. It is not enough to raise the pelvis occasionally for a time; it must be kept raised or the traction on the nerves and mesentery returns again. He never found it necessary to turn the patient on the side. An important adjuvant measure is to supply plenty of water by the rectum or by saline infusion. Large amounts of water accumulate in the stomach and are evacuated by the lavage, and it is of supreme importance to restore fluids to the body in some other way. Application of electricity to the stomach may also prove useful. In conclusion, Schlesinger reports experiments on dogs to induce acute atony of the stomach.

86. Acromegaly from Fright.—A fire in the home or gas explosion was the cause of the fright in the two cases reported. One patient was a housemaid, about 21 years old; the other was a woman of 31, six months pregnant. Menstruation was arrested at once in the case of the younger woman and there was no sign of the menses for several months, then only for two or three months; since then there has been complete amenorrhea. Menstruation did not return after the childbirth in the other case. The other symptoms of the acromegaly developed more gradually but the typical picture has persisted to date, four and sixteen years respectively after the fright.

92. Passive Exercise in Heart Disease.—Büdingen has been protesting for years against the application to actual heart disease of Oertel's method of exercise treatment for the obese with weak heart muscle. On the contrary, he insists, patients with heart disease should be guarded against the slightest extra demands on their hearts and should be kept in bed during periods of extra weakness on the part of the heart. At the same time it is important for them to exercise without the effort of voluntary movements. Exercising the legs is the best means in such cases to divert the blood from the heart, to improve the peripheral circulation and to stimulate the vital processes generally. He has been trying to contrive an apparatus which would exercise the patient without the slightest active participation on his part, and the apparatus as perfected after nearly two years' experiments is here described and illustrated. The patient lies on the back, the legs fitting into shallow troughs which are lifted in turn by the automatically working apparatus stationed at the foot of the bed and run by an electric motor, the patient being able to start and stop it at will by a touch to the chain in his hand. The movements imparted to the limbs are those of walking or hill climbing, and the patient can thus obtain the benefits of the active exercise without the least strain on his heart. Büdingen has the exercise applied two or three times a day for thirty or twenty minutes each time. The benefit in severe heart disease is surprising, even with ruptured compensation; the venous engorgement and edema subside, the liver returns to normal size and the signs of cardiac insufficiency rapidly retrogress. The apparatus has also rendered good service, he states, in cases of intermittent limping, of gout of the ankle, threatening diabetic gangrene and tabetic ataxia of the legs. Among the cases reported in which the passive exercises proved of special benefit is that of a physician of 47 who, before the age of 22, had had four attacks of febrile articular rheumatism which had left aortic insufficiency. Recurring endocarditis with fever nearly every day was kept under comparative control for a year by the bed rest and passive exercise, alcohol rubs and small doses of heart tonics. In other cases cited, the bed rest cure finally restored patients with mitral insufficiency to comparative health so that they could climb hills. Bed rest alone is not beneficial in cases of cardiac insufficiency with high blood-pressure, with or without kidney disease, but when the bed rest is supplemented by the vigorous passive exercise, conditions are improved as if by magic. It breaks up the vicious circle formed when the patient actively exercises while it gives the advantages of active exercise. In a particularly severe case described, the oliguria and dropsy had continued to increase notwithstanding that the patient had lain in bed for two months. Then the exercising apparatus was brought into use and in two more months the dropsy had drained away in the diuresis that followed the exercising and the general health was remarkably improved.

99. Traumatic and Renal Diabetes.—Weiland reports a case in which a wooden pail fell from a height of over 25 feet on the head of a man digging a well. He was unconscious for half an hour but the wound healed without further disturbances. A week after the accident, however, great lassitude, intolerable thirst, polyuria and pruritus developed and after another week the urine contained 4.7 per cent. of sugar. A year later the symptoms still persisted, with 1.7 per cent. sugar in the urine. The patient had been previously healthy, and came of a healthy family with no tendency to obesity or alcoholism. The progressive course of the diabetes in this case confirms the general assumption in regard to the comparatively rapid course of true traumatic diabetes. Weiland is inclined to regard the nervous shock of the accident as more of a causal factor than any pathologic changes at the site of the injury. He describes further three additional cases of renal diabetes, that is, persisting elimination of sugar in the urine without any apparent disturbance in the carbohydrate metabolism. The proportion of sugar in the blood was within normal range. The glycosuria was a casual discovery and the kidneys and other organs were apparently functioning normally. The special feature of the three cases was the lack of hyperglycemia and the absence of the usual subjective disturbances of diabetes, and of polyuria. The patients' weight persisted about the same throughout. It is possible that the diabetes in these cases may have existed long before its clinical discovery. He believes that some disturbance in the kidney parenchyma is probably responsible for this renal form of diabetes, the injury of the parenchyma escaping detection by our present methods of examination. Theoretically this renal diabetes may be classed with alkaptonuria and cystinuria, an anomaly not threatening the vital functions. He adds, in conclusion that it is better to refrain from excess in the articles of food liable to enhance the tendency to the anomaly. At the same time such patients should not be depressed with too stringent dietetic restrictions.

102. **Leukemia.**—Sternberg reviews the typical syndrome and discusses the treatment, emphasizing the importance of Roentgen-ray treatment and keeping the patient under constant supervision, so as to institute another course at the first signs of exacerbations. By this means it is possible to keep the patient in good condition with fair earning capacity for years. One of his patients was thus able to work at his trade of cabinet-maker for two years after comparative retrogression of the myeloid leukemia, dying then of ulcerative endocarditis. In another case a woman of 35 had been treated for weeks without benefit for symptoms suggesting influenza. A second physician was called and he found the spleen enlarged and diagnosed typhoid fever. The patient was anemic, feeble, with irregular fever, bronchitis, enlarged spleen and 450,000 small lymphocytes per c.mm. Roentgen-ray treatment was then applied and by the end of six weeks, the lymphocytes had dropped to 31,000 and the patient was able to take long walks, and this improvement has persisted to date, although the blood is not normal, the hemoglobin declining from 35 to 20 per cent. He is inclined to explain the action of the radiotherapy as partly direct, on the blood-producing organs, and partly indirect, by mediation of substances generated which have an inhibiting action on the production of leukocytes in parts of the blood-producing apparatus not exposed directly to the rays. In some conditions the rays have an opposite effect, that is, they may induce an affection of the blood and lymph-producing organs. Sternberg knows of four physicians who had worked considerably with Roentgen-rays who have died from leukemia or pseudoleukemia and lymphosarcoma. This coincidence must be more than merely casual; they all date from the days when Roentgenologists were less careful about protecting themselves than at present. Sternberg commends Roentgen exposures as the first measure in leukemia; for this institutional treatment is generally necessary, and hydrotherapy can be applied at the same time. During a pause in the radiotherapy or possibly with it, in case the affection is more of the neoplasm order, a course of arsenic may be useful, but he warns against arsenic poisoning, especially herpes, eczema and paralysis as manifestations of arsenic intoxication. The herpes may run into gangrene if the Roentgen exposures are kept up. In one case an eczema of the lips resisted all treatment until the arsenic was suspended, when it subsided at once. In a case of sarcomatosis with leukemic blood findings, the tumors subsided temporarily under large doses of arsenic but the arm became paralyzed and permanent paresis and tremor followed. It is his impression that arsenic is more liable to cause symptoms of intoxication when the lymph and blood-producing apparatus is diseased. He states that organotherapy and salvarsan have no action in leukemia. The main point in treatment is to commence it at the proper time and keep watch of the blood findings in case the leukocyte count is increasing, and suspend the exposures when the blood shows signs of a crisis or when myeloblasts appear in large numbers.

103. **Tumors in the Lungs and Pleura.**—Fraenkel reports three cases of pleural endothelioma leading to diffuse indurations. They all developed rapidly with extensive effusion, intensely hemorrhagic and accumulating again in a few days, and with intense pains, evidently due to traction from and the compressing action of the fibrous bands. In a fourth case the trouble was diagnosed during life as a carcinomatous pleurisy, the diagnosis being confirmed by necropsy. The patients were men between 37 and 48 and a woman of 66. Death followed in from one to two months after the first symptoms of trouble in the pleura.

104. **Treatment of Pancreatic Cysts.**—Körte reports six cases of inflammatory pseudocysts in which Gussenbauer's method of suturing to the skin and draining was successfully applied. In all of these cases the pancreatitis had several times induced symptoms suggesting gall-stone colic. The inflammatory or hemorrhagic effusion is not absorbed and benefit can be anticipated only from its prompt removal as soon as diagnosed. The trouble is in reality an encapsulated effusion or pseudocyst, and probably the cases of recovery reported from this technic have been in cases of this class. When the trouble is a true multilobular cystadenoma, this technic is not sufficient. It was applied twice in a case reported in detail, with only temporary benefit. Then the cystadenoma was radically removed and prompt recovery followed.

106. **Cystoscopy in Diagnosis of Pregnancy Pyelitis.**—Calmann reports four cases which confirm the importance of cystoscopy not only for early diagnosis of the pyelitis but in excluding appendicitis and cholecystitis, in locating the seat of the trouble and in permitting local treatment. In the first case, the patient had been treated for weeks for pregnancy disturbances and cystitis without avail; then cystoscopy disclosed slight hyperemia at the mouth of the right ureter and its catheterization evacuated pus and permitted local irrigation with 200 c.c. of a 1 to 2,000 solution of silver nitrate. All symptoms subsided at once. The same benefit was derived in the second case; the pyelitis developed here during the third month. In another case a chronic nephritis was left after the pyelitis which was in an advanced stage when local treatment was instituted. The macerated fetus was expelled three days after the local treatment; if this had been applied earlier, the death of the fetus might have been prevented as well as the development of the nephritis. It was a question in this case whether to interrupt the pregnancy or treat the kidney pelvis and he decided for the latter as briefer and milder. In two of the four cases the pyelitis was bilateral; in all the turn for the better that followed the disinfection of the pelvis was unmistakable, but a complete cure was not realized at once in any instance, the pus and bacteria persisting to a slight degree until a few weeks after delivery. It is possible that repetition of the procedure might cure completely. He does not advise this direct sterilization of the kidney pelvis as a routine procedure, but only when other measures have failed. It did not prove necessary in five other recent cases of pregnancy pyelitis in his experience.

107. **Eye Findings in Congenital Syphilis.**—Japha has made a practice of having the fundus of the eye examined in every infant showing a tendency to nervous disturbances, at the policlinic in his charge. Among 1,350 ophthalmic patients, in 1909, there were twenty cases of abnormal retina in infants with inherited syphilis, thus in 1.5 per cent. He found further that fully 66 per cent. of infants with inherited syphilis present anomalies in the fundus. Sometimes, with the Wassermann reaction, they are the only signs of the disease and they explain in many cases the convulsions, restlessness and constant crying of the infants. The findings in the fundus are generally bilateral but not always equally severe in both eyes. By this systematic examination, the optic neuritis is detected in its early stage, before it has reached the advanced phase. A peculiar rolling of the eyes, blinking or squint sometimes attracted attention to the eyes, or photophobia and twisting

the head to one side and trembling of the eyelids. The prognosis of the eye disturbance is *favorable if treatment is promptly instituted;* rapid improvement followed in nearly every instance after a course of mercurial treatment. For this he preferred internal administration of from 0.005 to 0.01 gm. of mercury protoiodid twice a day in two or three fifty-day courses. Recurrence was never observed although a number of the children were kept under supervision for years. Hirschberg, however, has *observed recurrence at the ages of* 13, 14 and 22. He only found one case of retinal changes from inherited syphilis in 1,000 ophthalmic patients. Among the typical cases reported by Japha is that of an infant whose only trouble was that it cried a great deal, especially at night. At the age of 3 months the eyes were examined and an areolar chorioiditis was discovered. As soon as antisyphilitic *treatment was started the child ceased crying.*

111. **Thyroiditis Following Iodid Treatment.**—Sellei reported in 1902 a *case in which inflammation and swelling developed* in a previously sound thyroid after the patients had taken 2 spoonfuls of a 5 per cent. solution of potassium iodid. The acute thyroiditis was accompanied by high fever. He here reports a similar case, the acute thyroiditis developing after the first spoonful and becoming more intense after 2 more spoonfuls. The iodid had been given in this case after a course of mercury. The thyroiditis subsided completely in a week. It was evidently a manifestation of iodism, the picture including palpitations and a pulse running up to 120. He is inclined to explain the symptoms as a manifestation of anaphylaxis.

117 *Anatomic Findings in Stomach of Infant Five Months After Cure of Stenosis of the Pylorus. J. Simon.
118 Two Cases of Congenital External Hydrocephalus. Z. v. Bokay.

112. ***Experimental Research on Injurious Influence of Prod*ucts of Decomposition of Urine.**—Raudnitz has been studying on animals brought up in the dark the development of a clonic spasm of the sternomastoid muscles when they are exposed to the light, the result being a sort of nodding spasm associated with nystagmus. He has also studied the influence of the products of decomposing urine, his attention being attracted to this line of research by a peculiar intense fragility of the bones observed in two children of a family that lived in a room adjoining the general urinal for a large factory, one wall of the room being constantly damp with decomposing urine. It proved impossible to induce in puppies any tendency to osteomalacia or rachitis even when kept *for eight months* in the fumes of their own decomposing urine.

117. ***State of Infant's Stomach Six Months* After Cure of Stenosis.**—The disturbances from stenosis of the pylorus in the case described had never been very severe, and they subsided completely under flaxseed poultices *renewed every two* hours. There was an inherited neuropathic taint, but after subsidence of the symptoms of stenosis the child thrived *normally* for six months but then died on the second day of an attack of pneu*monia.* The stomach was compared with the stomach of a normal child; the findings were extreme hypertrophy by excessive development of the musculature of *the* pylorus and stomach walls. The assumption of a primary hypertrophy of the stomach walls explains the anatomic, clinical and therapeutic data in *these cases* of stenosis of the pylorus in infants. The hypertrophy induces secondarily reflex spasmodic *contracture* of the musculature and thus entails the clinical picture.

124 Dietetic and Physical Measures in *Treatment of Kidney Disease.* (Nierenkrankheiten.) J. Hurter.
125 *Irritation of Optic Nerve by Salvarsan. (Zur Kasuistik der Salvarsantherapie.) A. Jansen.

120. **Early Diagnosis of Tuberculosis.**—Schwalm discusses whether the newer methods of diagnosis are of much assistance to the general practitioner, his conclusion being that the clinical examination of the patient is still as always the main reliance, and that the tuberculin test should not be applied except when there is some indication of incipient pulmonary tuberculosis and it is impossible to determine the facts in any other way. If the tuberculin test is applied, it should be by subcutaneous injection for adults and by the cutaneous method for children. The subcutaneous test should not be applied, he says, outside of an institution as close supervision of the patient is indispensable for its proper estimation; if the temperature is taken by the laity the findings are unreliable. He warns further to be on the watch for the pseudoreaction liable to occur in nervous patients; the only means to exclude it is by a control injection of water alone.

123. **Persisting Hiccup.**—In the case reported by Kanngiesser, the distressing hiccup came on during an attack of influenza in an elderly man. No benefit was derived from a subcutaneous injection of 0.001 gm. of atropin sulphate, which has been *recommended lately for this purpose;* in half an hour the patient's mouth became parched and he felt a burning in the nose but the hiccup was unmodified. After waiting for an hour and a quarter after the injection, the patient was then given in separate glasses a solution of 5 gm. citric acid and of 5 gm. sodium bicarbonate, hoping by the distention of the stomach from the effervescing fluids to act on the diaphragm *from below. The procedure was a complete success,* the hiccup ceasing at once. The patient was awakened in the night, however, by recurrence of the hiccup and repetition of this measure then failed to relieve, as did also the next day rhythmic traction of the tongue and holding the breath. He was then given a little sodium bicarbonate in water, *and the hiccup* ceased at once for a few hours, but returned then and *persisted until the patient* took some warm oatmeal gruel. This arrested the hiccup and had the same effect the next day when the hiccup returned, after which there was no further trouble. Kanngiesser appeals to other physicians to learn if they know of any better measures to arrest persisting hiccup.

125. **Irritation of Optic Nerve Under Salvarsan.**—Jansen states that several days after an intravenous injection of 0.4 gm. of salvarsan, the patient happened *casually to mention* that, commencing four hours after the injection, everything *seemed to waver* before his eyes for three hours. Jansen believes that if it were enquired for, this sign of irritation of the optic nerve (*heftiges Flimmern*) might be found frequent *after injection of this drug.*

126. **Gall-Stones.**—Kehr comments on the fact that no drugs or medical measures are able to act on the gall-stones themselves; all other measures but direct removal act merely on the conditions resulting from the presence of the stones, especially the inflammation. All that is possible is to keep the stones latent and answer the patient's four questions: "Have I gall-stones?" "Can you feel them?" "Must I have an operation?" and "Is the operation dangerous?" Only in exceptional cases, he continues, is it possible to state positively the presence of gall-stones. Even with his 1,668 gall-stone operations he still makes mistakes in diagnosis of cancer of the gall-bladder, especially when it is associated with empyema. With chronic empyema the temperature may be persistently within normal range in 50 per cent. of the cases. The history is of peculiar importance for the diagnosis of chronic empyema of the gall-bladder and chronic obstruction of the common bile duct, and he makes a point of writing it out and reading it over carefully two or three times to weigh it in all its bearings. A diagnosis based on the history is liable to be more correct than one based on the actual findings at the moment. In the written history we can follow the gall-bladder affection from simple serous cholecystitis to the obstruction of the cystic duct and the accumulation of pus in the gall-bladder, the passage of the stone into the common bile duct or its final perforation into the bowel, and we can trace the various stages of the affection by the presence or lack of jaundice and fever, swelling of the liver and pains. The localization of the pain is frequently misleading. In one case the only tender point was under the left costal arch, suggesting ulcer in the lesser curvature of the stomach, but the trouble was the result of numerous stones in the common bile duct. A high placed appendix may simulate cholecystitis. He states that he has been able to palpate the stones only in two or three out of his total 4,000 patients. Operative treatment is required more for the infectious process and to forestall its spread to other organs than to remove the stones themselves. This infection threatens the liver and pancreas and must be combated by removal of the focus in time, while it is still circumscribed. This is the main aim of treatment, and no time should be wasted with drugs and waters to which the power to dissolve or expel the stones is ascribed. Such measures should be left to quacks, and internists should cooperate with surgeons to check and cure the acute and chronic inflammation. This is best realized by moist heat, purgatives, restriction of the diet and repose, the cholelithiasis having a spontaneous tendency to return to a latent condition so that in 80 per cent. of all cases the colics finally subside spontaneously. The quack claims this 80 per cent. as his "cures," while the physician knows that Nature has wrought the cure and that it often is only a deceptive lull. The only radical cure is by removal of the infectious focus. Among Kehr's other reflections on gall-stone disease is the statement that when there is reason to suspect cancer in the gall-bladder, it is already too late for a radical cure; the patient is doomed. Only when in an operation for gall-stones, traces of incipient cancer are casually encountered, is the patient completely cured of the malignant disease. The loss of the gall-bladder causes no appreciable disturbances, and a new formation of gall-stones in the biliary ducts after cholecystectomy is so rare as to be negligible. Done in time, he reiterates, a gall-stone operation is practically free from danger.

127. **Chronic Constipation in Relation to Heart and Kidney Symptoms.**—Ebstein discusses the albuminuria and tube-casts liable to be found in the urine with chronic constipation or persisting coprostasis, and states that before attempting to estimate the prognosis of the kidney affection in such cases the intestinal functions should be regulated. The pathologic urine may be the result of toxic action from poisons generated in the intestines. The same statement applies to heart disturbances. When the heart is found enlarged or displaced, before assuming the presence of organic disease, conditions should be investigated to exclude displacement of the heart from the pushing up of the diaphragm from below. By removing the causes of this pushing up of the diaphragm—among which chronic constipation takes the first place—the symptoms on the part of the heart, even including those of cardiac insufficiency, may retrogress entirely. He recently reported subsidence of symptoms of exophthalmic goiter in four cases under treatment of chronic constipation by means of large enemas of oil. His report was summarized in THE JOURNAL, February 11, page 467.

128. **Diagnostic Inflation of the Stomach.**—Bardachzi reports from the medical clinic at Prague, in charge of Pribram, that inflation of the stomach with an effervescing mixture or with air alone has been systematically practiced there for years. In one case, however, the ingestion of the effervescing mixture was followed by severe hemorrhage from the stomach, and in another case by severe symptoms on the part of the heart from the pushing up of the diaphragm. Both patients were women in the fifties, and the alarming symptoms soon subsided. Behrend was less fortunate, Bardachzi remarks, as he lost three patients from this cause, the sudden distention inducing perforation of a gastric ulcer in two and of a carcinoma at the cardia in the third patient. For this reason Pribram has abandoned this method except in special cases, and prefers to distend the stomach with air alone. He interposes a glass jar with two mouths between the stomach tube and the tube with the double rubber bulb. If the patient retches during the inflation the vomitus collects in the interposed jar; this method of distention seems to be much less dangerous than with the effervescing mixture, while it permits graduated dosage. In the two mishaps Bardachzi reports, less than a teaspoonful of sodium bicarbonate and half a teaspoonful of tartaric acid were used for the test, each being dissolved in half a glass of water.

130. **Eosinophil Diarrhea in Infants.**—Langstein called attention in 1908 to the passage of mucus and pus by the bowels, occurring suddenly, the mass containing large amounts of eosinophil cells. In a case described here he noticed this sudden eosinophil intestinal crisis, as he calls it, as the first sign of the exudative diathesis; it was speedily followed by facial eczema. The mucopurulent stool in the infant, only a month old, would generally be considered a sign of severe intestinal derangement, but he regarded it as merely the expression of the diathesis and not of an alimentary disturbance in the ordinary sense. Consequently, he made no change in the diet except restricting the amount a little, and the further development of the child confirmed the correctness of these views. The intestinal crisis in these cases may be regarded as similar to what Strümpell calls intestinal asthma in infants; it is not accompanied by a rise in temperature or drop in weight—symptoms scarcely ever absent when it is a question of alimentary or infectious injury.

140 *Epidemic Endocarditis? (Kann die Endocarditis acuta epidemisch auftreten, und herrscht gegenwärtig eine solche Epidemie in Wien?) M. Herz.

140. **Epidemic Endocarditis.**—Herz states that he has seen so many cases of acute endocarditis at Vienna in the last few months that he asks whether it is possible for this disease to occur in epidemic form. The patients were all between the ages of 6 and 18 and the clinical course was alike in all, beginning with moderate fever without angina or joint symptoms; only later there were pains in one or both ankles in a few cases. Multiple articular rheumatism did not develop in any case, but in the second week there was tachycardia, accompanied later by palpitations, pains in the apex region,

rapid breathing and cyanosis. The myocardium behaved well, seldom showing much dilatation. Another symptom was a tormenting dry cough, especially at night, sometimes brought *on by eating and often followed by vomiting.*

147 Prevention and Treatment of Mediastinal Emphysema. M. Tiegel.

146. **Exposure of Nasopharynx.**—Krogius worked out on the cadaver several years ago the technic he describes with an illustration, and has been commending it for the clinic but only recently had opportunity to apply it himself on two patients. They bore the operation well and the further course was gratifying, while the operation itself was accompanied with remarkably slight loss of blood. It was done for removal of a fibroma in the nasopharynx in both instances. He applied part of the technic in a previous case two years ago but found an inoperable tumor in the pituitary body and the patient died the next day with pulmonary edema. The main features of the technic are the median incision of the lower jaw, enabling the two halves to be turned back on each side, the *tongue being drawn down over the cleft. The soft palate is* then separated from the hard palate by an incision curving across nearly to the teeth on each side. This permits the soft palate to be drawn down on the tongue quite out of the way, giving ample access to the nasopharynx through the gap thus left.

149 High and Low Epidural Anesthesia. (Hohe und tiefe extradurale Anästhesien.) H. Schlimpert.

148. **Anteflexion of Uterus in Origin of Myomas.**—Ott has had opportunity to watch over the later fate of large numbers of women with symptoms indicating anteflexion of the uterus. This experience has demonstrated beyond question, he states, that the venous engorgement and other interference with the circulation in an anteflexed uterus invite the development of myomas which are almost certain to follow. He declares, therefore, that anteflexion should no longer be regarded as a comparatively harmless anomaly which it is unnecessary to correct unless it is causing severe symptoms. It should be corrected without delay by medical or other measures, above all when changes in the parenchyma are already installed. Measures to regulate the circulation in the region, especially gynecologic massage, and measures to render conception possible, such as excision of the cervix, are the most important. In over a third of his patients treated with excision of the portio vaginalis on account of anteflexion, the women, long sterile, bore one or more children. The fibrous bands fastening the cervix in front have to be separated, and it is important, he says, to take the sutures at right angles to the line of the incision so that the row of sutures is sagittal to the cervix. A pregnancy transforms conditions and is the chief aim sought in treatment of anteflexion, and this transformation abolishes the conditions which unmolested lead to myomatous degeneration later. Ott thinks that it is absurd to seek for an explanation for the development of tumors which will apply to all; it is also absurd to reject a working hypothesis because it does not explain all kinds of conditions.

ROBERT KOCH THE FATHER OF MODERN TUBERCULOSIS SCIENCE[*]

S. ADOLPHUS KNOPF, M.D.

Professor of Phthisiotherapy, New York Post-Graduate Medical School and Hospital

NEW YORK

Koch's brilliant career as father of modern tuberculosis science began, of course, on that memorable evening of March 24, 1882, when he gave to the world the result of his painstaking work. It was the usual monthly meeting of the Physiologic Society of Berlin, but it was perhaps the largest gathering which that body ever had. Koch's paper was announced under the title, "The Etiology of Tuberculosis." Taking into consideration what Koch had given to science before along the same lines (I refer to the discovery of the spores of the anthrax bacillus and his concomitant bacteriologic studies), the hearers were, of course, expectant and looked for great things in store for them. It was characteristic of Koch's modesty and true scientific spirit that he had preferred to refrain from talking about his researches in tuberculosis until he could conclusively prove his thesis to the satisfaction of everyone and show absolutely accurate results. To students of bacteriology it must be recalled that Koch was the first to seek the production of a solid medium for the purpose of getting pure cultures, and it was only after he was in possession of such a medium that he attempted to isolate the germ found in tuberculous tissue.

It is of historical interest that on the evening of March 24, 1882, after Koch had finished reading his paper, there was no applause nor any enthusiastic manifestation of approval and for the first time in the history of that society, a paper, though listened to with the most profound and respectful silence, was not discussed. The facts presented by that master of bacteriologic science were too convincing for discussion. The audience looked expectantly to that most honored member and veteran debater, the father of cellular pathology, the immortal Rudolph Virchow, but he too remained silent. He felt that another great master in medicine had arisen and that the evidences of Koch's conclusions did not permit any doubt or dispute. The original communication announcing the discovery of the tubercle bacillus as the prime and only cause of tuberculosis appeared in the *Berliner klinische Wochenschrift* of 1882 (No. 15, p. 221). It is a masterpiece of scientific demonstration.

It may be interesting to some to know that access to an exact reproduction of this paper[1] can be obtained. The editors of the periodical referred to very justly stated that a more fitting memorial could not be printed at the time of Koch's death than that important paper which gave rise to all our modern tuberculosis research work, and at the same time gave to its author a well-deserved recognition and world-wide reputation.

In his paper Koch did not fail to pay tribute to the works of Villemin, Cohnheim, Salomonsen, Baumgarten and Tappeiner, who had given us conclusive proof that tuberculosis was a transmissible disease, but through Koch, and Koch alone, we have come to know the actual factor of infection and direct cause of all tuberculous diseases. It is he who showed us the presence of the germ in the pulmonary secretions and involved tissues, and also, to a minor degree, in other secretions of man and beast afflicted with tuberculosis. It is because of this knowledge that the new science which we might call modern prophylaxis of tuberculosis was created.

And now, after a lapse of nearly thirty years since the memorable discovery, we can statistically prove, beyond the shadow of a doubt, that, thanks to the rational, practical yet simple methods of prophylaxis which soon followed the discovery of the bacillus of tuberculosis by Robert Koch, the mortality from tuberculosis has been on a steady decrease in nearly all civilized countries.

When we consider that the present morbidity and mortality from tuberculosis in the countries which have adopted rigorous antituberculosis measures is in some instances two-thirds, and in some even one-half, what it formerly was, we must also admit that the material wealth which is the gain of thousands of communities, because Koch lived and labored, is beyond human calculation. Our sociologists and economists have estimated the value of a single human life as an economic asset of $5,000 to a community. Thus the figures in material gain to the world at large for which this one man is responsible must stagger our imagination. But we as physicians do not look on a life as representing a merely financial asset to the community. We come into too close contact with human suffering and sorrow for that. We rather emphasize the value of the discovery of our great Koch by the number of fathers, mothers, wives, husbands and children who were saved from an untimely death. We think of the tears and sorrow, of the anxiety and worry spared to untold numbers; we appreciate the joys and happiness which were preserved to thousands because the great white plague did not enter their homes. All this preservation of human joy and happiness has been brought about because of one single discovery of Koch, and the resulting indication of how to prevent disease.

But this phase of our medical science, which is truly preventive medicine, is not the only one whereby we as physicians and the world at large have been benefited by Koch's discovery. The presence of the bacillus in the sputum gives in doubtful cases a well-nigh irrefutable evidence of tuberculous infection of the respiratory

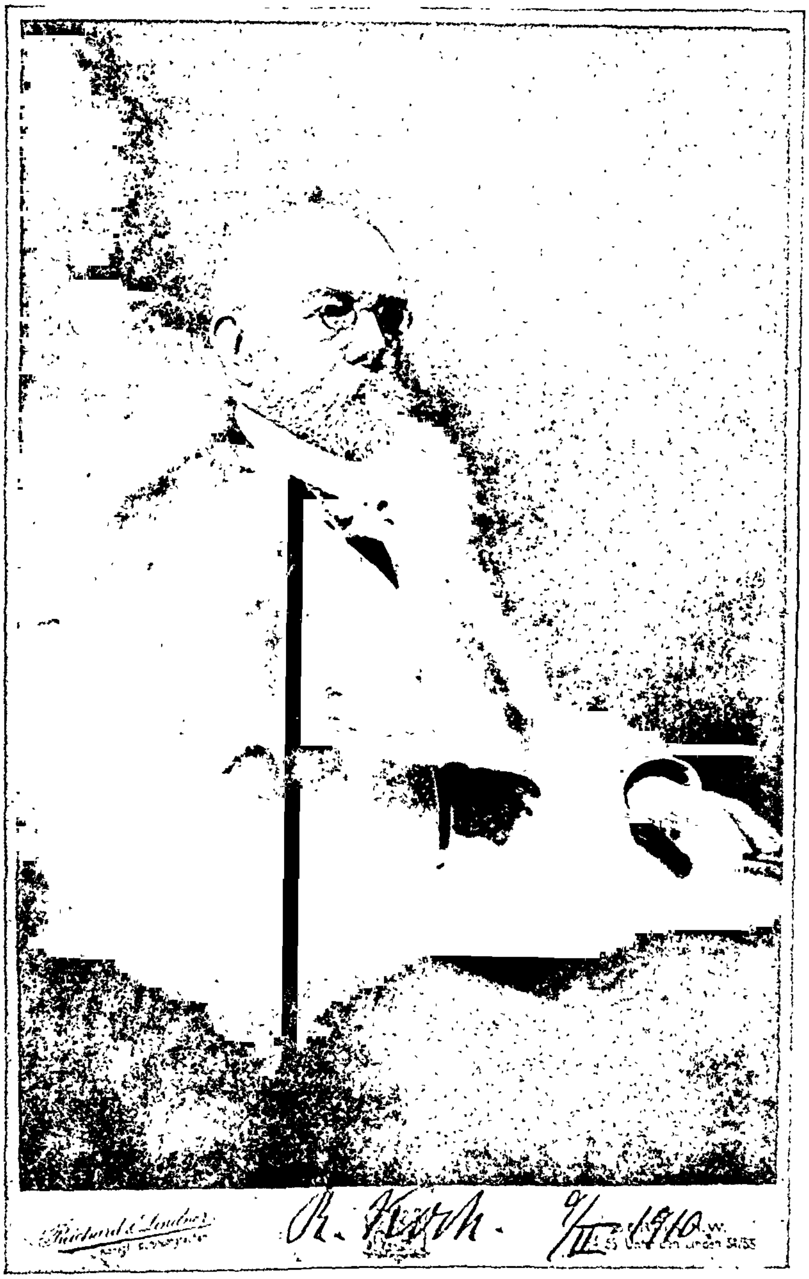
---

[*] Address delivered on the Koch-Memorial Evening, March 27, before the Laennec Society for the Study of Tuberculosis, of Johns Hopkins Medical School and Hospital, Baltimore.

[1] Ztschr. f. Tuberk., July, 1910, xvi, No. 2.

tract. In the discovery of tuberculin Koch has given us another adjuvant of great value in the diagnosis of tuberculosis diseases in man and animal.

A word regarding tuberculin as a therapeutic product. It is now generally conceded that when in 1890 Koch announced to the world the discovery of tuberculin as a means of curing tuberculosis, he did it against his better judgment, for he felt that he had not experimented with it long enough. The year 1890 was indeed an unhappy one in Koch's brilliant career. The powerful product used in far too large doses, by inexperienced men, indiscriminately in early and late cases, was followed by disastrous results. But time has justified Koch's original claim, and to-day his tuberculin in the hands of careful clinicians has certainly proved to be, in certain cases of tuberculosis, a valuable therapeutic adjuvant.



Koch did not limit his researches to the bacteriologic causes of tuberculosis or to the discovery of tuberculin, and it may be a surprise to many to learn what a deep interest he took in the sociologic aspect of tuberculosis. He studied all sides of the question — municipal control, popular education, the housing problem, etc. More than once did he express to me personally his approval of Professor Biggs' work in New York relating to the municipal control of tuberculosis, and he also referred to it in his celebrated London address in 1901. In regard to this communication made before the British Congress, justice requires us to say that Koch's conclusions as to the rarity of the transmission of bovine tuberculosis to human beings were too sweeping, this having been borne out by subsequent investigations. But had it not been for Koch's London address, much scientific work which has now cleared up the controversy would not have been done.

Koch's last contribution to the *Zeitschrift für Hygiene und Infektionskrankheiten* showed his deep interest in the sociologic aspect of tuberculosis. The article was entitled "The Epidemiology of Tuberculosis." In it he very justly ascribes the still very great prevalence of tuberculosis in certain sections of Europe to the unfortunate housing conditions and particularly to the overcrowded sleeping quarters of the masses. He also came to the conclusion that, where institutional care had been most readily available, the morbidity and mortality fron tuberculosis has been reduced to the greatest extent and *vice versa.*

Koch believed in popular education, and I hav received many a kindly word from him to encourage m in my humble labors in that direction. In his last lette to me, a few months before his death, he wrote:

> Popular works on tuberculosis are destined to play an important part in the enlightenment of the people, and the American people seem to be particularly susceptible to such education.

I hope we may deserve this gracious compliment paid to the American people by the great Koch.

And now, in conclusion, a few words on the personal side of this great man. On the evening of April 11, 1908, Koch was the guest of the German Medical Society of New York. It was indeed a distinguished gathering. Professor Karl Beck, as the president of the society, was the toastmaster of the evening. Your own distinguished teacher, Professor Welch, being one of Koch's first pupils, welcomed the great scientist to our shores, and spoke in eloquent words of the achievements of his master. Equal praises were bestowed on Koch by the Nestor of the New York and the entire American medical profession, Prof. Abraham Jacobi. Andrew Carnegie, the philanthropist, who had given 500,000 marks for the Koch Institute in Berlin, praised Koch as a hero of civilization and peace, far greater than a hero in war, and concluded by saying:

> Every age has its ideals, and the servants and saviors of mankind are our present-day ideals, for I firmly believe that service to mankind is the highest service to God.

And what did the great Koch reply to all this praise and eulogy? His answer was of so inspiring and modest a character that I believe it to be worth while to reproduce it in the original words which will be found below. I will also translate it into English as exactly as possible:

> When I now consider the honor you have conferred upon me here this evening, when I consider all that has been said and done in my praise, there arises in my mind a doubt as to whether I am really entitled to such distinction. Some of the kind things which have been said of me I believe I may accept with a clear conscience, but I have done nothing else than what you are doing every day. I have worked as hard as I could and have fulfilled my duty and obligations. If the success really

was greater than is usually the case, the reason for it is to be found in the fact that in my wanderings through the medical field I came on regions where gold was still lying by the wayside. Fortune is necessary to be able to distinguish gold from the base metals, but that is no great merit. I am glad to see Mr. Carnegie here, whose generous gift to the Koch Foundation in Berlin made everywhere such a deep impression. I would wish to thank Mr. Carnegie with all my heart. The foundation which is to bear my name is, I hope, destined to show great results in the field of tuberculosis research. While special hospitals and sanatoriums for the treatment of tuberculosis are of local importance in the combat against tuberculosis, the Koch Institute or Foundation is destined to study the underlying causes and as yet unsolved problems of the disease and thus will benefit mankind at large.[2]

Koch had a remarkable genius for research work, yet his aim was always eminently practical and his sympathies genuine and real. By hard work and diligent application he revealed the hidden mysteries of disease.

Koch was not privileged to see the foundation for further tuberculosis research work, bearing his name, completed. He died May 27, surrounded by devoted pupils and friends. By indubitable right he now takes his place with the immortals and his name will be handed down through generations to come as one who has lived and labored for the good of mankind.

In accordance with Koch's last request, his funeral was of the simplest kind, and as an enthusiastic sanitarian he had directed his body to be cremated. His admirers and pupils gathered the ashes of the beloved master and enshrined them in a mausoleum located in the Institut für Infektionskrankheiten in Berlin, of which Koch had been director for many years.

I venture to say that for generations to come, all physicians, and likewise the many men and women outside of the profession who are interested in scientific or preventive medicine will, on visiting Berlin, deem it a pious duty to make a pilgrimage to this last resting-place of the ashes of Robert Koch.

A CLINICAL STUDY OF SPOROTRICHOSIS

WITH A REPORT OF FOUR CASES

J. M. SUTTON, M.D.

HALSTEAD, KAN.

During the past few months several articles dealing with sporotrichosis in man have appeared in the American literature.[1] Evidently the disease is not so rare as was supposed. Practically all these cases have been seen in farmers and stockmen. The disease seems fairly prevalent in rural districts, and if it is to be successfully treated the nature of the infection must be recognized.

It is possible that cases of sporotrichosis have been diagnosed as tuberculous lymphangitis.[2] Unfortunately, the infection is usually treated surgically and the patient undergoes weeks or months of needless suffering.

As previous writers have pointed out, a traumatic lesion of the arm, hand or forearm which proves resistant to ordinary surgical treatment and is accompanied by the development of one or more sharply defined, painless, cutaneous or subcutaneous abscesses along the course of the lymphatics should always arouse suspicion, especially if the inflammatory manifestations of a coccic infection are absent.

It is well to remember (as occurred in one of the following cases) a concurrent infection of the ordinary pus germs may develop as a result of repeated surgi procedure and thus mask the typical symptoms of primary trouble.

The organism consists of a branching, septate, coa mycelium, from which ovoid bodies develop by buddi either from lateral or terminal filaments or from sides of the threads. These ovoid bodies are spores (F 3, Case 1).

Lutz and Splendorie[3] report the presence of t fungus in the mucous membrane of the mouth of healt rats; they ascribe the occurrence of cutaneous spo trichosis of rats to infection from bites. Rather ext sive experiments have shown rats and mice to be m susceptible; cats, dogs and rabbits negative; guinea-p susceptible, but less so than rats and mice. Intrape toneal injection in guinea-pigs failed to produce the case, while in the case of rats the organism was recov from the circulating blood as well as from diff tissues of the body. They found the growth to be scanty and slow, forty-eight to seventy-two hours ing before a few colonies were seen. They cul the fungi on all ordinary media both acid and all in reaction. The optimum temperature was found 28 C., though a much slower growth still occurr C. Growth was not inhibited by the addition cent. tartaric acid and this substance was obtain a pure culture. The addition of grape the media produced a more luxuriant growth. his late work, notes the fact that Norris a found difficulty in growing the streptothrix tried fresh sterile kidney tissue of rabbits.

Trimble and Shaw report a case of sporot tion and mention the fact that when cult ficially the surface of the growth becom turning brown to black with age.

In all of the following cases, which ca observation during the past year, diagno by microscopic examination:

CASE 1.—H. G. J., laborer, aged 52, m personal history good, had never suffere physical examination was otherwise neg previous to consultation, while tearing patient received a puncture wound in from a small nail which penetrated d little trouble and was not regarded prompt. Three weeks later a nodule hand opposite site of puncture. Th diameter, 0.5 cm. elevated, slightly and sharply circumscribed; dark r fluctuation was evident. No inflan tissue was present and no areola the following week successive r (Figs. 1 and 2), twenty-four in nun

CAUSES AND PREVENTION OF DEATHS DUE TO ANESTHESIA

Deaths from anesthetics are said to be on the increase both in this country and abroad. The fact cannot be gainsaid that chloroform occasionally proves fatal in the hands of the most careful and expert anesthetists. A fruitful source of deaths is the administration of anesthetics by untrained administrators and by those who have had a fair training, but are careless, poor observers, or are overconfident in the safety of the drug they are using. At present we have no absolutely safe anesthetic, and as this is an age of activity along research lines new anesthetic agents or combinations are suggested and tried. Questionable methods of producing anesthesia are responsible for a large number of deaths. Then, too, surgeons are frequently at fault in insisting on a deeper narcosis than is safe, particularly when an inexperienced individual is acting as anesthetist.

The remedy for these evils must be education. Both didactic and practical instruction in the use of anesthetics should be made an obligatory part of the medical curriculum. The didactic instruction should consist of a description of the various drugs used for anesthesia, their action, and methods of administration, preparation of the patient, selection of the anesthetic, after effects and their treatment and how to avoid and deal with anesthetic accidents. The practical instruction should consist in the administration of anesthetics under competent guidance.

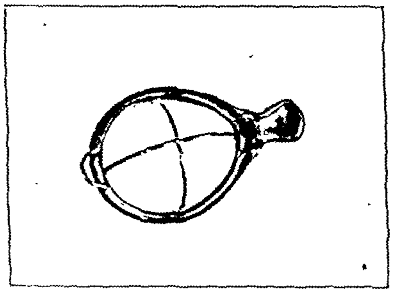

Fig. 1.—Schimmelbusch anesthesia mask.

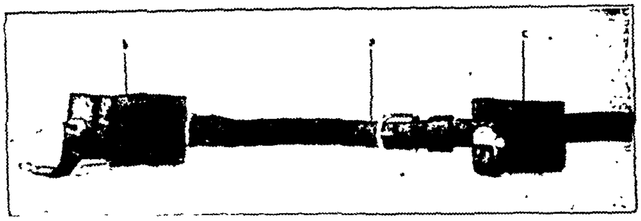
Every hospital in which operations are performed should have on its staff a paid anesthetist, who should be given complete charge of the administration of anesthetics. It should be his duty to visit operating-rooms during operations and instruct, make suggestions to or correct interns in their anesthetic work, and see that they do not perpetuate the evil practices handed down by their predecessors. He should administer all anesthetics requiring special skill. In the latter instance he should receive extra remuneration from all except charity patients.

Unfortunately most anesthetists receive their meager instruction from surgeons, during the operations, and it is a notorious fact that the majority of surgeons are poor anesthetists. From the fact that a man operates hundreds of times a year it does not follow that he is proficient in the art of producing and maintaining anesthesia any more than from the fact that a professional anesthetist glances occasionally at the field of operation it follows that he should become proficient in the art of surgery.

COMPARATIVE SAFETY OF CHLOROFORM AND ETHER

Unprejudiced investigations have placed the comparative safety of chloroform and ether on a firmer basis and it is now quite generally conceded that the limitations of chloroform have been markedly increased while those of ether have been decreased. Clinical results and careful research work conclusively show, not only that death during chloroform administration is much more frequent than when ether is used, but that evil after-effects are quite as common and much more serious. Experimentally it has been found that about 70 per cent. of animals anesthetized with chloroform show liver changes varying from fatty degeneration to necrosis. The degree of destruction seems to bear some relationship to the length of the narcosis, and especially to repeated anesthetizations. The changes usually begin in the center of the lobule and may extend till all the liver cells become more or less affected.



'Fig. 2.—Restraint straps for use in anesthesia: a, central strap showing adjustment buckle; b, cuff opened showing clasp fastener; c, cuff closed.

In the human subject the symptoms of late poisoning develop two or three days after the narcosis, in patients who have shown no evil effect from the operative procedures. Death occurs in four or five days. Autopsy reveals small hemorrhagic foci in the gastro-intestinal tract, mesentery, omentum, pleura, pericardium. Kidney epithelium is swollen, contains fat droplets or is necrotic, no inflammatory changes being present. The most marked change, however, is found in the liver. The lobules are decreased in size, the parenchyma cells may be completely destroyed through fatty degeneration or necrosis, but no evidence of acute or chronic inflammation or change in the bile-ducts is present. Persons in good general physical condition are quite as apt to succumb to the poisonous effects of chloroform as the debilitated. The majority of reported deaths occurred before middle life. As the question of safety is of paramount importance and should dominate all others in the selection of an anesthetic, no one is justified in using chloroform except for definite reasons, or under peculiar circumstances. It should be remembered that the more chronic a lesion is the less important it is as a contraindication to the use of ether.

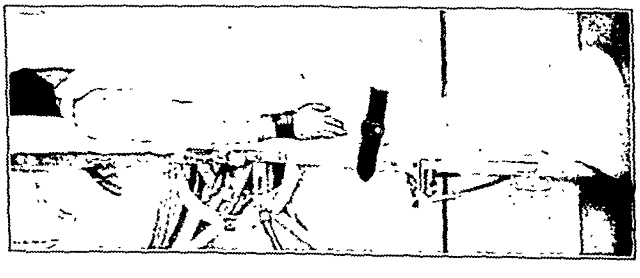


Fig. 3.—Patient in position for operation with restraint straps adjusted, including a simple canvas surcingle about the knees.

NURSES AS ANESTHETISTS

Nurses when properly trained make very good anesthetizers and frequently their technic becomes quite perfect. But they work at very great disadvantage. Because of their lack of medical training, they are unable to weigh physical findings, and not being familiar with operative procedures, they are unable to decide which anesthetic is the safest in a particular case, or which will produce for the surgeon the best operative conditions. Consequently the question resolves itself into one anesthetic in all classes of cases and no hope of advancement or research work can be expected.

It may be urged that surgeons prefer selecting the anesthetic, which is generally true because there are so few anesthetists capable of taking the full responsibility of the anesthetic end, as the surgeon does the surgical end. This is not the case where medically qualified professional anesthetists are employed who are never slave to any one anesthetic, but select in a logical manner the agent best suited to the case in hand.

SHALL THE ANESTHETIZER OBSERVE THE OPERATION?

It has been stated that the anesthetizer should never look at the operative field, but should keep his eye riveted on the patient's face. This is a serious mistake, for unless one keeps in touch with the operator, he cannot interpret changes in the circulation and respiration which are directly due to operative procedures. Neither can he tell the degree of narcosis indicated for the operation in hand throughout, or at different periods, and the patients are kept either too profoundly asleep or move or show some sign of too light an anesthesia at a most inopportune moment. I do not mean that every step of the operation should be watched, but an occasional glance at the operative field will keep one posted.

REFLEXES AND INHIBITIONS

Reflexes and respiratory inhibitions are of great importance and should be understood by operators and anesthetists. The region supplied by the superior laryngeal nerve appears to be especially endowed with inhibitory impulses, as is frequently demonstrated in operations about the larynx and pharynx. Swabbing out the throat during anesthesia is occasionally followed by a suspension of respiration. This inhibition, it is true, usually passes off quickly, but it causes consternation, and artificial respiration, with all its attendant commotion, may be instituted before the patient is again breathing in a regular manner. If the patient's head is turned to the side, any mucus which could be reached with a swab will flow out at the angle of the mouth. Modified respiration, due to peripheral impulses, is well demonstrated in exploratory laparotomies, as the examining hand passes from one region to another. Increased, but noiseless, respiration is immediately produced on contact with the peritoneum. Manipulation about the diaphragm causes noisy expiration, while manipulation about the pelvis, sigmoid, rectum and anus causes a prolonged inspiration. Perhaps no reflex action causes the impatient surgeon so much annoyance as the almost explosive expiration caused by manipulations of the intestine, in an effort to replace it in the abdominal cavity. Surgeons usually attribute the difficulty to imperfect narcosis, but if they will cease manipulations for a few moments until the reflex action disappears, they will experience no trouble in returning the bowel through the incision.

OPEN METHOD OF ETHERIZATION

In 1898, I reported to this society a new method of etherization which I had employed in a thousand administrations while in the service of Dr. A. J. Ochsner. Four or five years preceding my observations, Dr. Lawrence H. Prince, the originator of the method, had used it in two series of cases of 500 each. In his published articles may be found a description of the technic employed. The superiority of the method is evidenced by its steady growth in popularity, not only in this country, but also abroad. I have used this "open" method of etherization, as Dr. Prince suggested, with one or two unimportant modifications in over 15,000 anesthetizations. I feel, as I did at the end of my first trial thousand, that when properly used it is in all respects ideal. At the time Dr. Prince demonstrated the possibility of giving ether similarly to chloroform, the only mask on the market was the Esmarch. At present there are so many styles that it is difficult for an inexperienced anesthetizer to select one. I prefer the Schimmelbusch (Fig. 1). The weight is about right to make it easily kept on the face, the shape is good and it is sufficiently large to cover the mouth and nose without being cumbersome or complicated, as is, for instance, the mask suggested by Ferguson. Having no handle or nose-piece it can be used with the patient in any position on the table, or for any operation about the nose or face, except mouth or jaw operations.

I cover the mask with two layers of stockinet—medium quality—and this is all that should be used or is necessary except in cases of alcoholics. With the latter class of patients, it is usually necessary to place three or four layers of gauze over the stockinet, which should be removed as soon as the individual passes the stage of excitement. Placing ten, fifteen or twenty layers of gauze over the stockinet is not only unnecessary, but it approaches the old "closed" method, except that the ether is dropped on the outside to evaporate, while the patient reinhales his own breath from within, instead of the ether being poured inside of the cone and the patient allowed to breathe it and his carbon dioxid as was the case with the old method of etherization. Dr. Prince advocated allowing as much air with the ether as was consistent with anesthetization, thereby reducing the immediate and after ill effects of the drug. It goes without saying that the more gauze one has over the mask the less air the patient receives and the more carbon dioxid he inhales.

RESTRAINT STRAPS

I desire to call your attention to a very humane and simple, but efficient, device used in insane asylums for restraining patients. We have found it an almost invaluable addition to our anesthetic armamentarium. The strap consists of a central piece of leather provided with a buckle, which allows the strap to be adjusted to the width of the individual's hip. At either end of the strap are attached cuffs with clasp fasteners. The cuff, like the central strap, can be adjusted to fit different sized wrists. The patient lies on the central strap with the hands placed at his sides, with the cuffs about his wrists. This is a comfortable position for the patient: the hands are out of the way of the operator; and it is impossible for them to fall off the table causing a possible pressure-paralysis. It is also impossible during the stage of excitement for the patient to use his hands. Furthermore, if a change of position for operative purposes, or if artificial respiration, should become necessary, the hands can be loosened almost instantaneously.

In addition to this strap we use an ordinary surcingle. This should be placed rather snugly just above the knees. If placed below the knees the patient will be able to work the limbs from under it. With these two restraint straps one person can manage the worst alcoholic during the stage of excitement with absolutely no danger of his getting off the table.

DRUGGING BEFORE GENERAL ANESTHESIA

I wish to protest against the routine giving of drugs before ether and chloroform anesthesia. In selected cases it may be of advantage, but the system can eliminate one poison much more easily than it can three or four at the same time. The use of morphin with atropin or with hyoscin (scopolamin) in combination with ether or chloroform is absolutely detrimental in many instances. It is a well-known therapeutic fact that one drug may augment the action of another, and this is especially so in an ether or chloroform-morphin combination. Consequently, an overdose is more easily administered. The excessive action may be undesirable or dangerous. A number of instances have been reported, in which alarming respiratory depressions, or even deaths have been attributed to this method. In cases of any untoward accident, there is not only the volatile and quickly removable drug, but also the non-volatile and comparatively permanent one to be eliminated. Many former advocates have abandoned the method because of deaths reported by competent anesthetizers, which were due to the more permanent drug, although small doses were given.

Not the least of the objectionable features of drugging before general anesthesia is the masking of the most valuable of all guides in anesthesia, namely, the pupillary reaction. With a single drug, as ether, or chloroform, one can interpret every change in respiration and circulation, meet and combat it; not so when several drugs are acting and one has no way of knowing which is the guilty one. Because less chloroform or ether is required when combined with morphin and atropin or scopolamin, the combination has been recommended in mouth operations, but that advantage is more than offset by the disadvantages of the patient's remaining asleep after the operation is completed. Morphin allays the reflex excitability of the air passages, thus retarding coughing and favoring the retention of aspirated blood or vomitus in the trachea or bronchi, which predisposes to pneumonia. Many people are unable to take morphin without distress or vomiting, and in such individuals the disagreeable after-effects of ether or chloroform would be aggravated. If the lovers of atropin will keep the patient's head turned to the side, troublesome mucus will escape at the angle of the mouth or remain in the cheek where it can be wiped out. This position also prevents the tongue from falling back and obstructing respiration. Occasionally, mucus collects in the bronchi, in which case the patient should be allowed to awaken sufficiently to cough. Mucus acts as a foreign substance and causes reflex coughing, although the patient may still be fairly well anesthetized. They very quickly become narcotized again. The much-lauded quieting effect of combination anesthesia, making the patient come to the operating-room in a tranquil frame of mind, is of little moment compared with the disadvantages of the method. The practice is a reversion to the old time "shot-gun prescription," and should be placed on the shelf with the "tried and found wanting." Occasionally at the end of long, difficult operations on debilitated patients, a stimulant may be indicated. Strychnin has given me the best satisfaction of any drug. It acts in an ideal manner on respiration and circulation in a remarkably short time. However, most patients respond nicely to warm saline solutions given per rectum, especially if there has been much hemorrhage. This has the added advantage of supplying fluid, thereby relieving thirst.

FAMILY PERNICIOUS ANEMIA

THREE FATAL CASES OF PRIMARY ANEMIA (TWO BROTHERS AND ONE SISTER) AND TWO OF SECONDARY ANEMIA (TWO SISTERS) IN MEMBERS OF ONE FAMILY; FATAL PRIMARY ANEMIA IN A PATERNAL COUSIN; A FIFTH CASE OF FATAL PRIMARY ANEMIA IN A PATERNAL UNCLE.

ARTHUR J. PATEK, M.D.
MILWAUKEE, WIS.

The title of this paper well defines an interesting series of cases that have come under my personal observation. I have nothing to add to the existing theories of the causation of true pernicious anemia. That the immediate active factor is some hemolysin, is probably uncontradicted, but the mystery of the ultimate cause is still unsolved. William Hunter has emphasized the important rôle played by septic conditions of the mouth and tongue. Grawitz records four cases based on his view of the intestinal origin of the disease. It is further stated (Edwards) that such conditions as "pregnancy and the puerperium, syphilis, poor hygiene, infectious diseases—as typhoid and malaria"—are causative. But the astonishing and absolute increase in the incidence of the disease would seem to warrant a belief that these must be considered rather as bearing an associated than an etiologic relation to primary anemia. On the other hand, intestinal parasitism may with justice be viewed as the only known demonstrable cause. Unfortunately, even this series, here reported, of five cases in one family, permits of no deductions as to etiology.

Pernicious anemia is no longer to be considered of infrequent occurrence, and, unless a particular instance of the disease present unusual features, its detailed history would hardly be warranted. The noteworthy feature of the report here given is that—as far as I can ascertain—medical annals contain no similar observation. A careful search has revealed but a single instance bearing on heredity in pernicious anemia; this statement[1] quotes "an observation of Klein's, who saw a brother and sister succumb to progressive pernicious anemia." Another published report by Sinkler and Eschner[2] of "three cases of pernicious anemia in one family," may be disregarded because no evidence is adduced warranting their deductions; in fact, but one case of genuine pernicious anemia is admissible, and their report has been quite generally discredited as not justifying the claim made. The single previously recorded instance, therefore, of two cases—a brother and sister—in one family, lends added interest to my observation, which, briefly summarized, is as follows:

Three fatal cases of primary anemia (two brothers and one sister) and two of secondary anemia (two sisters) in members of one family; primary anemia in a paternal cousin; a fifth case of fatal primary anemia in a paternal uncle.

Family History.—The mother of the patients here spoken of as Patients 1, 2 and 3 is 78 years old, and is well. Their father died about fifteen years ago, at the age of 52, after an illness of about two years' duration. The cause of his death was variously stated by the family as Bright's disease, liver disease, and "complications." He was not dropsical. The surviving brothers and sisters, after witnessing the gradual development of the fatal anemia in one brother and one sister, have expressed the belief that their father may have died of a similar train of symptoms. This is merely a conjecture on their part and of no value as evidence. A brother of the father of my patients died after the death of my patient (Case 2) of what was recognized as pernicious anemia. (See below, Case 7.)

---

[1] Nothnagel's Encyclopedia of Practical Medicine, Volume on Diseases of the Blood, p. 233.

[2] Sinkler and Eschner: Am. Jour. Med. Sc., 1896, p. 287.

The course of this family scourge can best be developed as we follow the histories in brief of the individual members, five brothers and sisters, all of whom have at various times been under my observation, and of two members of collateral branches of the family.

Case 1.—Primary anemia. *Summary.*—Male, aged 35; several remissions during a period of one year; typical blood-findings; lowest red blood-count 650,000, hemoglobin 20 per cent. Died with symptoms of an acute terminal infection—probably endocarditis.

History.—This patient's personal history prior to the fall of 1899 is unimportant. In the summer of 1899 he submitted to an examination for life insurance, and on a very carefully executed test was granted the policy applied for. It is possible that a degree of pallor existed even at this time; but the man was a blond and the pallor may not have been sufficiently striking to warrant a suspicion of its pathologic character. The anemia increased in intensity and was attended with great weakness. He improved markedly in the fall, but suffered a second relapse in December of that year. He was under the care of a competent physician at this time, and the diagnosis "pernicious anemia" was made. I was later informed that during the period of severe illness in this first summer his blood had been reduced to 20 per cent hemoglobin, and 1,500,000 erythrocyte count, but that in the fall the hemoglobin had again mounted to 80 per cent. Feb. 23, 1900, he consulted me. He then complained of feeling very weak, and of having had what he termed an attack of "grip." The history gave evidence of similar previous attacks. This periodic disability consisted of weakness, pain and soreness in the limbs, slight elevation of temperature, and gastric uneasiness.

Examinations.—At this time he looked quite fleshy and his face was round and full, this fleshy but flabby appearance persisting to the end. The skin and the conjunctival and oral mucous surfaces exhibited great pallor. No hemorrhages were noted. Hemoglobin 45 per cent, erythrocytes 1,880,000; color index 1.2. There was no history of malaria or of any other infectious disease, and no evidence of endocarditis or gastric disease. Hemic (?) murmurs were present. The blood picture was at this time quite convincing of an anemia of the pernicious type. Micro-macro-poikilocytes were present to a moderate degree; few nucleated red corpuscles were found. After a lapse of one week I was again consulted. The patient had been having another attack of what he termed "grip": his knees, ankles and wrists were somewhat stiff and lame, though not swollen or tender; his temperature had reached 105 F. the previous day, and was now 103 F. The conjunctivæ were very yellow, the skin of a similar tint. The spleen was enlarged, liver normal in size and not tender, a systolic heart murmur, heard loudest at third left interspace, was present; lungs were normal. A venous hum was very prominent. The urine contained a trace of albumin, but no organic sediment. Three days later the patient developed a cough, and a little frothy, blood-streaked mucus was expectorated. Labial herpes was present. Crepitation was found at right base posteriorly. but no bronchial breathing or dulness; respirations 30 per minute; epistaxis. Blood examined at this time revealed numerous normoblasts and megaloblasts, marked poikilocytosis; erythrocytes 1,175,000; hemoglobin 32 per cent; color-index 1.36. All pulmonary signs and symptoms disappeared in a few days and the temperature dropped to 100 F. The general condition seemed improved, though the blood-picture was disappointing; erythrocytes, 635,000; hemoglobin, 28 per cent; color index, 1.97. Though no white blood-count was made, the smears showed quite conclusively that a leukocytosis existed. Differential count: polymorphonuclears 68, mononuclears (large and small) 27, myelocytes 5. (In pernicious anemia there is usually a reduction in the number of leukocytes, the lymphocytes being relatively increased. The findings in this case are due to the complicating infection.)

Course of Disease.—Under careful medication with arsenic, iron and strychnin the blood picture changed to: erythrocytes. 1,220,000; hemoglobin, 32 per cent; color index, 1.31. There now developed considerable abdominal distention and quite acute epigastric sensitiveness. Peritonitis was suspected. and the suspicion verified the next day when all previous signs had become much accentuated, and abdominal fluid detected. All symptoms became intensified, and death resulted three days later, in a condition of profound asthenia.

Necropsy.—Permission to perform an autopsy was granted, but, to my keen regret, with the provision that it be done as long after embalming as possible, and just before burial, so that the appearance of the deceased be restored to as nearly a perfect condition as the embalmer's art could make it. I found, forty-eight hours after death, that the process had been so skilfully done as to make a proper recognition of conditions as they had existed ante mortem quite impossible. Pulmonary adhesions were found at the right apex anteriorly; no signs of consolidation or infarction. The heart was so filled with formalinized blood, and the valves so brittle and hard and clotty, that their examination led to no conclusion. The heart muscle was pale. In the abdomen there was serous fluid, and the intestines were covered with a fibrinous exudate; the liver was enlarged and covered with exudate; kidneys large and white; spleen twice normal size; no intestinal ulcers discoverable. The bone-marrow was red and soft and contained numerous multinucleated megaloblasts (gigantoblasts), identical with those found in the circulating blood. All the abdominal organs—including the pancreas—were so matted together and hardened by impregnation with formaldehyd solution that it was impossible to get more than a superficial idea of the pathologic conditions that existed. The exact nature of the intercurrent infection that terminated this case of pernicious anemia can be but conjecturally made, and it is possible only to surmise the diagnosis from the clinical symptoms. The probability of its having been a terminal endocarditis is apparent.

Should it be at all necessary to defend the stand that this was primarily a case of pernicious anemia, and not primarily an infectious endocarditis, I would emphasize these facts: the absence of any heart murmurs in the summer of 1899; the remissions in the disease during the latter half of that year; the patient's general appearance; the blood-findings made by competent observers; my own blood examinations showing a very high color-index; the numerous nucleated red corpuscles, and especially the large number of megaloblasts; the condition of the bone-marrow. The relative increase in polymorphonucleated leukocytes was due to the terminal infection.

Case 2.—Primary anemia. *Summary.*—Mrs. J., aged 45, sister of Patient 1. Three remissions; typical blood-findings; erythrocytes 520,000, hemoglobin 15 per cent.

History.—I first made this patient's acquaintance at her brother's bedside. She was fleshy, of rosy complexion, was feeling and looking well. The only noticeable feature was a slight and fairly constant tremor of the head. I was called professionally in consultation in July, 1902, two years and four months after her brother's death. In the patient's personal history there was nothing noteworthy. For a period of about five months previously she had been in poor health and had complained of considerable weakness. Pallor had existed to a prominent degree, though this had fluctuated in intensity. Two months previously the patient had gained in health, but the improvement was very evanescent, and she soon relapsed into her former state of ill health. She had now been in bed six weeks. There was a daily rise of evening temperature to 100 F. She complained of no pain, but of slight gastric distress and occasional headaches. Sight was good.

Examination.—The face had a pasty appearance, skin pale and yellowish (not icteric), conjunctival and buccal mucous membranes very pale. No petechiæ were noted. There was some puffiness about the eyelids—a probable result of the long-continued use of arsenic. There had been slight edema over the tibiæ, though this did not now exist. Neither the long bones nor the sternum were sensitive to touch. Soft systolic murmurs were heard over all valves, and jugular venous hum was prominent. The spleen was enlarged upward; abdomen otherwise negative; urine pale, sp. gr. 1,008; albumin in small amount, but not more than could be accounted for by the presence of bladder-cells and pus. No casts. *Blood examination:* erythrocytes, 1,500,000; hemoglobin, 40 per cent.; color-index, 1.3: micro-macro- and poikilocytes; few normoblasts. Polymorphonuclears, 80; lymphocytes, 20. A diagnosis of pernicious anemia was made, but only reluctantly concurred in by the physician in charge. The patient herself feared that her condition might be similar to that which had proved fatal in her brother's case.

Course of Disease.—Arsenic was given. I saw the patient again three weeks later, and found her much improved. The blood examination registered a red count of 2,450,000, hemoglobin 65 per cent., color-index 1.2. Her general appearance was better and she was more hopeful. Four months later she was attending to her Christmas purchases, was the picture of perfect health, felt well and strong; her cheeks were so rosy that one might well have doubted the correctness of the diagnosis and the ominous prognosis previously made, were one unmindful of the remissions so characteristic of this disease. In the following February I was again called to see the patient. She was greatly prostrated and the characteristic yellow-hued pallor was prominent. The mucous surfaces were blanched, conjunctivæ icteric, lids puffy. Her stomach was rebellious. She had no pain, her sight was dim, hearing dull, the abdomen sensitive. Venous murmurs were present. The urine was as previously noted. Blood examination showed 520,000 red corpuscles, but it was so watery that the hemoglobin (approximately 15 to 20 per cent.) could not be readily estimated. Irregularity of red corpuscles was very marked; nucleated red cells, normoblasts and megaloblasts (few of the latter) present. Temperature 101 F., pulse weak and of low tension. The stool was examined for possible parasites, but with negative results. All symptoms became more severe, and the patient died in coma one week later. No autopsy.

The existence of these two fatal cases of anemia, considered to have been more than a mere coincidence, roused this family to a state of great apprehension lest other members become similarly attacked. So when about two years later a third sister developed marked pallor, and after four years a fourth also showed unmistakable evidence of anemia, their fears seemed well grounded. In both of these patients, however, evidence favored anemia of the secondary type (associated with melancholia in one, and in the other with menorrhagia), and they are now and have remained in good health.

While the occurrence of the two cases above detailed was not without interest and, because of the unusualness of the facts, may have deserved reporting, I was loath to place them on record at the time because of the suspicious development of secondary anemia in the two other sisters, it being well established that secondary anemia may eventuate in the primary form. I was wholly unprepared, then, for the blow that came from another and wholly unexpected quarter. A brother, the only member of the family with whom I had had a long acquaintance, next fell victim to the disease.

Case 3.—Primary anemia. *Summary.*—Male, aged 42. Aplastic form of pernicious anemia. Blood-findings less severe than in Cases 1 and 2. Spastic-paralytic nervous type (system sclerosis of spinal cord).

Of the three cases this one presents the most interesting (because atypical) form of the disease. Whereas Cases 1 and 2 were quite characteristic in their symptoms, development, course, and blood-findings, of the type in which the disease usually manifests itself, and therefore afforded no diagnostic difficulty, this one presented some problems. The blood-findings of the usual form of pernicious anemia are—within certain limitations—rather characteristic, but the less common and so-called "aplastic" type of the disease offers difficulties of proper classification. The aplastic type, as described by Ehrlich, is characterized by the reduced red blood-count and hemoglobin, but the evidence of cellular regeneration, the nucleated red cells, is absent; in other words, the bone-marrow is aplastic. Therefore, in the absence of the natural reparative process, the rapidly fatal issue of these cases is to be foreseen (80 per cent. of the patients die within three months. Edwards).

History.—In addition to representing the aplastic type, this patient also developed in most marked form the spinal sclerotic nervous symptoms occasionally encountered in pernicious anemia. I had had many years' previous acquaintance with this patient, though no professional relations. He consulted me in March, 1909, complaining of a host of nervous disturbances which he referred to an injury (he was struck on the head and badly beaten by a burglar) sustained one year previously. Syphilis was denied. He had apparently recovered completely from the injuries and their temporary effects, and was well until about November, 1908. At this time he first experienced cramp-like sensations, and numbness and paresthesias in hands, legs, feet and on the abdomen; complained of failing memory and physical weakness, of great fatigue, and of loss of sexual power; no pains in arms and legs. He called attention to his anemic condition. There was much mental depression and loss of ambition.

Examination.—Tactile sense was found normal, but some incoordination of upper and lower extremities was present. Buttoning coat and trousers was accomplished with much difficulty. Knee-jerks were active, ankle-clonus absent, cremaster and abdomen reflexes normal; no Babinski. Gait was of the spastic-paretic type, with ataxic incoordination; the legs were held rather rigid and yet were flung about quite uncontrollably, resembling the reeling of an intoxicated person, and requiring support—at first of a cane, and later that of two persons. Pupils were small and reacted sluggishly to light and accommodation. In general the symptoms resembled a spastic paraplegia, *with marked incoordination*, greatly overshadowing in prominence and intensity the underlying primary anemia itself.[3]

Course of Disease.—I ventured the diagnosis of primary anemia at this time, although this opinion was refused by the family and rejected by another physician. The patient seemed to improve somewhat during the summer; some of his nervous symptoms were less noticeable, others became more pronounced, and the anemia was less prominent. He returned under observation in August with decidedly accentuated nervous disturbances: the mental and physical symptoms had advanced with great rapidity, a fear lest he were syphilitic overcame him, and delusions of persecution became prominent. He saw imaginary foes on mischief intent, lurking on all sides and dogging his footsteps. He became suspicious of food lest it be poisoned, and fought taking drugs for the same reason. Several maniacal outbursts were noted later, and once the nurse described an attack she thought was a convulsion. (This was probably an epileptic seizure.) The incoordination increased and the paresis became paralysis; he became bedridden, refused food, and suffered urinary incontinence and great constipation. The development of bed-sores was unavoidable, and thus, greatly emaciated, and in a condition of asthenia, he died, seven months after having come under my observation.

The blood examination, on his first visit in March, was as follows: red corpuscles, 1,500,000; hemoglobin, 55 per cent.; color-index, 1.7; poikilocytes present but of small degree; no nucleated red cells; heart, lungs and kidneys were normal and remained so throughout the disease. The various erythrocyte counts ranged from 1,500,000 to 3,000,000, the hemoglobin estimate from 45 per cent. to 60 per cent.; color-index always above normal: 1 to 1.7. The pallor of skin and mucous surfaces noted at his first visit became less evident during the early period of general improvement (there was one brief remission with betterment of symptoms and blood-findings), but later were markedly intensified. The peculiar lemon-yellow skin-tint was present, but not of striking intensity.

The blood-findings were characteristic of the aplastic type of the disease: reduction in red cell count and hemoglobin, retention of the high ratio of color to number of cells, and a striking absence of evidence of regeneration. In the many specimens searched, but a small number of nucleated red cells could be found.

It would be idle to speculate on the reason for the apparent staying of the progress of the anemia. The blood-picture, though fluctuating within narrow limits, did not undergo material change after the nervous manifestations became pronounced. This was strikingly illustrated in the repeated examinations made while the patient was bedridden, and during the many weeks of pronounced nervous disturbances, mental and physical. Death was traceable, not so much to the underlying pernicious anemia, as to the adynamia of the pronounced spinal sclerosis that developed in connection with and consequent on the anemia.

---

[3] Sclerosis of the posterior and lateral columns has been found in these nervous cases, and three groups are distinguished: (a) those in which the nerve symptoms appear late in the course of a case of obvious pernicious anemia; (b) those in which there are no nerve symptoms (except peripheral paresthesia) during life, but obvious sclerotic changes in the cord post mortem; (c) those in which the cord symptoms precede and overshadow the manifestations of anemia. This most interesting group of cases has been studied especially by James J. Putnam of Boston, Modern Clinical Medicine, p. 313.

The diagnosis of primary pernicious anemia cannot, I believe, be questioned in the three cases cited, and naturally, much alarm is felt lest there be a tendency to the development of the illness in other members of the family. Of the three remaining sisters, one is now, and has been, in perfect health; two have suffered, during the past six years, from recurring attacks of anemia of the secondary type.

Case 4.—Secondary anemia. The patient was first seen in October, 1904, after the death of Patients 1 and 2. She was then 46 years old. She had had numerous attacks of severe anemia, due to menorrhagia and metrorrhagia, but had always "made blood" rapidly. During my early acquaintance (two years) with this patient her pale and corpse-like complexion was very striking. Any severe loss by menstrual flow brought on an intense, bloodless hue. At one time examination showed a red count of 1,200,000, with 25 per cent. hemoglobin, with microscopic characteristics not those of primary anemia. Improvement ensued: red count increased to 3,550,000, hemoglobin to 50 per cent. After 1906 this patient's improvement seemed quite firmly established, and she appeared to enjoy perfect health. A daughter, an only child, had been chlorotic, but was, at the time of this report, in good health.

Case 5.—Secondary anemia. Sister of Patients 1 to 4. The patient consulted me in 1908. She was suffering from melancholia, was pallid, but well nourished. Examination showed a red count of 3,700,000; hemoglobin, 45 per cent.; blood of the secondary anemia type. Her appearance suggested the possibility of less favorable blood-findings. Marked general improvement set in during one month's observation, and she has since remained in perfect health, mental and physical.

Case 6.—Primary anemia. *Summary.*—Mrs. G. C., aged 34. Cousin on paternal side of Patients 1 to 5. Two remissions. Lowest erythrocyte count 300,000. Death due to terminal infection—probably endocarditis.

History.—The father of this patient died of arteriosclerosis at the age of 65; the mother of gastric cancer, aged 50. There are two healthy children, 12 and 5 years of age respectively. This patient was first seen in March, 1910. Until May of the previous year she had always been in good health. At this time she had a severe bronchitis, and with it there existed a mild degree of anemia. She recovered good health and vigor during the following summer, which was spent in the country. She continued well during the winter, but in spring the cough returned, and with it weakness and pallor. Because of the recurring cough she consulted a throat specialist who disregarded entirely the pronounced and rapidly increasing anemia, great weakness and dyspnea, and instituted local treatments for a period of three weeks.

Examination.—On her first visit to me at this time there was no escape from a ready recognition of the seriousness of the illness: her lemon-hued pallor was extreme, the weakness pronounced, and every exertion was attended with dyspnea. She suffered from an irritating cough. At the left base crackling râles were found, without evidence of consolidation. The heart sounds were normal at the apex, and accentuated at the base. Albumin and hyaline casts were present. Abdominal examination was negative. Pupils, reflexes and tactile sensation were normal. A hasty blood examination gave the following result: hemoglobin, 30 per cent.; reds, 1,850,000; marked poikilocytosis; no erythroblasts.

Course of Disease.—One week later jaundice was noted, liver normal, spleen two finger-breadths below costal margin, evening temperature rise to 100 F., pulse 100 to 110. The patient was growing steadily weaker and paler, and suffered from diarrheic stools. A differential leukocyte count made at this time resulted as follows: polynuclears, 63; large mononuclears, 7; small mononuclears, 18; transitionals, 6; eosinophils, 3; myelocytes, 3. A diagnosis of primary pernicious anemia was concurred in by an observer of large experience. All symptoms advanced progressively and quickly, and ten days later the following notation was made: heart dilated, presystolic and systolic murmurs at apex, precordial systolic thrill, liver enlarged and tender, spleen three finger-breadths below costal margin (larger than previously noted); jaundice, stupor and delirium; red corpuscles, 625,000; white, 13,000. Numerous examinations were made during the three weeks' period of observation, the erythrocytes at one time shortly before death recording as low as 300,000, with hemoglobin approximately 20 per cent., though accuracy was hardly possible. Normoblasts were present in small number. poikilocytosis very pronounced. The terminal infection in this patient closely resembled that reported in Case 1.

Case 7.—Brother of father of Patients 1 to 5; also paternal uncle of Patient 6. This patient did not come under my personal observation, but I have every reason to feel satisfied that the diagnosis of pernicious anemia made in his case is substantiated by the facts as related to me by a competent observer. Blood examinations showed conditions characteristic of the disease.

There has thus been sketched a family scourge that, so far as I have been able to ascertain, is unique in the annals of medical literature. It will be noted that all these cases have developed on the paternal side. I have no explanation to offer, can find absolutely no foundation for even speculative conjecture as to the transmissibility of a hemolytic substance. Patients 1, 2, 3 and 6 were married and had individual households; their consorts have remained uninfluenced, and their children, numbering five, are in perfect health. No parasites were found in Cases 2, 3 and 6 (stool of Patient 1 was not examined).

There can be no question that pernicious anemia is on the increase. The disease was considered one of comparative rarity a decade ago, and its greater frequency cannot entirely be due to its more frequent and ready recognition. Possibly the observation I have here made may suggest research in other channels. Certainly there can be no suspicion that coincidence could, by any mere chance, have played a curious prank in the development of these fatal cases of essential anemia.

I would summarize in the following deductions the study of this series of cases:

1. The clinical history and blood-findings permit of no doubt that five of these patients (two brothers and one sister, a paternal cousin, and a paternal uncle) suffered from primary pernicious anemia.
2. The weight of evidence which the two cases of secondary anemia add is not to be wholly ignored, because anemia of the secondary type has frequently been known to be a precursor of the primary form.
3. Hunter's theory, so strongly defended by him, that septic conditions in the mouth—stomatitis, glossitis, etc.—are the etiologic factors in this disease, sheds no light on this series of family anemias. (No such mouth condition existed in any of the cases.)
4. The possibility, as here shown, of its being a family disease, and the knowledge that the disease is on the increase—not only relative, but absolute—suggest an as yet unrecognized source of hemolysis that is showing increased general activity, and is uninfluenced by environment or station.

141 Wisconsin Street.

Excretion of Hexamethylenamin into the Eye.—Experiments show that urotropin (hexamethylenamin) is excreted into the anterior chamber of the eye in about three hours after ingestion, reaches its maximum excretion in about seven hours, and is excreted in great quantities after repeated paracentesis. The excretion of urotropin into the anterior chamber of the eye is remarkably increased by the use of a mydriatic locally. Urotropin in the aqueous humor in the concentration in which it occurs in the anterior chamber does not inhibit the growth of virulent organisms in the test tube.—H. S. Gradle, in *Ophthalmic Record.*

WHAT SHOULD BE THE ATTITUDE OF THE STATE TOWARD THE PRACTICE OF MEDICINE?

M. L. HARRIS, M.D.
CHICAGO

As a result of the efforts of physicians, every state has enacted so-called medical practice acts, the ostensible purpose of which is to protect the people against ignorance and incompetence on the part of those who treat the sick. The majority of these medical practice acts were passed, or, at least revised—some of them more than once—during the past ten years, which is not only an indication of the unusual activity in these matters, but also means that the whole subject is in a very unsettled and unsatisfactory condition.

Before discussing the principle underlying these medical practice acts I wish to state that I firmly believe that they were passed with the sole purpose of protecting the health of the people, and that the thousands of physicians who labored earnestly and honestly for the passage of these bills were actuated only by the purest and most unselfish motives; yet I never could make myself believe that the principle underlying them is right. I believe that, with one or two exceptions, these medical practice acts are fundamentally wrong in principle. I do not mean to convey the idea that they are illegal or unconstitutional; it would be the height of folly for me to express such an opinion in the face of numerous supreme court decisions, including five by the Supreme Court of the United States, that the acts are constitutional. But the mere fact that a law is constitutional is no evidence that it is right.

For a law to be right it must fulfil other demands than those expressed in or denied by constitutions. It must have inherent that which makes for the betterment of the people and this betterment, when possible, should be of a lasting or even progressive nature rather than some apparent or temporary good.

RESTRICTIVE PRINCIPLE

The present medical practice acts are all based on the restrictive principle. The central idea is to restrict the practice of medicine by licensing those who are permitted to engage in it, no person to be given a license who does not possess certain qualifications. Were such an act justly and honestly administered, so that the license to practice carried with it the evidence of the possession by the holder thereof of the high qualifications mentioned, then it would seem that the people would receive that degree of protection against ignorance and incompetence on the part of the physician which it is the intention and purpose of the act to give. But, notwithstanding the fact that the restrictive principle or licensing plan is in operation in practically every state in the Union, the intent of the law—i. e., the protection of the people—has never been realized. The reasons are not difficult to discern.

In the first place, while practically all medical practice acts are based on the restrictive principle, it will be found on reading them that not one holds strictly to the principle. While the profession has been able to convince the people that, for their own protection, it was necessary to license the physician, it could not make the people believe that it was necessary for them to surrender the right to think and the right to seek health by whatsoever route they saw fit, even though that route was thought by some to be unsound and unsafe. As a result we find the statutes of many states encumbered with acts prohibiting the practice of medicine by anyone except a duly qualified and licensed physician and at the same time containing so many exemptions as to rob the acts of all their power for good.

Is it possible to conceive of a more farcical monstrosity in the shape of a medical practice act than that found in the Code of Massachusetts which exempts osteopaths, pharmacists, clairvoyants, persons practicing hypnotism, magnetic healing, mind-cure, massage, Christian science or the cosmopathic method of healing? Such an act provides that the honest, educated physician must possess all kinds of qualifications, which have taken him years to acquire, and then be examined and licensed before he can practice, while any fake, fad, or fraud may be practiced by anybody without restriction. Scientific knowledge and an honest endeavor are dangerous and must be restrained by license!

Twenty-five states, or a little more than one-half, exempt from the provisions of the law some of the following: Medical students practicing under licensed physicians, interns in hospitals, dentists, pharmacists, oculists, chiropodists, midwives, clairvoyants, hypnotists, magnetic healers, masseurs, osteopaths, sellers of patent or proprietary medicines, persons practicing Christian Science, Swedish movement, mind cure, cosmopathic method, any drugless method of healing or any method not using poisonous drugs. Have any of the present-day fads or fakes escaped recognition? Yes, chiropractic and faith-healing, but they are already knocking at the door, as bills exempting them have just been introduced in Nebraska, the District of Columbia, Minnesota, Iowa and Oklahoma, and similar ones undoubtedly will soon be bobbing up all over the country, for those interested in securing such legislation work with a system worthy of a better purpose.

Another reason why the restrictive or licensing plan has failed to accomplish its purpose is found in the interpretation which many judges and courts have given the acts. The point which the courts usually have been called on to decide is whether a certain method of treating the sick constitutes the practice of medicine. It hardly seems possible that a body of educated, intelligent persons accustomed to interpret the meaning of words as applied to the concrete facts of life would confuse a single means to an end with all that is involved in the concept, practice of medicine, yet we frequently find courts defining the practice of medicine to be the giving of drugs, than which there is nothing more absurd or ridiculous, as such a definition is held to mean that a person who is diagnosing and treating the ailments of human beings is not practicing medicine unless he is giving drugs.

An excellent illustration of the inconsistency of courts in their interpretation of what constitutes the practice of medicine is found in the decisions regarding osteopathy. No person who is at all familiar with the facts will deny for a minute that the osteopath is treating human beings afflicted with all kinds of ailments, yet in fifteen states we find that either by statutory enactment or by decision of the courts the osteopath is held to be a practitioner of medicine, while in twenty states, by decision of courts of equal jurisdiction, he is declared not to be a practitioner of medicine. How can we explain such diametrically opposite opinions of so many equally high courts in so many different states in the Union? It is not contended for a moment that any of the eminent jurists composing the several courts which have passed on this question were influenced by anything except their best judgment in the matter, but an analysis of the law and of the decisions in the various states shows this curious psychologic fact. In those states in which the law makes some provision for osteopathy most of the decisions have been that the osteopath is practicing medicine, while almost all of the court decisions to the effect that osteopathy is not the practice of medicine have been in those states which make no provision in the law for osteopathy. As a result, the effect of these contradictory decisions is practically the same, inasmuch as it makes it possible for the osteopath to practice in either case.

Can it be possible that the eminent jurists who have decided in so many states that the osteopath is not practicing medicine, and is therefore exempt from the provisions of the medical practice acts, were influenced in their decisions, consciously or unconsciously, by that higher moral law, which says that no person shall be deprived of the right to think and to act as his mind dictates, provided he do no harm? Let us at least hope that such was the case.

Notwithstanding the constant watchful efforts of the profession, osteopathy has gained recognition by one means or another in a large majority of the states in the Union, as has also Christian Science, "optometry" and many other fads, and we may be sure that any other pathy or ism which has a sufficient following will gain recognition in the same way. It may be that this is but a pessimistic view of the subject, but I am satisfied that anyone who has watched the development of, and the changes which have taken place in, the various medical practice acts, and has seen anything of the manner in which the said acts are enforced, must be convinced that they fail to accomplish that for which they were enacted.

It must be admitted, then, that the restrictive or licensing plan of regulating the practice of medicine is a failure, because there are too many exemptions, because too many isms and pathies have gained recognition, and because there have been too many adverse decisions by judges and courts; hence it does not protect the people against ignorance and incompetence as was the intention.

ANOTHER POINT OF VIEW

Let us now disregard the question of the success or failure of the restrictive plan and consider the subject from an entirely different viewpoint.

If it were possible to enact a law which prohibited any one from practicing medicine who has not been licensed so to do, and which prohibited the licensing of any one who was not shown by an examination that he is qualified, would it be a good plan? I believe not, for I think such a law fundamentally wrong in principle. To say that no person shall treat the sick except those licensed by the state on a qualification basis, is but another way of the state saying to the individual: "You may employ no person or no means to relieve yourself of your sufferings and your afflictions except those designated by the state." Can you see any great difference in principle between this dictum and one of not many years ago to the effect that one must believe certain things and worship in accordance with a definite custom?

Has the state the moral right to deprive the individual of the liberty of thought and action in the one case any more than in the other? I believe that it has not, and therein lies the fundamental defect in the principle underlying the restrictive plan of regulating the practice of medicine. It deprives the individual of the liberty of thought and action to his own detriment, and without compensating good to the state.

By this I do not wish to be understood as saying that there should be no difference in the attitude which the state should assume toward the individual's religious beliefs and toward his care of his health. On the contrary, I think there should be a most marked difference. In the one case we are dealing with a spiritual or an immaterial belief which affects only the individual himself, while in the other we are dealing with the material physical health of the individual, which concerns not only himself, but frequently those who are dependent on him, as well as all those who may come in contact with him.

Furthermore, a large percentage of those who are unable to earn a livelihood by reason of temporary or permanent ill health become a charge either directly or indirectly on the public and, therefore, it is not simply a product of the fancy, but a stern reality, that places the health of the people as the greatest asset of the state and ill health or disease as a positive liability which must be met. These facts then, concerning which much more might be said, place on the state an imperative duty to conserve and safeguard the health of the people. In attempting to carry out this duty we find that the state has enacted certain laws which, on analysis, indicate that the legislators who framed them were either unfamiliar with, or else disregarded, the principles and laws of sociology and psychology, and this too frequently is found to be the case. The attention of legislators is directed to the existence of an evil and pressure is brought to bear on them to correct it. A law is passed which often leads to greater evils than the one which it attempts to correct. As an illustration of this point attention may be directed to some of the medical practice acts already cited.

The evils of quackery, fraud, charlatanism, etc., in the treatment of the sick are called to the attention of the legislators. A law is at once passed to do away with the evil by licensing physicians to practice medicine and prohibiting from practicing all those who are not licensed. This law at the same time gives legal recognition to all forms of quackery and charlatanism, the very evils which it was intended to correct, by specifically exempting them from the provisions of the act.

Take another instance. A state passes a rigid restrictive measure which deprives the individual of the liberty of thought and says to him, "You may employ only a person of a certain class to treat you if you are ill." In other words, the state presumes to do the thinking for the individual, which is not only detrimental to an enlightened and progressive mind, but leads to that state of opposition on the part of the people shown by the inability to convict offenders, even in the fact of established guilt, and thus creates a contempt for the law which is destructive of good government.

In this connection permit me to quote from an editorial in the February, 1911, number of the *California State Journal of Medicine* on the enforcement of the California law:

> "It is almost impossible to obtain a verdict, no matter how conclusive the evidence may be, for practicing without a license if the case is tried in a police court. In San Francisco recently a number of such cases were tried and a verdict of acquittal given when the evidence was absolutely conclusive."

And yet California prides herself on her *medical practice acts*. Such a law also undoubtedly leads some judges so to interpret it as to quite nullify its effect. These are all greater evils from a sociologic standpoint than the ones sought to be corrected.

The law in a matter of this kind should not be dictatorial to the extent of depriving the individual of the right to think for himself, for when the state assumes to do the thinking for the people progress in that direction is at an end. In framing laws of this nature legislators should constantly bear in mind, not only the evils which are to be remedied, but also the fact that the people as a whole are progressively advancing in an evolutionary sense toward higher levels. The law, therefore, when possible, should attempt to aid rather than hinder this progressive evolutionary development of the people.

It is not contended that the laws can all be made to meet the contingencies of future progress without change, but what I claim is that the laws as expressed by the people should be based on the natural laws of evolution as found exemplified in the individual and in society.

THE CORRECT ATTITUDE

With these facts in mind, what then should be the attitude of the state toward the practice of medicine in its broadest sense?

It will be admitted, I think, by all that the preservation of the health of those who are well and the proper care and treatment of those who are ill and afflicted is a work of the utmost importance and one which should be encouraged and fostered in every legitimate way possible. From this standpoint, then, there can be no reason why those who are qualified should be hampered or restricted in the work in any way whatsoever.

Granting that the licensing of physicians is not a revenue measure, the only sound reasons why the state should interfere in the matter are, first, to guard the individual against fraud, ignorance and incompetence on the part of the physician; and second, to protect the people against the sick individual. The first reason, then, is guidance of the people, the second, protection of the people. These two duties, guidance and protection, however, are separate and distinct functions.

It will be granted that all phenomena in Nature follow definite fixed laws and that these laws apply to animate as well as to inanimate matter. This means that the phenomena of life as manifested in health and disease are all the result of natural laws. From this it becomes self-evident that any person who makes a business of treating the sick in any manner whatsoever should have as thorough a knowledge as possible of those laws which govern the living in health and disease.

It is a well-recognized fact that these laws are abstruse and obscure and so numerous that it requires years of close, hard study for one to become familiar with them; and in order that one may keep abreast with the rapid progress of knowledge it is necessary for one to devote his entire time and energies to the subject. This makes it impossible for those engaged in other vocations in life to hope ever to become familiar enough with most of these laws to make use of them without counsel and advice, and, unfortunately, practically every person at one time or another must seek the advice of some one trained and skilled in this branch of knowledge.

These are the facts which place on the state the imperative duty of guiding him who is in search of such advice to one who is qualified to give it. This the state should do through a suitable board of competent men, whose duty it should be to inquire carefully into the qualifications of all those who may properly come before it; and it should have the power to designate in some unmistakable manner those who are found to possess the necessary qualifications. This designation, be it qualified physician, certified physician or what not, should be used by the person receiving it on his card, his sign, in his office or wherever desired, so that all who may wish to consult him may know at a glance that he is a person qualified to treat the sick.

Of course it should be made unlawful under heavy penalty for any person not authorized to do so to apply to himself in any way whatsoever the term of qualification, or any similar term, with the intent to deceive. Furthermore, in order to make it impossible for anyone to err unknowingly in the matter, every other person who attempts to treat or advise the sick or ailing in any manner whatsoever should be compelled to announce on his own card and in his office or place of business, in a conspicuous manner, the fact that he or she is not a qualified physician. In this manner the state fulfils perfectly its duty of guiding the individual, for it makes it impossible for any person who is seeking a qualified advisor on matters of health unknowingly to go astray. By this method it will be seen that all the perplexing questions of isms and pathies are wiped out at once, as it permits anyone to practice in any way one chooses and it likewise permits any person who thinks that his ailments can be relieved only by the prayers of a Christian Scientist or the rubbings of an osteopath or masseur, to act according to the dictates of his conscience.

Were I to stop here it *might be said on first thought* that the method would permit all kinds of quackery and charlatanism to run riot throughout the land; but it will be remembered that the duties of the state in this connection were said to be two, namely, guidance and protection, and protection must supplement guidance. Protection of the people in health matters falls under the general supervision of the department of health and under those laws which govern the individual's responsibility to other individuals and to society as a whole.

None but qualified physicians should be eligible to any medical position in the public health service or in any public or charitable institution under the control of the state or any of its municipalities. As all contagious diseases are a menace to the public and as most of them should be reported to the proper health officers, no unqualified person should be permitted to assume the medical care of such cases.

All parents, guardians and institutions having minors under their care or control should be obliged to furnish them, in case they are sick or injured and require it, with qualified medical attention.

No death certificate should be accepted by the authorities unless signed by a qualified physician, etc. In this manner the state will be able to carry out its duty of protection. It protects the people in general and those individuals in particular who rightly come under its jurisdiction, yet it does not deprive the adult of the right to think and to act for himself so long as he thereby does no harm to others.

In conclusion, permit me to say that I believe the restrictive or licensing plan of regulating the practice of medicine is fundamentally wrong in principle, in that it makes the state dictatorial in a matter of personal rights, which is best left to the thinking individual. It makes conviction of offenders by a jury at times impossible, even in the face of established guilt, because the law is against the conscience of the people. For the same reason, perhaps, it leads judges and courts practically to nullify the law by the interpretations which they give to its provisions. It is evident that the restrictive plan has not the unqualified approval of legislators, otherwise we would not find the law so frequently emasculated by the numerous exemptions found therein.

The law is constantly bombarded by all kinds of pathies, such as osteopathy, optometry, chiropractic, etc., and with increasing success, which shows that the people believe (and justly too) that they have the right to try anything they want to obtain relief from their ailments. On the other hand, the plan but very briefly outlined here is free from all of these objections. It protects the individual in search of a qualified physician by making it impossible for him unknowingly to go astray. It protects the people and all dependents against ignorance and incompetence, so far as it is possible for the law to act; and last, but not least, it is in perfect accord with the evolutionary development of the individual and of society.

THE SUBSEQUENT HEALTH OF CHILDREN WHO DRANK MILK CONTAINING TUBERCLE BACILLI *

ALFRED F. HESS, M.D.
NEW YORK

Three years have passed since I undertook an investigation of the milk sold in New York City, to determine primarily to what extent the ordinary milk sold in cans, which forms the major part of the milk-supply of the city, was contaminated by tubercle bacilli. This study included also an inquiry into the types of these bacilli, whether bovine or human, and a preliminary investigation into the welfare of the children who were so unfortunate as to drink this milk in its raw state. This report was read[1] in 1908, and was afterward published in The Journal.[2] It showed that of the 107 specimens of milk tested on guinea-pigs, 16 per cent. contained virulent tubercle bacilli. Details of the report will be found in the original paper. In order to elucidate what follows, however, it seems necessary to review briefly some of the facts as to the method pursued in the investigation. To obtain the specimens I accompanied the municipal milk inspector on his regular tour, and asked the dealer in each store (they were situated mainly in the tenement-house district) whether he had small children, and whether the children drank the milk in the raw state. Unless he told me that this was the case, I did not take a sample for the test. Of the samples which were found to contain tubercle bacilli, ten were from dealers whose children had been exposed in this way to infection. There were eighteen children in all; nine of these were 2 years of age or under, and one 5 years of age. The preliminary study of the health of these children was not conclusive, and the data are summarized in Table 1. This table shows that the health of the children did not seem to have suffered from their exposure, except possibly in one instance, in which a cervical adenitis had developed. In this case, however, no search for tubercle bacilli was made when the gland was incised, and accordingly the nature of the infection was doubtful. The child was poorly nourished and gave a positive tuberculin reaction, as did several of the other children.

Since 1907-1908, a period of over three years, I have continued to supervise the health of these eighteen children; visiting them in their homes about every three months and watching carefully for the development of any sign of tuberculosis. This has been attended with some difficulty, as the people of the tenements in New York move frequently, and seem by habit to leave no address. Sixteen children, however, have been closely followed, one for two years, and only one was completely lost sight of. I realize that the number of children on whose condition I can report is not large, and that a period of more than three years might be of advantage in judging of the development of tuberculous infection; but I make this report now as I may be unable to follow these cases any longer, and as I believe that the results are of interest from several points of view.

I may add that the only similar report has been a recent one from the Imperial Health Commission of Germany,[3] which investigated the health of 151 children who drank raw milk coming from cows with tuberculosis of the udder. Two of these children between the ages of 1 and 2 years developed cervical gland tuberculosis, from which a bovine type of bacillus was cultivated. Some other children showed signs suspicious of tuberculosis. The two tuberculous children drank the infected milk for long periods, but, except for the glandular infection, were in good health one and one-half and two years later, respectively.

This report is open to one criticism, which cannot be made in regard to the investigation which I report. Tubercle bacilli were not demonstrated in the milk. A clinical diagnosis of tuberculosis of the udder of the cow was considered the equivalent of finding tubercle bacilli in the milk. Now although this is generally the case, nevertheless it has been found that the milk from cows with tuberculosis of the udder does not at all times contain tubercle bacilli; and, in the second place, udder tuberculosis is frequently confounded with non-specific infections. It is therefore quite possible that some of these children did not drink milk containing tubercle bacilli.

Of the seventeen cases which I have followed, in only one has tuberculosis developed. The other children present the picture of the average tenement-house child, most of them poorly nourished, undeveloped, but free from any active tuberculosis. Four have passed through an attack of measles, one has had scarlet fever, two have suffered from pneumonia without inducing tuberculosis. The child who did develop tuberculosis was 2 years of age when she was given the milk containing tubercle bacilli. This milk was of very poor quality, for milk from the same source was repeatedly found by me to contain virulent tubercle bacilli. In Table 1 this child is described as being poorly nourished, having had cervical adenitis 4 months previously, showing a positive von Pirquet reaction, but with a family history negative as regards tuberculosis. I was out of the city when the cervical adenitis developed and the gland was incised, and accordingly missed the opportunity of obtaining some of the pus or tissue for bacteriologic study. Last winter, however, a cervical gland enlarged near the site of incision of the former gland, and in due course showed fluctuation and was incised. This time I obtained some of the pus, which showed no tubercle bacilli in smear preparations, even with the aid of the alkalin sodium hypochlorite ("antiformin") method, but produced tuberculosis in both guinea-pigs into which it was

inoculated. Without going into detail as to the method of isolating and differentiating tubercle bacilli, for such description is no longer necessary, I may state that the strain proved to be typically bovine, as judged by its cultural characteristics and virulence for rabbits.

There is no means of knowing whether this infection was due solely to drinking in tubercle bacilli on this particular day, or whether this child had been exposed similarly on previous days. We may be certain, however, that infection did not result from a subsequent milk exposure, as the parents were warned of the danger, and henceforth boiled the milk for the children. In this connection it should be noted that it is by no means inconsequential whether a definite amount of tubercle bacilli is ingested in one dose or in repeated doses. The chance of infection is less when the bacilli are taken in at one occasion than when approximately the same number is ingested in divided doses. I was able to demonstrate this fact conclusively by a simple experiment on guinea-pigs. It had been ascertained that 2 mg. of a certain bovine culture of tubercle bacilli did not produce tuberculosis in guinea-pigs when given to them suspended in milk. Of ten pigs which had received this amount, none developed tuberculosis. The animals were fed by means of a medicine-dropper, and the suspension was so calculated that each pig received about ten drops of milk. In a second series, ten pigs, weighing between 250 and 350 gm., were now given less than 2 mg. (which may be called the subinfectious dose of this culture), but instead of being fed to them at one time, this amount was divided into ten, twenty, thirty, and thirty-five doses, given on as many days. Two of the pigs died prematurely; the other eight were killed after three months and were examined carefully for tuberculosis (Table 2). From the table it will be seen that several of the animals developed tuberculosis. In other words, a quantity of tubercle bacilli which may be insufficient to cause infection when given at one time, may have this power when given frequently in small amounts. Repeated exposure to infection at short intervals tends to lower an animal's resistance; a law which probably applies to other bacteria besides tubercle bacilli.

TABLE 1.—DATA CONCERNING CHILDREN WHO DRANK MILK CONTAINING TUBERCLE BACILLI

Milk Dealer.	No. of Children.	Age. Years.	Conjunctival Test.	Condition One Year Later.

8	35	0.05	=	1.75	Tb.

* Ten guinea-pigs, used as a control experiment, received 2 mg. of this culture in one dose, and failed to develop tuberculosis.

This same phenomenon may well have played a part in the infection of the child who developed tuberculous adenitis. The milk which she drank was found to contain tubercle bacilli oftener than any other which I examined, and it is probable that she consumed tubercle bacilli on many occasions, and that the summation of exposures resulted in infection.

From a clinical point of view there are some points in this case worthy of passing mention: The bovine bacilli remained latent in the cervical glands for two years and caused merely a slight enlargement; the tonsils were not markedly hypertrophied, nor were adenoids present; and, finally, the general condition of the child decidedly improved during the course of the past year and the cutaneous tuberculin reaction became much more pronounced.

Without exaggerating the importance of the bovine bacillus in the etiology of tuberculous lesions, I feel that we must acknowledge that its rôle is not insignificant in childhood. The case of milk infection which I report is not of great interest as an isolated instance of infection by this type of bacillus. Since the report of the British Tuberculosis Commission and the more recent report of Park and Krumwiede[4] showing the frequent occurrence of bovine infection among children, it is unnecessary to adduce further evidence as to the incidence of this type of tuberculous infection. It was rather my purpose to show by means of a definite case that, although a group of children can frequently, without apparent harm, drink milk containing tubercle bacilli, nevertheless such milk can be shown at times to incite infection.

I cannot close without some words as to the means of safeguarding the children against infection by the bovine tubercle bacillus. I feel that I can repeat what I wrote in my previous paper: "Milk not coming from tuberculin-tested cows should be pasteurized or brought to a boil." In substance this is the position recently taken by the New York City Board of Health as regards milk for infants. I should like to add to what I said previously that I believe some care should be taken also in regard to butter, which, it is needless to say, is frequently permeated with virulent tubercle bacilli. Butter is fed without concern to almost all children over one year of age. It is a strange anomaly that we should fear the tubercle bacillus in milk, but urge our children to take butter, which has been found so often to harbor the same bacillus. I believe that there is danger in feeding butter to young children, and cannot see why those who demand milk from tuberculin-tested cows do not make the same demand for the butter for the children. It should also be made possible to purchase a certified or a pasteurized butter; that is to say, a safe butter. It is not necessary for me to pursue this subject further. I wish merely to call attention to the matter, at the same time adding that the idea is not quixotic, but has been carried out in Denmark and other countries for many years. The dealers in certified milk frequently have some of their produce left unsold, which, with profit, could be made into small prints of "certified butter."

---

[4] Park, William H., and Krumwiede, C.: The Relative Importance of the Bovine and Human Types of Tubercle Bacilli in the Different Forms of Human Tuberculosis, Jour. Med. Research, 1910, xxiii, 185.

This subject seems to me to be timely for the consideration of the certified-milk committees which have been so efficient throughout the United States.

SUMMARY

Of eighteen children who drank milk in which tubercle bacilli were demonstrated, all but one remained free from active tuberculosis during a period of supervision of three years; this one developed tuberculosis of the cervical glands, from which a bacillus of the bovine type was cultivated.

From animal experiments we can conclude that the chance of infection through milk depends not only on the number of bacilli ingested, but also on the frequency of exposure to small infections. For a quantity of bacilli which was insufficient to produce tuberculosis in guinea-pigs when given in one dose, suspended in milk, was able to incite tuberculosis when fed in twenty-five to thirty doses on as many days.

Tubercle bacilli in milk are a menace to the health of young children. Tubercle bacilli in butter are likewise a menace; therefore, a safe butter, whether pasteurized or certified, should be provided for their use.

THE SURGICAL RELATIONSHIP BETWEEN UTERINE FIBROIDS AND LOSS OF CARDIAC COMPENSATION [*]

R. L. PAYNE, JR., M.D.
NORFOLK, VA.

Since Hofmeier, in 1885, first called attention to the presence of heart lesions associated with fibroids there has been some little interest shown, as evidenced by the careful study by a few writers of individual and collected cases and reports thereof. From a careful study of the literature and a thorough analysis of personal cases I am forced to conclude that there is a definite relation between fibromyomata and the associated condition of lost cardiac compensation. The term "lost cardiac compensation" is rather indefinite, and in the beginning I wish to explain my acceptance of the term as meaning, the symptoms resulting from a loss of normal cardiovascular tone; whether this be due to morbid, organic or functional changes matters not a bit, for even in a severe anemia we have present all the signs, both subjective and objective, of lost cardiac compensation, and functional heart lesions do often give rise to just as many distressing symptoms as those found associated with organic changes.

Up to this time all that has been written on this interesting subject gives evidence on one side of the question, namely, that there are often associated with fibromyomata the symptoms of cardiovascular changes. I propose to discuss another side of the question, namely, that the eradication of the uterine fibroids not only benefits the patient locally, but in some cases results in a more or less complete dissipation of the cardiovascular symptoms. A few brief reports of cases will clearly show my meaning.

REPORT OF CASES

Case 1.—*Patient.*—Mrs. S., aged 35, mother of one child 4 years old, suffered with retroversion. I performed a round-ligament suspension operation on her in March, 1907. The uterus at that time was normal in size. Six months later she consulted me for extreme shortness of breath and swelling of the ankles. The uterus at this time was normal in size and position. The dyspnea continued for the next three months and became so distressing that the patient had to stop her work in a cotton factory.

Examination.—Physical examination showed cyanosis of lips and finger-nails, swelling of the ankles, a weak, rapid pulse of the mitral type, a weak apex beat and a distinct murmur over the mitral area. About this time the menstrual periods became prolonged, with excessive flow, and in the next two months became as frequent as every two weeks. None of the usual remedies gave any relief and I concluded that the metrorrhagia was a result of lost cardiac compensation and the coincident passive congestion. As a matter of precaution, I decided to make a pelvic examination and, to my surprise, found two subperitoneal fibroids about the size of walnuts and also a small submucous fibroid. The cardiac symptoms were steadily growing worse and, being unable to lie down, the patient slept propped on pillows or in a chair.

Operation.—The metrorrhagia continued and the demands to stop it became so urgent that an operation was decided on as a choice between two evils. Ether was used and until its powerful stimulating effects began to tell on the heart and vessels the anesthetist had to keep the patient's head and shoulders well elevated on pillows. I hurriedly did a supravaginal hysterectomy, and when the patient was returned to bed her heart action and respiration were so good that I advised placing her flat on her back with no pillow under the shoulders.

Postoperative History.—Recovery from the anesthetic was normal and from that time on the patient had no trouble in retaining the recumbent posture, whereas for two months past she had suffered intensely from dyspnea. The pulse slowed considerably; all the ankle swelling and shortness of breath disappeared completely and at the end of six weeks the patient was able to resume her work. The murmur over the mitral area still persisted, but the symptoms of lost cardiac compensation were completely dissipated and at the time of making this report this patient was doing daily work and was in very good health.

Up to this time I had been totally ignorant of any relation between uterine fibroids and associated cardiovascular symptoms, and it is easy to imagine my astonishment at the results obtained in this case. I then began to study my gynecologic cases with the result that, in the succeeding three years, four more cases of similar type fell into my care. One of the patients was a very intelligent white woman, 43 years old, who had a fibroid the size of a grapefruit, growing symmetrically from the fundus. In this instance there was no hemorrhage, and a rapid, excitable pulse and dyspnea were the only cardiac signs. Removal of the growth resulted in a complete relief of all symptoms.

The next two cases were in colored women, one 40 years old, the other 30, both of whom had no hemorrhages, but there was present a cardiac murmur, rapid feeble pulse and dyspnea, which became distressing on the slightest exertion. These patients found relief of all cardiovascular symptoms in a period of four to six weeks after removal of the fibroids.

My fifth case was the most interesting of all.

Case 5.—*Patient.*—D. T., colored, aged 35, was brought to me by her physician, who said she was suffering from a large ovarian cyst.

Examination.—I found a typical hepatic facies, extreme shortness of breath, which did not permit the patient to assume the recumbent posture for even a few minutes; a very small pulse, beating 130 times per minute; heart-sounds so weak that I could not be sure of the presence of murmurs; limbs swollen to threefold their normal size and an immensely distended abdomen which rested on the patient's thighs. Palpation, percussion and vaginal examination disclosed nothing but fluid and I reluctantly had to discredit the physician's diagnosis of ovarian cyst, and expressed the opinion that the whole condition was one of lost cardiac compensation. The physician then said that he had most assuredly felt some hard tumors in the pelvis about three years back and had not seen the patient since until a few days previously. We then decided to tap the abdominal cavity, and after the slow withdrawal of 14 gallons of ascitic fluid a number of subperitoneal fibroids, all confluent and about the size of small apples, were easily palpable. The patient went into collapse at the finish of the tapping and I thought would surely die, but she managed to pull herself together.

---

[*] Chairman's Address before the Section on Gynecology, at the meeting of Tri-State Medical Association at Raleigh, N. C., Feb. 22, 1911

Operation.—I then decided to try to stimulate her heart to better work before attempting an operation, and waited four days, during which time there was considerable reaccumulation of ascitic fluid. This patient had not slept lying flat for three months and at the operation the anesthesia was well established before we were able to place her flat on the operating table. Under ether her pulse picked up tremendously and after a supravaginal hysterectomy she was placed in bed in the recumbent position.

Postoperative History.—Reaction was normal, but during the first three days the patient's head and shoulders were kept in a partially elevated position to facilitate easy respiration. After this time she had no trouble in breathing. Her convalescence was eventful, in that the swelling of the limbs entirely disappeared and though there was a slight reaccumulation of ascitic fluid during the first week, there was a total absence at the end of a month and the patient left the hospital with a comparatively good heart action. A communication from the patient's physician one year later informed me that she still maintained her cardiac compensation.

I do not make any claim to originality in reporting these cases, but the results obtained are facts which I think worthy of recording. Too little attention has been paid to the presence of cardiovascular symptoms associated with fibromyomata, and though the cases reported are few in number yet they furnish sufficient evidence to show a definite relation between fibroids and disturbed heart action, and further, that an ablation of the new growths has a decidedly beneficial effect on the symptoms of lost cardiac compensation.

There is sufficient evidence recorded to prove that there are both functional and organic cardiovascular changes associated with fibromyomata, but very little evidence to prove that these changes are due directly to the new growth. The cases herein recorded would lend support to the latter hypothesis.

PREVIOUS LITERATURE ON THE SUBJECT

Following Hofmeier's exposition, the next article of moment on this subject came from Fenwick[1] in 1888, in which he recorded twenty-two cases of large cystic tumors, each patient showing on post-mortem examination fatty degeneration of the myocardium. Fenwick thought that the cardiovascular symptoms and organic changes were due to obstruction of the circulation. Later data would discredit this theory.

In 1898 Strassman and Lehman[2] reported a series of seventy-one cases of fibromyomata in which 48.8 per cent. of the patients had definite symptoms of cardiovascular disease. The signs were both objective and subjective and the observations in each case were made by a careful internist. These authors record one very important fact, namely, that in many of the cases the fibroids were very small. To this fact I shall refer later. In 1904 Fleck[3] reported 325 cases of uterine fibroids in 34.6 per cent. of which there were heart changes giving definite symptoms. In eleven of these cases post-mortem examination showed fatty degeneration and infiltration, and brown atrophy in seven.

The year 1905 brought forth several excellent articles by Noble, Winter, Baldy and Boldt, the last two authors handling the subject in a very fair and careful manner. Winter[4] reported 266 cases of fibromyomata, in 30 per cent. of which there were murmurs and definite heart symptoms. Dilatation and hypertrophy were found in 6 per cent. and organic valvular disease in 1 per cent. Boldt[5] records seventy-nine cases of uterine fibroids, in thirty-seven of which there were cardiovascular disturbances. Baldy[6] records 366 cases, in which series there were thirteen sudden deaths. These he attributed to the associated cardiac degenerations. The two latter writers review the subject from the standpoint of the gravity of cardiovascular changes associated with fibromyomata and give evidence to establish the fact that the cardiac disturbances are often of so serious a nature as to produce sudden death immediately or some time after operation. Webster[7] reports 210 cases with cardiovascular symptoms in 25 per cent. Since the recognition of my first case in the summer of 1907 I have had a series of fifty-five cases of uterine fibroids, in five of which there were definite signs, both objective and subjective, of cardiovascular disturbances.

With these recorded facts before us, our interest would naturally turn to the cause of them; and it is here that much is still left for the pathologist, internist and surgeon to explain. Winter believes that all the symptoms of lost cardiac compensation are due entirely to anemia and that little degeneration of the myocardium and no permanent heart lesions are present. This anemia he ascribes to the hemorrhage and coincident malnutrition accompanying fibromyomata and supports this theory by saying that hemorrhage occurs in two-thirds of all cases. The relation of anemia, kidney insufficiency and cardiac weakness is well known, but statistics will not support the anemia hypothesis. The bulk of authorities record hemorrhage in about one-third of all cases and in Fleck's series 133 patients had no hemorrhage, yet heart symptoms were present in 34.6 per cent. In the five cases reported by me, hemorrhage was present in only one and it is a well-recognized fact that in carcinoma of the uterus hemorrhage and malnutrition are present in about 90 per cent. of the cases; yet these signs produce no such symptoms as those found associated with fibromyomata. Brasin called attention to this fact as early as 1893.

Strassman and Lehman think that the cardiac symptoms are due to the myocardial and vessel changes. This would hardly hold true except in well-advanced cases, because the cardiac symptoms were more or less completely dissipated in my cases after removal of the fibroids, which would have been most improbable if definite organic lesions were present. Veit believes the cardiac symptoms are reflex through the nervous system, and in 1900 he called attention to the frequency of asthmatic attacks in young women with small tumors and thought this asthma was due to fibroids.

Percepied[8] calls attention to dyspnea of utero-ovarian origin and cites a number of instances which he considers reflex from the genital organs; 40 per cent. of his patients suffering with asthma developed attacks near the menstrual period, and this would lend support to the ovarian theory. From a careful study of Percepied's cases the greater evidence would support an hysterical basis of explanation, rather than that the dyspnea was due to some internal secretion from the ovary. Fenwick's theory of obstruction to the circulation is worthless because Veit, Fleck, Strassman and Lehman, Fehling, Hennig and others report cardiac symptoms associated with small growths, and in my cases only one patient had a growth large enough to produce any circulatory obstruction. On the other hand, Fenwick's cases would point to the ovary.

[8] Ann. Soc. méd-chir. de Liége, 1910, xlix, 126.

I am disposed to believe that the cardiac symptoms are due to the products of uterine growth on the heart-muscle or heart-ganglia—some internal secretion directly the product of uterine hyperplasia.

This is supported by the following facts:

1. Hemorrhage, as a causative factor, was present in only one of five cases.
2. In Case 1, there is conclusive evidence that the cardiac symptoms developed before there were any signs referable to the uterine growth, this being still small when discovered. Both Veit and Strassman and Lehman cite cases in which cardiac symptoms developed before any signs referable to the pelvis, and this fact alone would discredit the idea of the causative factor being a nervous reflex or organic changes in the heart and vessels; on the other hand, it would lend color to the probable presence of some product of uterine growth acting on the cardiovascular system.
3. Removal of the fibromyomata resulted in a more or less complete relief of all cardiac symptoms; partial relief came too quickly to have resulted from any regeneration of organic changes.

Carl Hennig[9] records two cases of cardiovascular disturbance in which the patients were cured by the removal of associated fibromyomata, and one case in which the patient was relieved after the menopause when the fibroid decreased in size.

Fehling[10] says that in the presence of fibroids, the first symptoms of cardiovascular disturbance should be an indication for operation; and it is interesting to record here a case reported by Carl Wettergreen[11] of Basedow's disease and a submucous myoma beginning at the same time. Removal of the myoma dissipated the exophthalmos and tachycardia.

CONCLUSIONS

1. In a large percentage of cases of uterine fibroids there are present symptoms of cardiovascular disturbance.
2. The size of the growth has no relation to the severity of the cardiac disturbance; symptoms have been apparent while the growth was still small.
3. In some cases of lost cardiac compensation associated with fibromyomata, the symptoms are materially benefited by removal of the growths.
4. In some cases the cardiac disturbances are of so severe a type as to result in sudden death following operation.
5. The first signs of cardiovascular disturbance associated with uterine fibroids should be an indication for immediate operation, and the watchwords in these cases should be: (a) rapid surgical technic; (b) careful hemostasis; (c) as little handling of the viscera as possible, and (d) the greatest caution against overtaxing the heart during postoperative treatment.

AN IMPROVED DIFFERENTIAL ELASTIC TISSUE STAIN

F. H. VERHOEFF, A.M., M.D.
Pathologist and Assistant Ophthalmic Surgeon, Massachusetts Charitable Eye and Ear Infirmary; Instructor in Ophthalmic Pathology, Harvard University
BOSTON

Three years ago I described[1] a new method for staining elastic tissue that had given me more satisfactory results than any of those usually employed. More extended experience with this method has shown that the best results are to be obtained only when the staining fluid is freshly prepared. Not only is this a source of inconvenience, but it entails considerable expense, owing to the large amount of hematoxylin required. After much experimentation, in which it seemed to me I tried every conceivable modification, including the substitution of almost all the metals for iron, I finally devised, about a year ago, the method here described.

This method has the advantages over the previous one, that the staining fluid is made up from stock solutions, that about one-ninth as much hematoxylin is required, and that when carefully carried out, precipitates may be avoided and differentiation of the sections is not necessary. The latter advantage I have found especially great in staining serial celloidin sections prepared in the manner described by me elsewhere.[2] The staining fluid may also be used in my method for staining myelin sheaths,[1] if double the amount of ferric chlorid solution is added, and the sections are allowed to stain six hours or longer.[3]

A stock solution is prepared as follows:

Hematoxylin crystals (Grübler)	0.15 gm.
Absolute alcohol	25 c.c.
Dissolve by aid of heat, then add 5 per cent. aqueous *solution of ammonium hydrate*	1 drop
Allow to stand five minutes (longer does no harm), then add Lugol's solution (iodin, 2; potassium iodid, 4; water, 100)	22 c.c.

Filter, and allow to stand twenty-four hours (in corked bottle), after which the solution works well for three months. Solutions one year old stain elastic tissue well, but slightly discolor connective tissue.

For use, add to each cubic centimeter required of the above stock solution, one drop of a 7 per cent. stock solution of ferric chlorid in absolute alcohol. Sections are carried from alcohol into the staining fluid, where they remain one to three hours. In the case of Zenker's fixation, sections may be allowed to remain in the fluid over night, but will then certainly require differentiation. The staining receptacle should be covered to prevent evaporation. For celloidin sections, 2 c.c. of the staining fluid are ordinarily sufficient, and a small bottle makes a convenient receptacle.

Wash sections in water a minute or two, examine under the microscope, and if thought desirable, differentiate for a few seconds in a 1 per cent. aqueous solution of ferric chlorid, roughly prepared from the above alcoholic solution.

Wash in water. Counterstain in a 0.2 per cent. solution of water-soluble eosin in 80 per cent. alcohol.

Alcohol, oil, balsam.

[2] See Note on Technic in paper on Obstruction of the Central Retinal Vein, Archives of Ophthalmology, 1907, xxxvi, 32.

[3] I have recently found that the myelin sheath method is further improved by differentiating the sections for one to two hours in a 10 per cent. aqueous solution of phosphomolybdic acid, instead of in the ferric chlorid solution previously recommended.

y this method elastic tissue is stained black, while ective tissue, fibroglia, myoglia, neuroglia, myelin, fibrin, take the eosin stain. Nuclei take the hema- ylin stain with an intensity depending on the dura- n of the staining. Fixation in Zenker's fluid is pre- red, but other fixatives give good results. Mercurial ecipitates if removable are removed by the staining uid.

To prevent precipitates it is important to avoid the addition of water to the staining fluid. The measuring graduate and the staining receptacle even if dry, should be washed out with a little alcohol previous to use. It is also necessary to have a nice adjustment of the proportion of ferric chlorid. If too little ferric chlorid is added, the elastic tissue will fail to stain: too much produces precipitates and overstaining. It is possible that different samples of hematoxylin may require a slightly different proportion of ferric chlorid, but this may easily be determined by trial. For ordinary purposes, however, none of these precautions is necessary, since precipitates may be readily removed in the differentiating process.

THE PARTHENOGENETIC DEVELOPMENT OF OVA IN THE MAMMALIAN OVARY AND THE ORIGIN OF OVARIAN TERATOMATA AND CHORIO-EPITHELIOMATA *

LEO LOEB, M.D.
ST. LOUIS

Some years ago, I described[1] peculiar structures that are found in the ovaries of guinea-pigs, and expressed the opinion that they originated in ovarian follicles. Soon after I had published my observations, certain considerations suggested to me that these structures owe their origin to parthenogenetically developing ova.

Inasmuch as at that time I had not yet seen early stages of the structures referred to, I was unable to regard this hypothesis as sufficiently well founded to warrant publication. I continued my investigations in this direction, however, and recently I succeeded in finding in two animals the desired early stages. They must be interpreted as embryos developing parthenogenetically within the ovary of the pinea-pig. We see in each case a chorionic vesicle with trophoblast, and plasmodia and syncytia penetrating into the neighboring tissue. There is also a structure present which is probably to be interpreted as the neural tube.

Aberrant blastomeres cannot be seen in the ovaries of guinea-pigs and, inasmuch as the embryonic structures, described in my former communication, are relatively frequent, occurring in approximately 10 per cent. of all guinea-pigs below the age of six months, and, furthermore, inasmuch as they are situated in the cortex of the ovaries at a place where follicles lie normally and are found within follicle-like cavities, they can be derived only from ova developing parthenogenetically. Fertilization through spermatozoa can be excluded, inasmuch as the history of some of these animals is known to us and precludes such an interpretation. It is very probable that the parthenogenetic development sets in soon after ovulation, the altered conditions in the ovaries at that time (variations in blood-pressure, in intrafollicular pressure, changes in oxygen supply) supplying the necessary stimulus. This interpretation agrees well with my former observations[2] concerning the parallelism existing between the first segmentations taking place in ova within the ovary and certain stages of atresia of follicles. At the time of ovulation an almost general degeneration of the Graafian follicles sets in as I have shown[3] recently. It is also of interest to note that frequently the changes described in this communication are multiple, several ova undergoing parthenogenetic development in the same ovary.

It may be concluded, therefore, that in at least 10 per cent. of all guinea-pigs parthenogenetic development of ova within the ovary starts at some period of the life of the animal. The later stages of these developing embryos bear some resemblance to chorio-epitheliomata. During ovulation, these structures are occasionally injured by hemorrhages and they are ultimately invaded and supplanted by the neighboring connective tissue.

These observations demonstrate that chorio-epitheliomata and teratoid tumors that are found in the ovaries are not derived from misplaced blastomeres, as Bonnet and Marchand believed, but that the older view is correct according to which at least the teratoid tumors of the ovary are derived from parthenogenetically developed ova, an opinion which I, also, expressed on previous occasions.

A RARE MANIFESTATION OF EMPYEMA NECESSITATIS *

JULIUS H. COMROE, A.M., M.D.
Physician to York Hospital
YORK, PA.

A. H., aged 16 months, female, whose family history and past personal history were negative, on Dec. 15, 1910, developed a "cold" which was associated with a stubborn cough, chilliness, and vomiting. On the following day there was added marked dyspnea, anorexia and all the physical signs of a lobar pneumonia involving the entire right side, anteriorly and posteriorly. The temperature was 103 F., the respirations 60 and the pulse 170. December 17, the left lung became similarly involved with the exception of that portion underlying the last three ribs posteriorly. In the early morning of December 18, the child suddenly developed alarming symptoms of collapse, with marked cyanosis, exaggerated dyspnea, rapid running pulse and prostration. The patient was in a moribund condition. Physical examination revealed a marked dilatation of the heart. After several hours of continuous stimulation by mouth, skin and rectum, in which large doses of strychnin, strophanthin, and nitroglycerin were employed, the cardiac condition was restored.

The patient ran a typical course of a very severe type of pneumonia, until on December 29, when an apparently slow lysis was interrupted by a rising of the pulse, respiration and temperature. The respiration reached a maximum of 110, the pulse 180, and the temperature 104.5 F. Physical examination revealed complete flatness over the entire right chest posteriorly, with absence of breath sounds and tactile fremitus. There was marked Skodaic resonance from the fourth to the seventh rib, and from the right sternal margin to the mammary line anteriorly. Exploratory puncture in the seventh interspace, midaxillary line, December 29, brought the expected pus. Microscopic examination of this pus showed the presence chiefly of streptococci, with, also, numerous pneumococci and staphylococci. We were dealing, therefore, with a streptococcic pneumonia. Repeated aspirations demonstrated

* Reported before the York County Medical Society, Feb. 2, 1911.

the existence of saccular collections of pus. January 2. the patient suddenly developed a most violent attack of coughing, which could in no manner be checked, and which alarmed the attending nurses. At 10 a. m., she "expectorated" about one-half ounce of pus, during one of these coughing spells, and the diagnosis of rupture of the empyema into the bronchi was at once made. Sedatives were administered in many forms and the cough was somewhat checked. The patient was somewhat nauseated. At 11:20, a gush of four ounces of pus from the mouth followed an attack of cough, and at 12:05, one-half pint of pus was forced through the mouth with a similar attack. At 1.10, two more ounces of pus were expectorated. Thus in a space of three hours, about one pint of pus was expectorated. With careful stimulation the patient improved. January 3, with parental consent, the patient was anesthetized by Dr. Treible, with ether, nitrous oxid and oxygen, given conjointly, and one inch of the seventh rib, in the midaxillary line, was resected. After breaking numerous bands of adhesions which divided the pleural cavity into many pockets, over one quart of pus was liberated. Tube drainage was inserted, followed by the injection of bismuth paste (Beck), and the use of gauze drainage. The patient made an uninterrupted recovery, and is now in Florida enjoying good health.

Generally speaking, the term "empyema necessitatis" refers to an empyema in which pus can make a spontaneous escape (Dorland). Some authors limit the term to the condition in which the pus makes its escape through the chest wall. Empyema may rupture into the esophagus; into the bronchi; through the chest wall: through the diaphragm into the peritoneal cavity; into the pericardium, etc. This spontaneous rupture is a very rare manifestation of empyema complicating pneumonia, especially in an empyema of short duration.

Kerley reports one somewhat similar case of rupture into the bronchi, in a well-nourished boy of three years. Holt states that of nineteen cases of empyema in children, reports of which were collected by Schmidt. "in which a spontaneous discharge of pus occurred either externally or through a bronchus, there were seventeen deaths and two recoveries."

Therapeutics

CAFFEIN

Description.—*Caffeina*, genitive *caffeinæ* (methyltheobromin, or trimethylxanthin) is an alkaloid obtained from the dried seeds of coffee (*Caffea arabica*), and from the dried leaves of tea. When it is obtained from the latter source the alkaloid is called *thein*. Caffein, though the most important constituent of coffee, is a feeble basic principle, and occurs not only in *Caffea arabica* and *Thea sinensis* (or *chinensis*), but also is found in other plants as gaurana, theobroma, cola nut. and maté. Coffee, named from Coffee, a province of Nareá, in Africa, grows on a medium sized tree, which is native of Arabia and parts of Africa, but grows in all tropical countries. Coffee was first introduced into Europe in 1554, and into England in 1640.

Tea is a native of Asia, but grows in other warm climates. Green tea leaves are purer than the black, as they are more carefully collected and dried, the black being dried in heaps.

Coffee may be adulterated with various seeds or beans made of clay or kaolin, while tea may be colored artificially.

Caffein was discovered by Runge in coffee in 1820. Thein was discovered by Oudry in tea in 1827. Caffein and thein are identical, and can be obtained from infusions of coffee or tea by chemical reaction. Caffein (trimethylxanthin) can be prepared synthetically from xanthin.

There are various varieties of coffee, the most important of which in the order of their purity are: first, Mocha; second, Java; third, Rio; fourth, Liberian; but all can be injured by too much heat in roasting. Good coffee yields about 1 per cent. of caffein, while maté or Paraguay tea and Chinese tea yield a little more. Cola nuts yield 2 per cent. of caffein, and gaurana 5 per cent. Much of the caffein in the shops is made from the sweepings of tea warehouses, or from tea which is so damaged as to be unfit for a beverage. The volatile oil or empyreumatic oils of coffee have, in hot decoctions, some aromatic action. A cup of coffee may contain a half teaspoonful of such oils.

Caffein occurs as white, long, flexible, silvery-appearing crystals, generally in masses, odorless, not deliquescent, bitter, and soluble in considerable water or alcohol. The dose of caffein is from 0.05 to 0.10 gram (or from 1 to 2½ grains), but it is best used in the form of the citrated caffein.

Local Action.—There is no external action from caffein, though cold strong infusions of tea are mildly sedative to mucous membranes, perhaps due to the gentle astringent action of the tannic acid contained in the tea. Strong solutions of tea or coffee are mildly irritant to the stomach.

Systemic Action.—Caffein as such is rapidly absorbed, having no local action. As a strong decoction of black coffee it may act as a stomachic or bitter tonic, and may, therefore, stimulate the outpour of the gastric juice. Coffee is stimulant to peristalsis by its aromatics, and therefore increases the secretion of the mucous membrane of the intestines and slightly stimulates the bile secretion, hence coffee is a mild laxative. Decoctions of tea if strong, on the other hand, rather retard digestion, and on account of the tannic acid tend to constipate. A cup of good coffee made with half an ounce of ground beans contains from 0.10 to 0.20 gram of caffein and some substances that act as volatile oils. A cup of good tea made with 100 grains of leaves contains about 2 grains of caffein, though bulk for bulk of tea leaves and coffee beans, the tea contains the more caffein. Green tea contains some volatile oils, black tea very little. Both contain about 7 per cent. of tannic acid, which is extracted slowly, hence the viciousness of prolonged steeping. The volatile oil in the after-dinner cup of black coffee is probably a slight stimulant to digestion, while the hot decoction causes a slight carminative action from the volatile oils. Coffee also slightly stimulates the salivary secretion.

Circulatory System.—Caffein causes the heart, in animals, to beat more rapidly by acting either on the heart muscle or on the terminations of the accelerator nerves. This rapidity seems to be due to a shortening of the diastole and the force of the muscular contraction is increased. This acceleration may be due to stimulation of the irritable muscle in the lower parts of the heart. When caffein is administered to man by the stomach, the heart is generally slowed, owing to the action on the inhibitory center in the medulla. A strong action of caffein lessens the strength of the auricular contraction and later of the ventricular, and soon there is a lessening of the amount of dilatation during diastole. As poisoning progresses the diastole grows shorter, and the ventricles and auricles contract irregularly, and as above stated, without complete relaxation. Very large doses cause very irregular cardiac action, and later permanent contraction or rigor as in skeletal muscles. After death the heart may be found in diastole.

The vasomotor centers in the medulla are stimulated by this drug, causing contraction of the arterioles, and this is the principal cause of the rise of blood-pressure, as the output of blood from the more rapidly contracting heart is not much increased. The muscular coat of the walls of the arterioles is also somewhat stimulated to contraction. The blood becomes somewhat depleted of its water by the strong action of caffein on the kidneys, but it gets its supply again from the tissues.

Nervous System.—Here caffein acts not unlike strychnin, but acts more on the brain. The cerebral cortex is stimulated and the mental functions improve, in fact, it is our best cerebral stimulant. Under its action thoughts are rapid, there is wakefulness and the patient is alert; if the dose is too large, there may be rapid reasoning, but with not so accurate judgment as usual. Whenever fatigue or mental inertia are in evidence, caffein is a temporary cure of the condition, but at the expense of the organism. In other words, it calls forth the reserve power.

Under an over-dose there are convulsions and increased reflex irritability, and any irritation may cause contraction of all the muscles.

Coffee and tea increase the rapidity of mental impressions and the development of thought, but the perfecting or carrying out of these intellectual conceptions may be retarded. Large doses of caffein, or a coffee or tea habit will impair mental activity by increasing the general nervous and reflex irritability. Caffein in over-dose often causes headache, and there may be delirium, tremor, and restlessness, though a tolerance is acquired in those accustomed to its use, but there is always in large doses increased nervous irritability. It is a respiratory stimulant by its action on the medullary center.

The senses are all made more acute under the action of caffein, especially the sense of touch. There is a slight increased temperature during the action of caffein, probably from the increased muscular activity, and also due to the increased oxidation caused by caffein. It has a mild aphrodisiac action, probably due to spinal stimulation.

Muscular System.—A small amount of caffein is a muscle restorative and will increase the strength and temporary endurance of muscles, and more work and longer work can be done without fatigue or sleep under the influence of caffein, probably due to peripheral stimulation of the muscles. However, the system will always pay for this sight draft on its reserve energy. A large amount of caffein, however, is a muscle poison, and injected directly into a muscle it causes a peculiar stiffening or rigor. Coffee and tea, or caffein, increase tissue waste, though they call out the reserve muscle and nerve forces, due to nervous stimulation. The urea and the carbon dioxid output are increased. The chief effects of tea and coffee are due to the caffein and to nothing else.

Action on Secretion.—Caffein is an active diuretic, unless too large doses are used, when a vasomotor contraction is caused by over-stimulation and this contraction affects the blood-vessels of the kidney. Theobromin is, therefore, a better diuretic than caffein, as it causes no contraction of the blood-vessels. Caffein causes some increase of the solids of the urine and the nitrogen is increased, but the increase is mostly of the watery part. Sodium chlorid is the most increased, while uric acid is not at all increased. Hence, caffein probably acts on all the secreting parts of the kidneys; rarely, it may cause a mild glycosuria. The blood depleted of its water gets it either from the tissues or from any edema or infusion that may be present, or demands it from the stomach and intestines.

Action of a Therapeutic Dose or the Primary Physiologic Action.—Caffein increases the tone of the blood-vessels, increases the rate of respiration, stimulates the cerebral functions, increases muscular tone and power, diminishes fatigue, increases the excretion of urine, especially the watery part, and hence raises the specific gravity of the blood, which will then get more water where it can find it. It is excreted by the kidneys and appears in the urine partly as trimethylxanthin or caffein, partly as dimethylxanthin and partly monomethylxanthin, or xanthin.

Toxic Symptoms.—These are: rapid heart, cardiac oppression, due to its irregular contractions, irregular pulse; paleness of the face; restlessness, nervousness; increased reflex irritability, insomnia; rarely delirium and convulsions, and a diminished amount of urine due to vasomotor over-stimulation.

Treatment of Poisoning.—As a chemical antidote for whatever caffein may be in the stomach, tannic acid should be administered in solution or in suspension. As a physiologic antidote to spasmodic contraction of the blood-vessels, nitroglycerin should be given hypodermatically. As cerebrospinal sedatives, chloral and bromids may be given, unless the heart is too weak for such treatment, in which case morphin should be administered hypodermatically. Morphin will quiet the nervous system, but will not stop the action of caffein on the heart, hence nitroglycerin should be frequently repeated. Hot foot-baths may dilate the vessels and relieve some of the tension on the heart. Hot fomentations over the kidneys may aid these to more rapidly excrete the drug.

Therapeutic Uses.—The indications met by this drug are: (1) as a circulatory stimulant; (2) as a cerebral stimulant; (3) as a muscle stimulant; (4) as a diuretic; (5) as an antidote in poisoning.

1. Caffein is more than a cardiac stimulant in that it somewhat strengthens the heart and contracts the blood-vessels. As a cardiac stimulant caffein can be used at any time when such a stimulant is indicated. It acts quickly to tide over a period of cardiac depression, but is not so quick in its action in acute collapse as the reflex stimulation of a strong alcoholic preparation or the stimulation of ammonia. It is, however, a strong adjunct to the above and with strychnin makes an active respiratory and cardiac stimulant with no secondary depression. If there is in the cardiac weakness a good deal of nervous excitability and muscle restlessness, other cardiac stimulants and tonics should be chosen. The same is true when there is high vasomotor tension. As a cardiac stimulo-tonic caffein is indicated in prolonged fevers in place of much alcohol, and is good in typhoid fever in the form of a cup of black coffee given once or twice in the morning. It is best to avoid it in the afternoon on account of its tendency to cause wakefulness. As a cardiac stimulant in weakened heart action with poor cerebral circulation and mental sluggishness it is often efficient. Patients with good compensation in valvular disease should avoid the stimulation from much tea or coffee.

2. As a cerebral stimulant perhaps no drug equals caffein, not only in a person unused to its action, but in those accustomed to its use. While there is no intolerable and uncontrollable desire for caffein when it is

stopped by the ordinary coffee and tea drinker, still at the regular hours for tea and coffee stimulation, if it is omitted the majority of people miss greatly its effects. There is, however, such a condition as the caffein habit, and this habit is on the increase, and its seriousness should be explained to the laity. The hard brain workers at irregular hours, as editors, reporters, authors, and students just before examination, increase the number of hours which the brain will work well by frequent cups of coffee, learning that it is the best and most effectual stimulation that they can take, and often leading to no immediate noticeable secondary depression. As the coffee wakes up the brain, so to speak, it also stirs up the spinal cord and nervous and peripheral reflexes. The man after cerebral stimulation then smokes a good deal, which soothes the spinal irritation, and he then, having coffee plus tobacco can do an immense amount of brain work. If this is long kept up, sooner or later, depending on the individual endurance, a nervous, irritable condition supervenes with insomnia, anorexia, loss of weight, a tremulous tongue, with perhaps some trembling of the hands, with pale or yellowish skin due to disturbed liver function, and perhaps some kidney or bladder irritability, and we have a neurasthenic to treat. This means that all coffee and tea must be stopped and the patient given a mental rest, change of air and scene, and the institution of every legitimate means or subterfuge to produce sleep.

The chronic tea drinkers of this country are generally the kitchen girls and women who remain in the kitchen and in the house a great deal. The teapot is constantly on the stove and the strong stale brew full of tannic acid and bitter extractives is poured into the stomach at frequent intervals. Here we get not only the stimulation of the caffein, but the irritation of the tannin derivatives on the stomach mucous membrane, and tannin precipitates the peptones and albumins and soon causes dyspepsia. The sooner or later result is sleeplessness, an irritable fretty disposition, anorexia, nervous dyspepsia, or even gastritis, and constipation. Of course, the treatment is to stop the cause, treat the insomnia, dyspepsia and constipation, and give fresh air. Tea tasters show earlier than other individuals decay of the teeth. The above shows conclusively that children up to fifteen years should not drink coffee or tea regularly, and caffeinated soda fountain drinks should be prohibited.

Therapeutically, caffein as a cerebral stimulant can be used whenever a sudden demand for much brain work is required, as also in some mental morbid conditions, but all such use of caffein is purely tentative and symptomatic. The cause of the mental deterioration should be sought.

Caffein has been used as a substitute for alcohol in breaking off the alcohol habit.

As a respiratory stimulant caffein is indicated in conjunction with ammonia whenever respiration is failing. In headache, due to depression, sometimes in autointoxication from fermentation of the bowels, in some forms of neuralgia, and even rarely in migraine, caffein is efficient in changing the circulation and thus stopping the pain. Used for this purpose the dose should be 0.30 gram (5 grains), of the citrated caffein, and if there is no improvement in an hour, 0.15 gram (2½ grains) more may be given.

3. As a muscle stimulant, coffee and tea or caffein can be given to aid the endurance of any forced muscle work, especially valuable to soldiers on forced marches, but if such stimulation is frequently repeated the reaction is not satisfactory, in fact, depression will occur.

4. As a simple diuretic, caffein is rarely used, though its good auspices in this line are often sought in cardiac weakness with edema, but cardiac edema is better treated by digitalis unless there is some contra-indication to the latter and its congeners. In renal or hepatic dropsies it may be of some value, but other diuretics are better, if in fact a diuretic is indicated at all. As a diuretic, theobromin is better than caffein. To cause diuresis in general dropsy or in ascites, caffein must be pushed. This drug in ordinary dose does not irritate the kidneys or genitourinary organs, but in acute inflammation of these parts coffee and tea should be stopped.

5. As an antidote, caffein as such or as strong coffee is indicated in any depressant narcotic poisoning as by opium and its alkaloids, chloral, bromids, and other cerebral and spinal depressants. It is, as above stated, always a respiratory and circulatory stimulant. Enough caffein should be given to get decided improvement of the pulse. Strong coffee may be given by mouth or rectum, or caffein may be given hypodermatically. As an antidote to alkaloids in the stomach, tea containing a little tannic acid might be quickly used as a precipitant, but the precipitate soon dissolves in weak hydrochloric acid and in alcohol, hence alcohol should not be given at the same time that tannin in any form is used as a chemical antidote.

Contra-Indications.—The contra-indications to the use of caffein are palpitation, irritable heart, high blood-pressure, arteriosclerosis, cerebral or spinal inflammations or irritations, insomnia, neurasthenia, and acute genitourinary inflammation.

Official Preparations.—*Caffeina Citrata,* citrated caffein, is a white, bitter, sour, odorless powder, containing 50 per cent. of caffein, very soluble in water. The dose is from 0.10 to 0.20 gram (from 1½ to 3 grains), three times a day, or 0.30 gram (5 grains) used once.

Caffeina Citrata Effervescens, effervescing citrated caffein (caffeina, citric acid, sodium bicarbonate, and tartaric acid), dissolved in water makes a pleasant effervescing acid drink of caffein. Dose is a teaspoonful to a dessertspoonful, in a glass of water.

Non-Official Preparations.—*Caffein-Sodium Cinnamate* is a good preparation for hypodermatic use. The dose by the stomach is 0.20 gram (3 grains). Other non-official preparations are: *Caffein Hydrobromid, Caffein-Sodium Salicylate,* and *Caffein-Sodium Benzoate.*

A number of effervescing, non-official preparations containing caffein are found in the shops combined in so-called headache powders with acetanilid, antipyrin, phenacetin, or with one or more bromids. While these preparations are often elegant and efficient, the laity should be discouraged from their indiscriminate and, especially, frequently repeated use, as the bromo-caffein or other stimulo-sedative habit is easily acquired, and the outcome is a nervous heart and a neurotic and neurasthenic tendency. It should be distinctly remembered that it has been proved that the addition of caffein to any coal-tar product, whether acetanilid or some other, does not prevent the depression caused by the coal-tar synthetic, and in fact seems to add to its toxic effect.

Administration.—Caffein is absorbed rapidly and acts quickly, and its action lasts several hours. There is no cumulative effect. For continuous action it should be given three or four times in twenty-four hours. In acute indications it should be repeated every hour for a few doses. If it causes sleeplessness, the evening dose should be omitted. It is best given as caffeina citrata, dry, in capsules. For headache and for cerebral stimulation it is best given as strong black coffee or as tea, or as an effervescing caffein. Caffein may be used hypodermatically in dose of 0.05 gram (¾ of a grain), but it may cause a little pain, for a short time, at the point of introduction. Caffein-sodium benzoate is perhaps the best form for hypodermatic use. Caffein hydrobromid and caffein-sodium cinnamate are also used hypodermatically.

CONGENERS

THEOBROMIN

Theobroma (θεός, a god: βρωμα, food, "food of the Gods") or cacao, the native name (often called incorrectly cocoa) or chocolate, is made from the seeds of a large tree, *Theobroma cacao*, of Brazil and Central America. These seeds contain theobromin. Theobromin (dimethylxanthin) contains more nitrogen than caffein, and can be prepared synthetically from xanthin. Chocolate contains about 1 per cent. of theobromin, from a trace to 0.25 per cent. of caffein, and a large amount of fat (cacao butter from 30 to 50 per cent.), starch, albumin, and a little volatile oil. As all these latter constituents are assimilable, chocolate is a food. The seeds of the cacao tree, ground while warm with about an equal weight of sugar, and often flavored with 0.5 per cent. of cinnamon or other aromatic, makes the ordinary chocolate ready for solution in water or milk. Chocolate so prepared contains only a trace of caffein.

Theobromin does not stimulate the nervous system, hence it can be given when caffein, tea, or coffee are contra-indicated. Chocolate is rather rich and heavy for digestion in a weak condition of the stomach, hence chocolate is made for convalescents freed from oil and not sweetened. Theobromin has its greatest action on the kidneys, and is a pretty sure non-irritating diuretic. As above stated, it has no action on the nervous system, and but little action on the circulatory system.

Official Preparations.—Oleum Theobromatis, cacao-butter, is a fixed concrete oil expressed from the seeds of theobroma cacao. It is a yellowish-white solid, with a faint odor and taste of chocolate. It melts at the temperature of the body, and hence makes a splendid base for suppositories, one gram (15 grains), being the ordinary amount used for a rectal suppository. It makes a bland, soothing emollient application for irritations on the skin, for sun-burn, etc. It is sometimes adulterated with paraffin, wax and tallow.

Non-Official Preparations.—Theobromina is a crystalline bitter powder rather insoluble and but slowly absorbed. It is obtained from the seeds of theobroma cacao, and is also made synthetically. *Theobromina Sodio-Salicylas* (Diuretin) is a mixtures of equal parts of sodium theobromin and sodium salicylate, containing when pure 50 per cent. of theobromin, but ordinarily only 40 per cent. It is a white, odorless, salty powder, soluble in water. The dose is 1 gram (15 grains), given in aromatic solution or in capsules, generally three times a day, but it is often advisable to give it every three or four hours. It is largely used as a diuretic, as it acts on the renal epithelium without irritation, hence it can be used in both acute and chronic nephritis, and in cardiac and hepatic dropsy. In all ordinary doses there is no effect other than the diuretic. Rarely it produces nausea and headache, but this is probably due to impurities. Ex[illegible] [illegible]ng can be caused with symptoms [illegible] and dyspnea, increased temperature and some nervousness.

Theophyllin is another purin derivative found in tea, and is isomeric with theobromin (dimethylxanthin). It somewhat stimulates the nervous system, and is also a stimulant to the muscles. It is at times an active diuretic. It often causes severe irritation of the stomach, even when administered after meals.

It is a white, crystalline powder, almost insoluble in water, but in combination with sodium (theophyllin sodium) it is very soluble. The dose of either is 0.25 gram (4 grains). *Theocin* is a synthetic theophyllin.

GUARANA (BRAZILIAN COCOA)

Gaurana, gauranæ, is a dried brown paste made of the crushed seeds of *Paullinia sorbilis*, which is a climbing shrub, native of Brazil, named from Paullin, a German botanist living from 1643 to 1712; *sorbilis* is from *sorbere*, to suck or to drink. Gaurana is the name of a tribe of South American Indians. This drug contains from 4 to 5 per cent. of caffein theobromin, and about 26 per cent. of tannic acid, a trace of volatile oil, a resin, and a starch. The caffein of this drug has been called *gauranin*. The dose of gaurana is about 2 grams (30 grains). It acts like caffein and is stimulant to the nervous system. It is astringent on account of its tannic acid, and sooner or later upsets the appetite and causes dyspepsia. It is used for ordinary migraine headache, and in nervous and menstrual headaches, and also sometimes is used as a restorative after a drinking debauch. A gaurana habit can be formed.

Official Preparations.—Fluidextractum Gauranæ, fluid extract of gaurana. Dose, 5 c.c., or a teaspoonful.

KOLA

Cola-nut, *Cola acuminata*, is a large tree of Central Africa. The cola-nut contains about 2 per cent. of caffein, theobromin, starch, sugar, and a volatile oil. It acts like coffee and cocoa, and has been used as a food.

Kolanin is probably a mixture of caffein, theobromin and tannic acid.

The fluidextract of kola has been recommended as a muscle stimulant, as it has been proved that more physical labor can be done under the influence of kola when other food is withheld than without it. This is probably a caffein activity, in other words, depression must follow such stimulation.

Barium Sulphate and Serodiagnosis of Syphilis.—From the experiments of H. Noguchi and J. Bronfenbrenner, reported in the *Journal of Experimental Medicine*, it is clear that the absorption by barium sulphate is not directed in a selective manner to the antibodies. Barium sulphate has almost no anticomplementary action on guinea-pig serum. A light antihemolytic effect has been noticed when 1 c.c. of a 7 per cent. suspension of this salt was mixed with 0.05 c.c. of the complement. Barium sulphate removes both the anticomplementary substances and the syphilitic antibodies. The addition of one part of normal serum to one part of syphilitic serum reduced the removal of the antibodies to one-half of that obtained when no normal serum was added, and the addition of four parts of the normal serum to one part of syphilitic serum reduced the removal to about one-fifth. This indicated undoubtedly that the normal serum employed possessed the same affinity as the syphilitic antibodies for barium sulphate. The syphilitic antibodies are removed by barium sulphate (to which they seem to adhere), and the antibodies thus absorbed retain their activity. Several experiments were performed with antihuman amboceptor (rabbit), and the results show that the amboceptor is quite readily removed from the solution by barium sulphate absorption. The barium sulphate treated with the amboceptor solution retains the amboceptor and causes hemolysis when mixed with human corpuscles and guinea-pig complement. They conclude, therefore, that the barium sulphate absorption is to be recommended for the original method of Wassermann under certain conditions, but that it is unnecessary for the antihuman hemolytic system of Noguchi.

SATURDAY, MAY 6, 1911

THE ROCKEFELLER COMMISSION FOR THE ERADICATION OF HOOKWORM DISEASE

The whole rationale of lessening the evils of such social plagues as alcoholism, tuberculosis. hookworm infection and venereal disease lies obviously in educating the people up to the point of working out their own salvation. What has been accomplished by public exhibitions and lectures, by well-written popular articles in current magazines and periodicals and by direct personal appeal from physicians themselves, is far from insignificant, and what can be accomplished in a very short time is strikingly shown in two recent reports of the Rockefeller Sanitary Commission for the Eradication of Hookworm Disease. This commission was organized in October, 1909, and opened its offices in January, 1910. The work done to date is described in two reports, one by the administration secretary, Mr. Wickliffe Rose, the other by the scientific secretary, Dr. Charles W. Stiles, to whose important work the formation of such a commission was undoubtedly due. As stated by Mr. Rose, the task set for itself by the commission was to map out the geographic distribution of the infection. to effect a cure in existing cases and to remove the cause—in this case the pollution of soil by country privies and the use of human excreta as a "fertilizer."

Taking separate states as units for investigation. the commission cooperated with the various boards of health in appointing a director of sanitation in each state under whose direction a field force of sanitary inspectors was soon set to work. In addition, the public health laboratories of most of the southern states coöperated in the matter of making microscopic examinations of patients' stools. By combining the reports of the sanitary inspectors with the laboratory records used to check up their work, scattered hookworm infection has been demonstrated in all the southern states, including Tennessee and Kentucky, as also in Oklahoma, Nevada and California. Infection is particularly heavy in Virginia (ninety-one out of 100 counties), North Carolina (ninety-seven out of ninety-eight counties), Georgia (108 out of 145 counties), Alabama (sixty-three out of sixty-seven counties) and Mississippi (sixty-five out of seventy-six counties). In the mines of California it is reported so heavy as to be a matter of great economic moment. The degree of infection in foreign countries is also in process of investigation.

The task of treating present sufferers from the disease is threefold, involving, first, the cooperation of private practitioners by means of bulletins, letters and personal interviews; and second, the task of interesting the people in their own welfare through public demonstrations as object-lessons, medical examinations of school and factory children, laboratory diagnoses, free lectures and the dissemination of tracts; third, proper treatment of the infected poor by means of voluntary contributions and free treatment, as in Virginia and North Carolina, free dispensaries, as in Mississippi, or by the payment of a special bonus for each patient cured, as in Florida. The results of these various activities, as tabulated in Mr. Rose's report, are significant.

The most satisfactory cooperation of physicians in the general treatment of the disease was naturally secured in states having the greatest density of infection, as in North Carolina, Georgia or Virginia, and the same is true of the number of diagnoses made and the number of patients cured. The newspapers of nearly all the southern states were in thorough sympathy with the movement. It is interesting to note that the newspapers of Mississippi and North Carolina were at first humorously indifferent or resentfully antagonistic, but are now practically all of them in cordial cooperation.

During the first year of its administration the Rockefeller commission has spent over $47,000, while about $13,000 has been spent by the different southern states, making a total expenditure of a little over $60.000 for the eradication of hookworm infection in 1910. The best showing made by any state so far is that of Florida, for the reason that the board of health of that state is maintained by a mill fund of about $75,000 per annum. With such a sum at their disposal it was natural that the Florida public health authorities should have instituted a campaign against hookworm infection before the Rockefeller commission came into being. Since the organization of the commission they have cooperated with its work in a most admirable way, supporting themselves and spending nearly nine thousand dollars to this end. including a sum of $1,806 expended in payment for treatment of poor patients (a bonus of $3 for each patient successfully treated). During the year 1910. bacteriologic laboratories were established at Jacksonville. Tampa and Pensacola, and in these over 7.000 examinations for hookworm were made. A map investigation of the status of hookworm infection in Florida shows that "there is hardly a physician in the state not treating hookworm disease." and that even if the state board were to relinquish the work "the hookworm problem will now solve itself. so far as it can be solved."

The general effect of the propagandism of the Rockefeller Commission can best be ascertained by comparing Mr. Rose's statements in reference to Porto Rican and

American conditions. In Porto Rico, "the infection is severe, the people are sick, they know they are sick, and have learned that they can be cured." In the United States the infection is scattered and relatively light, and the people were at first not disposed to take it seriously; but as they gradually come to perceive its true significance "they come to look on it as they have been accustomed to look on tuberculosis, typhoid fever, or any other serious preventable disease."

The removal of the principal cause of hookworm infection by doing away with soil pollution is the main subject of Dr. Stiles' report. Very effective preventive measures are about to be introduced. Since Looss demonstrated that the hookworm usually enters the body through the skin, reaching the intestines by a devious route, all preventive measures have been concentrated on the surface of the body, in particular the hands and feet of those exposed to infection. The hookworm commonly thrives where it is warm and moist, as in mines, tunnels and cultivated fields. Pollution of the soil is perpetuated by those frankly suffering from hookworm disease, and also by "hookworm carriers," who, like the typhoid carriers, spread disease, although apparently free from it themselves.

Viability experiments, conducted under the direction of the Marine-Hospital Service, show that the mere burial of excreta does not prevent the eggs of the hookworm and other parasites from hatching. Such an expedient might prove an actual agent in infection, especially in the limestone regions. Sewerage is not practicable in the open country, and most of the surface privy systems in vogue are shown to be either faulty or unhygienic. Statistics show, moreover, that a large percentage of southern farms have no privies of any kind. The schools, churches and sawmills in the rural districts seldom have privies attached.

The crux of the hookworm question is, therefore, the contamination of the hands and feet of the country people by fecal matter, and the solution of the problem is in the sanitary privy. As Stiles puts it, "The privy is the great sanitary problem of the open country and the non-sewered village," and most of his recent experimental work, as set forth in his report, has been concentrated on this all-important point. During the past year Stiles, Lumsden and Roberts have devised a simple, inexpensive and practically odorless privy-trap which should assist materially in solving this problem. Improvements in this apparatus are now being made and models have been loaned out to different organizations for exhibition purposes.

A reading of these reports shows that in the short space of a year's time the beginnings of a splendid piece of prophylactic work have been made. The problem of a suitable sanitary privy for our rural population has been practically solved, and all that is needed is the cooperation of the country people themselves. To the missionary work of the Rockefeller Commission and the Marine-Hospital Service the southern newspapers have, in the main, given cordial cooperation, and we cannot too strongly insist on the importance of their most resolute support to this movement.

THE PRESENCE OF BACILLI IN HEALED TUBERCULOUS LESIONS

Just what constitutes healing of a tuberculous lesion is a matter of much importance and great uncertainty. It is now recognized that nearly all adult bodies contain calcified, fibroid, or encapsulated caseous tuberculous lesions, chiefly in the lungs and lymph-glands, and such lesions are commonly looked on as healed and devoid of danger. Recent studies, however, have demonstrated that the tubercle bacillus has remarkable powers of resistance which permit it to remain viable in the tissues of the host for great lengths of time, and even without producing lesions. It may be recalled that various investigators who have injected material from the lymph-glands and tonsils of cadavers into guinea-pigs, have produced tuberculosis in as high as 20 per cent. of the animals, although the glands were themselves free from either gross or microscopic evidence of tuberculosis, and were from bodies which showed no tuberculous lesions. Such a condition constitutes a true latent tuberculosis, even although there are no specific tuberculous lesions, and its apparent frequency makes us more lenient than we otherwise might be to von Behring's theory that bacilli taken in cow's milk during infancy and remaining latent during youth and adolescence constitute an ordinary source of tuberculosis in adults.

The cases in which a tuberculous lesion shows anatomic evidence of quiescence, yet contains living and virulent bacilli, should be regarded as persistent rather than latent tuberculosis. Apparently caseous tubercles practically always contain living bacilli, even when their progress has been checked and they are surrounded by a well-defined fibrous capsule. Until recently it was assumed that when calcification had taken place the lesion had been so long encapsulated that all the bacilli must be dead, but actual investigation has made it necessary to modify this view. Lydia Rabinowitsch injected into guinea-pigs material from four calcified lymph-glands of stony hardness, and in all cases tuberculosis resulted. E. Schmitz examined calcified nodules from twenty-eight autopsies, and could find tubercle bacilli with the microscope in but two; but of thirty-three guinea-pigs inoculated with material from as many calcified nodules no less than thirteen became tuberculous. As was to be expected, positive results were obtained much more frequently with material from the chalky or caseo-calcareous areas (75 per cent.) than with those of stony hardness and presumably greater age (27 per cent. positive). An important fact is that the tuberculosis produced by such inoculations was of a mild character, only one of the infected animals dying spontaneously from tuberculosis. By use of the new alkaline hypochlorite method Wegelin[1] has been able to demonstrate the tubercle bacilli much more frequently in calcified lesions, in each of three chalky and in four of ten hard calcified nodules bacilli being found.

We must, therefore, conclude that even when a tuberculous lesion has become encapsulated and calcified it is still a possible source of danger, since it may contain living tubercle bacilli. Nevertheless this danger is more potential than actual, for the mechanical protection afforded by the capsule and the lime salts must effectually prevent invasion of other tissues by the bacilli, and we have no observations which indicate that a calcified lesion is often, if ever, the starting-point of a fresh infection. Possibly if a suppurating process, or some trauma, disintegrated both capsule and lime deposits the bacilli might be set free, but even then serious trouble is not probable, for, as Schmitz' experiments have shown, the encapsulated bacilli are of such low virulence that even the susceptible guinea-pig can resist them successfully.

UNRELIABLE PHARMACEUTICAL PRODUCTS

For some years past, pharmaceutical houses have put out in tablet form an enormous number of combinations of drugs of real or fancied value. In many instances the combinations are not suited to the tablet form and it is not surprising that many of these tablets do not conform to the composition that is claimed for them. It is not to be inferred that the manufacturers wilfully put up products that are false to label, but rather that many of the combinations are pharmaceutical impossibilities. That is to say, it is pharmaceutically impossible—or at least, commercially impracticable—to manufacture, in tablet form, some of the combinations that are listed in the manufacturers' catalogues.

These tablet-combinations have been offered to the medical profession primarily because such products are considered as "business-getters" and the manufacturers seem to have tried to outvie one another in the number of combinations which they offer physicians. In most cases these tablets have been made, not to supply, but to create a demand, and as soon as one manufacturer has put out a new combination, his competitors immediately put similar combinations on the market. The result has been harmful to medicine and a discredit to pharmacy.

With the object of showing how pharmaceutically impossible it is to make some of these tablet-combinations, our chemists were asked to examine some of the several brands of tablets said to contain bismuth subnitrate, opium and phenol (carbolic acid). While this tablet is, in itself, of comparatively little importance, it was selected as a type because practically all pharmaceutical houses offer it for sale, because its manufacture offers some difficulties and because its phenol-content can be accurately determined. More than two years ago, the leading brands of these tablets were bought in open market, analyzed by the Association's chemists and the results published in THE JOURNAL.[1] Two years later, similar products of the same firms were again purchased, analyzed and the results published.[2] Both of these reports showed that the composition of the tablets examined—at least so far as their phenol-content was concerned—could not be relied on. The second examination brought out the further fact that practically all the manufacturers whose products had been examined had apparently made no effort either to modify the claims on the labels, to improve the quality of the tablets or to withdraw the product from the market.

In the "Propaganda for Reform" department of this issue appears the third, and final, article from our chemical laboratory on this subject. It will be found not only to verify the statements of the previous two articles, but also to bring out another point that is of almost as great importance as the unreliability in composition, namely, that ready-made mixtures of this type are more than likely to be several years old before they reach the physician. While this does not, of necessity, impair the efficiency of all drugs, it must in many instances be detrimental to scientific prescribing.

The three exhaustive and painstaking examinations made in the Association's laboratory and the articles that are based on these examinations teach some valuable lessons, both specifically and generally. Specifically, they show that there are probably no tablets of bismuth, opium and phenol on the market which contain the amount of phenol stated on the label; this, too, even though the tablets are obtained direct from the manufacturer. It is true that in one case the tablets obtained direct from the manufacturer contained not only all the phenol claimed, but a very appreciable percentage in excess of that amount. These tablets, however, bore such evident marks of having been "made to order" that the general findings of the laboratory were in no way vitiated. Essentially then, it has been proved that it is impracticable, if not impossible, to manufacture tablets of bismuth, opium and phenol so that the phenol-content can be relied on.

Generally, the results are of even greater importance. First is the very evident unwisdom of attempting the pharmaceutically impossible merely for the sake of achieving pharmaceutical "elegance." When one considers the enormous number of tablet combinations on the market—some firms listing over a thousand—and further realizes that undoubtedly in a great number of cases such combinations are absolutely worthless so far as accuracy of dosage is concerned, the menace that such forms of medication must be to scientific medicine becomes apparent.

---

[1] Wegelin: Cor.-Bl. f. Schweiz. Aerzte, 1910, xl, 913.

[1] July 25, 1908, p. 330.

[2] Dec. 17, 1910, p. 2169.

Second is the responsibility that rests on the pharmaceutical manufacturer for the deplorable conditions that these investigations have exposed. Physicians naturally have supposed that they could rely on the statements of such pharmaceutical firms as those whose products are affected in this exposure, at least so far as the composition of non-proprietary preparations is concerned. The defections are those of the manufacturing pharmacists. It is no excuse for them to say that they are but supplying a demand when they put out such products. The physician, of necessity, does not always realize the limitations to the art of compounding drugs and it has long been considered the function of the pharmacist to enlighten him on such technical points. In the present instance, however, the physician, instead of being advised, has been taken advantage of. Further, as has already been stated, the manufacturers are not so much supplying a demand as attempting to create a demand. Moreover, if they wish to retain the confidence of physicians they should frankly admit, when asked to put up combinations that are not pharmaceutically practicable, that it cannot be done. Instead of taking this attitude, they seem to have decided that, so long as there is money in pretending to make tablets that cannot be made, they might as well get what financial benefit they could out of the pretense.

In view of the facts brought out by our chemists, we are justified in asking a question: We know that the products examined were untrue to label when first taken up over two years ago: we know, further, that the same class of products were equally unreliable two years later, when examined the second time; we also know that still more recently these tablets, even when purchased direct from the manufacturer, are not to be depended on. Twice The Journal has given publicity to the unreliability of these products, but the manufacturers have neither profited by it nor apparently paid any attention to it. Now, for the third time, attention is directed to the same conditions. We are justified in asking, therefore: Will reputable pharmaceutical houses continue to put on the market products which they know to be not only unscientific but actually fraudulent, simply because it is "business?" The medical profession awaits the answer.

Current Comment

ROCKY MOUNTAIN SPOTTED FEVER

Through the work of the late H. T. Ricketts and others, it was demonstrated that Rocky Mountain spotted fever, an important disease in man, is conveyed by the common wood-tick of the Rocky Mountains. The disease has been found in its most virulent form in the Bitter Root valley in western Montana, the mortality in this section being from 70 to 80 per cent. The importance of ascertaining the distribution of the tick which is responsible for the transmission of such a deadly disease became apparent and, accordingly, the Bureau of Entomology of the United States Department of Agriculture in 1909 began a study of the distribution of this insect. The result of that study is published in Circular 136 of the bureau. In the investigation, specimens of the species causing the disease, *Dermacentor venustus*, were obtained from 225 different localities, embracing the states of California, Colorado, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington and Wyoming. While there are no doubt areas of considerable extent within the territory named where the tick is entirely absent, yet its distribution is much wider than was thought before this investigation, but entirely within the Rocky Mountain region. Specimens have been collected at various elevations, from 500 feet to nearly 9,000 feet above sea level. The species seems to reach its highest development and occurs in greatest numbers between 3,000 and 5,000 feet. The immature ticks have been found to feed exclusively on the small mammals and the adults on the large domestic animals. The fever may be transmitted to man in any region where this species of tick is present if the disease is once introduced into a locality by a tick from an infected region, or by man or some other animal susceptible to the malady. There is reason to believe that the disease is spreading, and therefore a knowledge of the range of this species of tick is important, so that steps may be taken to lessen the danger of its introduction into regions as yet uninfected.

A POINT IN THE MANAGEMENT OF THE INSANE

Recently a patient, having been tried, found insane, and ordered sent to an institution, was turned over to the sheriff for safe delivery. The sheriff deceived the patient, a paretic who suffered from grandiose delusions concerning money and property matters, into thinking that he was to inspect a large institution which might be made into a hotel. Thus the patient went peaceably to the insane asylum and the sheriff, having done all that he thought was required of him and transferred his charge to other hands with the least possible trouble to himself, left well satisfied with his finesse; and doubtless most persons who have had little or no experience in the care of the insane would consider his satisfaction justified. Soon the patient saw that his orders about the hotel property were not obeyed, and thus learned that he had been duped. So he protested, resisted and fought and, in spite of careful handling, sustained some bruises; his relatives raised complaint and the institution received scare-head publicity on the first page of the newspapers. An investigation was called for and held, and the exoneration of the authorities received a few lines on an inside page. The state authorities who made the investigation directed the superintendent of the institution, in the future, to make a statement to each patient brought to the institution, in the presence of the sheriff and his attendants, to the effect that the institution was an insane hospital and that the patient had been committed by law to its charge and must obey its rules and regulations. This precaution should be generally adopted.

A STRONG TESTIMONIAL

We have been interested recently to note a faint modern recrudescence of a horrific fable of our youth. Most of us have read blood-curdling tales of individuals who suddenly became human volcanoes, belching forth fire and smoke, and were in a short time utterly consumed. To judge by a recent testimonial, the ghost of the slain theory of spontaneous combustion of the human body still walks the earth. A Chicago woman testifies to her sufferings before treatment by the "United Doctors," a concern employing a number of peripatetic doctors who operate in the smaller towns in various parts of the country:

> "At this time my heart became affected also and my suffering was greatly increased by its disturbed action, causing what is commonly called 'hot flashes.' These 'hot flashes' added greatly to my misery and at times the heat from my head would burn and scorch the combs in my hair."

Needless to say, after receiving "treatment" from these noted specialists, the poor patient was restored to her former condition of well-being and comparative frigidity, and the underwriters' rates on property in her immediate neighborhood were immediately lowered.

RACE SUICIDE IN FRANCE

Statistics cited in this issue by our Paris correspondent throw an interesting light on the problem of the diminishing birth-rate in France. It seems that an official investigation has been undertaken to ascertain the probable cost of assistance to needy large families. We are told that there are in France 369,739 families having each more than four children aged less than 13. There are in these families 1,712,322 children. Nearly two-thirds of these families—237,802 to be exact—are in a permanently needy condition. When one remembers the social habits of the careful middle-class Frenchman, which render it most discreditable for a father to fail to make suitable provision for his son's start in life and his daughter's dowry, and when it appears that the greater number of the parents with large families are unable to provide, not merely for their children's future, but even for their present necessities, it becomes evident that measures against "race suicide" will have to go very deep in order to be effective.

Medical News

ALABAMA

New Hospital.—At the last meeting of the Medical Society of St. Clair County, a fund of about $5,000 was raised for the construction of a hospital at Pell City.

Antituberculosis Camp.—Through the efforts of the Montgomery Antituberculosis League, a camp has been secured for that city. Miss Julia Johnston has been elected secretary of the league.

State Society Meeting.—The annual meeting of the Medical
Association of the State of Alabama was held in Montgomery,
April 18 to 21. The following officers were elected: president,
Dr. Lewis Coleman Morris, *Birmingham*; vice-presidents, Drs.
Martin Luther Malloy, Birmingham, and Charles Lee Guice,
Gadsden; special officers of *the tuberculosis league*, Drs. Geo.
McWhorter, Riverton, and Benjamin Leon *Wyman*, Birming-
ham, and *members of the medical council*, Drs. John C. Mc-
Leod, Bay Minette; Thomas M. Littlepage, Mount Sterling;
William Alexander Graham, Fayette; Robert Henry Baird,
Cullman; Edward Harris and Wellington Prude McAdory,
Birmingham. The Jerome Cochran lecture was delivered by
Dr. Rudolph Matas, New Orleans, and was on tuberculosis.

ARKANSAS

Elections.—At the annual meeting of Logan County Medical Society, held in Magazine, April 5, the following officers were elected: president, Dr. John S. Shibley, Booneville; vice-president, Dr. Richard A. Harkins, Ratcliffe; secretary-treasurer, Dr. Austin R. Hederick, Booneville; delegate to the state society, Dr. Early E. Scott, Magazine, and alternate, Dr. E. M. Life, Scranton.——At the annual meeting of the Tenth Councilor District Medical Society, held in Rogers, March 21, the following officers were elected: president, Dr. John Young, Springdale; *vice-president, Dr. Ernest G. Epler, Fort Smith;* secretary, Dr. Dred R. Dorente, Fort Smith, and treasurer, Dr. Othello M. Bourland, Van Buren. The next meeting will be held in Fort Smith.——At the annual meeting of Lawrence County Medical Society, held at Walnut Ridge, Dr. Horace R. McCarroll, Walnut Ridge, was elected president; Dr. Wight W. Hatcher, Imboden, vice-president; Dr. John C. Swindle, Walnut Ridge, secretary; Dr. John C. Hughes, Walnut Ridge, treasurer; Dr. Gus A. Warren, Black Rock, delegate to the state society, *and Dr. William J. Robinson, Portia, alternate.*

CALIFORNIA

Personal.—Dr. E. S. Metzger has been reappointed a member of the trustees of the Redondo Beach library.——Dr. Alanson Weeks, U. S. P. H. and M.-H. Service, in charge of the United States Marine-Hospital, San Francisco, has resigned to enter private practice.

Medical Milk Commissioners Organize.—On the occasion of the annual meeting of the Medical Society of the State of California, the California Association of Medical Milk Commissioners was organized and the following officers were elected: president, Dr. Thomas McCleave, Alameda; vice-*presidents, Drs. Fitch C. E. Mattison, Los Angeles,* and Thomas A. Stoddard, Santa Barbara, and secretary, Dr. Adelaide Brown, San Francisco.

GEORGIA

Additional Officers.—At the annual meeting of the Medical Association of Georgia, held in Rome, April 19 to 21, the [illegible]ors were elected: first district, Dr. J. Lawton [illegible] second district, Dr. Jarvis G. Dean, Dawson; third district, Dr. Rupert H. Stovall, Vienna, and fourth district, Dr. Charles L. Williams, Columbus; chairman of the board of councilors, Dr. Wyman W. Pilcher, Warrenton, and editor of the *Georgia State Medical Journal*, Dr. Wm. Clifton Lyle, Augusta (reelected). The next meeting of the society will be held in Augusta.

ILLINOIS

Personal.—Dr. Albert Nicholas Mueller has resigned as a member of the board of directors of the Rock Island Municipal Tuberculosis Sanatorium.——Dr. J. T. Foster, Central City, has been appointed coroner of Marion County.——Dr. Emil W. Brust, Addison, started for Berlin, April 3.

Another Hospital for Oak Park.—The West Suburban Hospital Association has been incorporated with a capital stock of $25,000 all of which has been subscribed, and the fifteen physicians who resigned from the Oak Park Hospital are said to make up the incorporators of the new hospital. The new hospital will be located in territory convenient both to Oak *Park and Austin.*

State Board Convictions.—Mrs. J. Dunn, who claimed that she had made wonderful cures of cancers by the use of a combination of drugs and who, it is said, had been convicted before in this state, was convicted by a jury in the Municipal Court of Chicago, of violation of the Medical Practice Act, and fined $200.——M. Janik, said to be an old offender who conducts the Cracow Institute, and makes his own medicine, was convicted by a jury in the Municipal Court, and fined $200 and costs.

Chicago

Hospital Acquires Property.—The Provident Hospital *has* acquired property north of its building at Thirty-Sixth and Dearborn Streets, which will be used for the *children's department* of the institution.

To and from Europe.—*Dr.* and Mrs. Clarence E. Brinckerhoff and Dr. and Mrs. Wallace Blanchard have sailed for Europe.——Brigadier General Alfred C. Girard, U. S. Army, retired, and Dr. and Mrs. Theodore Wild, Jr., have returned from *Europe.*

INDIANA

Personal.—Dr. T. Victor Keene has been appointed a member of the board of health of Indianapolis, vice Dr. Paul F. Martin, to take effect June 1.——Dr. Herman Bowles has succeeded Dr. Clarence G. Rea as secretary of the board of health of Muncie.——Dr. Harold Pierce, Cloverland, is reported to be seriously ill with septicemia due to an operation wound. Dr. Orange G. Pfaff of Indianapolis is just recovering from infection and will go to Atlantic City.——Dr. Roscoe H. Ritter, secretary of the Indianapolis Medical Society, is critically ill at a sanatorium in Martinsville.

Ice Cream Standardized.—The State Board of Health calls the attention of all ice cream manufacturers in the state to the standard for ice cream in Indiana. Hereafter all ice cream shall have a minimum of 8 per cent. of butter fat, and 18 per cent. of milk solids and not to exceed 0.7 per cent. of gelatin or vegetable gums. Fruits, nuts, candied and preserved fruit and nuts, chocolate and other similar products should be classed as flavorings, and all ice cream containing such ingredients shall conform to the standard above specified. The addition of any color or coloring matter to ice cream to make it appear richer in butter fat, or the use of fruit color to counterfeit the color of strawberry, cherry, peach, etc., is not allowed, unless the goods are marked imitation and declare the presence of the color.

District Society Meeting.—The spring meeting of the Eighth District Medical Society was held in Portland, April 21, and was devoted principally to a consideration of cholelithiasis. At the afternoon meeting L. Ert Slack, an attorney of Franklin, spoke on "Health," pleading for a broader conception of the healing art, with special attention to the powers of the mind and the necessity of getting the patient's mind in proper attitude. The following officers were elected: Dr. Thomas Monroe Jones, Anderson, president; Dr. Charles E. Caylor, Pennville, vice-president; Dr. Fred McK. Ruby, Union City, secretary; Dr. Charles Leander Botkin, Farmland; Dr. Joseph E. Hall, Alexandria; Dr. Hamilton P. Franks, Muncie, and Dr. Charles Hollis, Hartford City, censors. The next meeting of the society will be held in Anderson, May 9, 1912.

IOWA

New Hospital.—Fort Madison is to have a new hospital to be ready September 1 and to be under the management of the Sisters of St. Francis of the Third Order.

Medical Women to Meet.—The annual session of the State Society of Iowa Medical Women will be held in Des Moines, May 16-17, under the presidency of Dr. Sophia Hinzie Scott, Des Moines.

Personal.—Dr. and Mrs. Carl W. Wahrer sailed for Europe April 12.——Dr. George P. Hanawalt, Des Moines, who has been ill for a long time, has recovered and resumed practice. ——Dr. Horace Husted has been elected health officer of Muscatine, vice Dr. Benjamin Ernest Eversmeyer.——Dr. Jay Clark Cooper, Villisca, sailed for Europe April 20.——Dr. Fred Albert has been reappointed health officer of Mason City. ——Dr. Edward Tyler Edgerly has been appointed city physician of Ottumwa.

KANSAS

Doctors' Building for Wichita.—In the new Schweiter building, Wichita, not yet entirely ready for occupancy, twenty-eight physicians thus far have arranged to rent offices.

State Hospital for Western Kansas.—Ellsworth, Scott City, Great Bend, Spearville, Norton, Wakeeney, Hill City, Larned, Downs, Ashley and Ashland make up the list of western Kansas towns thus far desiring to be considered as candidates for the location of the new state tuberculosis hospital for which $100,000 was appropriated by the last legislature.

Hospital Staff Organizes.—Twenty-four physicians of Salina were present at a meeting of the staff of St. Barnabas Hospital, April 18, called for organization. Dr. Oliver D. Walker was elected temporary president, and Dr. Jesse Wheeler temporary secretary. For permanent officers Rev. S. M. Griswold was elected president; Dr. Jonathan Harvey Winterbotham, secretary, and Drs. Oliver D. Walker, Howard N. Moses and Melchor Cockay were elected a committee to arrange the times of service for members of the staff.

Medical Society Meetings.—At the annual meeting of Smith County Medical Society, held in Smith Center, April 12, Dr. James A. McCammon, Reamsville, was elected president; Dr. Victor Watts, Womer, vice-president; Dr. Frank Relihan, Smith Center, secretary-treasurer, and Dr. Francis M. Bilby, Kensington, delegate to the State Medical Society.——At the semi-annual meeting of the Southeast Kansas Medical Association held in Independence in April, Dr. Giles A. Blasdel, Garnett, was elected president and Dr. Elmer A. Miner, Independence, secretary. The next meeting will be held in Parsons.

KENTUCKY

Ten-Cent Day.—On April 20 ten-cent day was celebrated in Louisville. The purpose of this scheme is to solicit a subscription of 10 cents from every inhabitant of Louisville, the money realized from the campaign to be turned over to the State Antituberculosis Association.——At the annual meeting of the association, held April 3, W. R. Belkner was elected president; Dr. Sam A. Hartwell, Jr., second vice-president, and Dr. Ellis S. Allen, a member of the board of directors.

LOUISIANA

Site Selected for Isolation Hospital.—The board of health of Hammond has selected a site in the southwest part of town for the new isolation hospital, the erection of which will be proceeded with at once.

Senior Student Dies.—Leon Fereol Beridon, an intern in the Charity Hospital, New Orleans, and a senior student in the Tulane University; a young man of brilliant promise; died in New Orleans, April 6, from typhoid fever, aged 23.

New Parish Society.—Jackson Parish Medical Society was organized April 20 at Eros, and the following officers were elected: president, Jacob H. Landrum, Eros; vice-president, B. E. Brown, Chatham; secretary-treasurer, Dr. A. E. Douglas, Chatham.

Sanitarium Staff Organized.—The staff of the Schumpert Memorial Sanitarium, Shreveport, has been organized with the following officers: president, Dr. J. Ashton Blanchard; vice-president, Dr. Joe J. Frater; secretary, Dr. Jacob Mahne Bodenheimer, and treasurer, Dr. Lewis Henry Pirkle.

Personal.—Major John A. Devron, Jr., M. C. N. G., La., assigned to the Second Infantry, has been detailed for duty at the maneuvers on the Mexican frontier.——Dr. Charles Chassaignac has been appointed chairman, and Dr. John Callan a member of the house committee, and Dr. Louis G. LeBeuf, a member of the finance committee of the Eye, Ear, Nose and Throat Hospital, New Orleans.

MARYLAND

State Medical Directory.—The April issue of the *Bulletin of the Medical and Chirurgical Faculty of Maryland* contains a directory of the membership of the association, which numbers 1,059, of these 1,021 are active, 18 non-residents and 20 honorary members.

Medicine and Man's Redemption.—Dr. Charles M. Ellis, Elkton, who is at present a patient in Johns Hopkins Hospital, Baltimore, suggests that the triumphs of the medical profession in the Canal Zone be recognized by a great international congress on tropical medicine to be held in Washington the year before the Panama Exposition in San Francisco, to demonstrate what medicine has accomplished for man's redemption.

Baltimore

Personal.—Dr. Robert W. Johnson has been elected president of the Churchmen's Club.——Dr. Francis M. Chisholm has moved to Washington, D. C.——Dr. James M. H. Rowland has been appointed a member of the school board.——Dr. Daniel Webster Cathell is engaged in preparing the twelfth edition of his book on "The Physician Himself" which will be published in the fall.

Hospital Report.—The twenty-ninth annual report of the Baltimore Eye, Ear and Throat Charity Hospital states that during the year 5,870 new patients were treated, 3,932 white, and 1.938 colored. Of these 5.509 wer charity patients; namely, 3,312 in the eye department; 840 in the ear department, and 1,548 in the throat department. There were 1.831 operations performed; 459 on the eye; 319 on the ear, and 1,053 on the throat. Dr. Jesse W. Downey, Jr., is superintendent of the hospital and Dr. Francis J. Hackney, resident physician.

MASSACHUSETTS

Estate Left for Research.—By the will of the late Dr. Walter Remsen Brinckerhoff, who died March 2, the entire estate is left to his son, a minor. In the event of the death of the son, two-fifths of the estate is to go to Harvard College to found a memorial to the wife of Dr. Brinckerhoff, the income to be spent for scientific research on communicable diseases.

MINNESOTA

Personal.—Dr. Charles O. Cooley, Madelia, is seriously ill at his home in Madelia.——Dr. John A. Winter, Duluth, has been appointed assistant in the eye, ear and throat department of the St. Louis County tuberculosis clinic.——Dr. N. L. Linneman, Duluth. has returned from Europe.——Dr. Ignatius J. Murphy has been appointed police surgeon of Duluth.

Association Meeting.—The annual meeting of the Stearns-Benton Medical Association was held, April 20, in St. Cloud. Dr. Harold Lamb, Sauk Centre, was elected president; Dr. Charles Stewart Sutton, St. Cloud, vice-president; Dr. John C. Boehm, St. Cloud. secretary and treasurer; Dr. Warren L. Beebe, St. Cloud, delegate to the state association, and Dr. James H. Beaty, censor.

The Antituberculosis War.—The annual report of the Minnesota Association for the Prevention and Relief of Tuberculosis for 1910 shows that during the year $4,295 was received and $4,740 expended; and that at the end of the year there was a balance in hand of $212.09.——Plans for the St. Louis County Tuberculosis Sanatorium have been accepted and the building will be ready for occupancy in the fall. The institution will have an initial capacity of seventy patients and the first unit will cost $30,000. The sanatorium is located north of Fond du Lac and is 700 feet above the lake level.

MISSOURI

New Hospital.—St. Joseph's Convent of Mercy has raised $300,000 to build the new St. John's Hospital, St. Louis, on a tract near Forest Park with frontage on Euclid and Audubon Avenues and Park View. The institution is estimated to cost $380,000 in addition to the site.

Wants Merit System.—The hospital committee of the St. Louis Society of Medical Research, at its meeting April 25, announced that a bill would be presented before the municipal assembly. asking that a merit system be substituted for the present hospital commission system in the new City Hospital.

Change in Meeting Place.—Owing to the destruction by fire of the state capitol at Jefferson City, the place of meeting of the Missouri State Medical Association has been changed to Kansas City. The meeting will be held on the dates originally set, May 16-18. Headquarters will be in the Coates House and the sessions will be held in the Coates House and Casino Hall, which adjoins the hotel.

Alumni Reunion Dinner.—An invitation has been issued to the alumni of the Missouri Medical College, St. Louis Medical College and Washington University Medical School to take part in a social reunion and dinner at Kansas City, May 17, during the meeting of the Missouri State Medical Association. Tickets stating time and place may be had by addressing Dr. Richard S. Weiss, 346 North Boyle Avenue, St. Louis.

Personal.—Dr. Abra C. Pettijohn, Brookfield, has been reappointed superintendent of State Hospital No. 2, St. Joseph; Dr. E. H. Trowbridge, Kansas City, has been appointed assistant physician, vice Dr. W. E. Carey, Kansas City, resigned; Dr. Ashman H. Vandivert has been reappointed assistant physician, and Dr. Harlan P. Mills assistant physician and bacteriologist.——Dr. Cleveland H. Shutt, St. Louis, has returned from abroad.——Dr. Ernest F. Robinson has been appointed chief surgeon of the Kansas City Terminal Railway Company.

NEW HAMPSHIRE

State Society Meeting.—The one hundred and twentieth annual meeting of the New Hampshire Medical Society will be held at Concord May 11-12. The meeting of the House of Delegates will be held on the evening of May 10, under the presidency of Dr. Alonzo Stewart Wallace. Nashua. On the first day there will be a symposium on ophthalmia neonatorum with general consideration by Dr. Louis W. Flanders. Dover, and a discussion from the standpoint of the general practitioner by Dr. E. C. Batchelder. Dover; and from the standpoint of the specialist by Dr. Charles Francis Nutter, Nashua; a paper on "Medical Practice Laws" by Dr. John Martin Gile, Hanover, and one on "Rational Medical Treatment" by Dr. Elbert A. Landman, Plaistow. Among the important papers to be considered on the second day are those on "Medical Inspection of Schools." by Dr. Zatae Songsdorf Straw of Manchester, and "The Treatment of Medical Subjects by the Lay Press" by Dr. Henry O. Smith of Hudson Center.

NEW YORK

No Vivisection Inquiry.—By a vote of 34 to 11 the senate defeated the Bayne bill creating a commission to inquire into the nature and practice of experimentation on living animals and the status of the present laws regarding vivisection.

Investigation of Hospitals and Penal Institutions.—Following the appointment of a committee for the purpose of investigating conditions in the Matteawan and Dannemora state hospitals. a general investigation by a legislative committee of conditions in all New York prisons, hospitals and penitentiaries is called for by a resolution introduced by Senator Stillwell. The resolution carries an appropriation of $25,000.

Medical Examiners Appointed.—The following have been appointed as members of the State Board of Medical Examiners by the State Board of Regents: Drs. Arthur W. Booth, Elmira; Aaron B. Miller, Syracuse; Henry B. Minton. Brooklyn; Floyd S. Farmsworth, Plattsburg, and Ralph H. Williams, Rochester.

New York City

For Convalescent Home.—Sixty acres of ground has been purchased by the Burke Foundation on Manaroneck Avenue, White Plains, at a cost of $180.000. Cottages will be built here that will furnish accommodations for 300 patients, convalescents of New York hospitals.

Hospital to Teach Hygiene.—The Union Hospital which has leased the old Fordham Hospital building, opened May 1. It will undertake to teach office hygiene, to direct business and professional men, educators and ministers in sanitary conditions under which they should work. The president of the association is Dr. John F. Holmes, and the vice-presidents are Drs. Nathan B. VanEtten and Frederick W. Loughran.

Funds for Hospitals.—The Presbyterian Hospital won a bequest of $100,000 in the Supreme Court when it was decided that the first will of Edward O. Kindberg was valid and that his second will was invalid.——The will of Bernard G. Amend leaves $2,000 to the German Hospital.——The New York Dispensary, having recently established a social service department which takes care of sick persons and on their recovery finds them employment, has had its activities threatened through lack of funds and has sent out an appeal for help.——The Methodist Episcopal Hospital of Brooklyn will receive $5.000 by the will of the late William Lawrence of Goshen. N. Y.——Mrs. Adolph Scheftel has given $10,000 to the Montefiore Home for Chronic Invalids to endow a ward for the treatment of locomotor ataxia. This gift is in memory of Adolph Scheftel.——By the will of Mrs. Alice A. Hicks of Old Westbury, L. I., the Nassau Hospital Association will receive $100,000, and the New York Association for Improving the Condition of the Poor, $50,000.——A special performance at Wallack's Theater, by stage children, netted $4,000 for St. Mary's Free Hospital for Children.

Hospital Saturday and Sunday.—The distributing committee of the Hospital Saturday and Sunday Association announces that $112,000 has been raised this year. The apportionment among hospitals is based on the amount of certified free service given by each hospital, and is as follows: Montefiore Home and Hospital for Chronic Invalids. $9,400; Mount Sinai Hospital, $8,669; St. Luke's Hospital, $5,345; Orthopedic Dispensary and Hospital, $4,786; German Hospital, $4,352; St. Mary's Free Hospital for Children, $4,094; Home of the Sisters of Misericordia, $3,845; Ruptured and Crippled Hospital, $4.768; Post Graduate Hospital, $3,737; Roosevelt Hospital. $3.683; Lincoln Home and Hospital, $3,486; Lebanon Hospital. $3.483; Hospital for the Lying-In Society, $2,610; Beth Israel Hospital. $2.570; Home for Incurables, $2,204; House of the Holy Comforter, $1,940; Isabella Heimath, $1,834; Manhattan Eye, Ear, Nose and Throat Hospital, $1.788; House of Rest for Consumptives, $1,567; New York Eye and Ear Infirmary. $1.432; Babies' Hospital, $1,399; Flower Hospital, $1,360; Sloane Maternity, $1,107; St. Mark's Hospital, $1,048, and Hospital of the French Benevolent Society, $1,007. Many other hospitals received smaller sums.

PENNSYLVANIA

Measles Closes Schools.—Bryn Mawr College and all public, private and parochial schools in lower Merion Township. even Sunday schools, were ordered closed, April 27, by the board of health, until May 8, pending a thorough fumigation by an augmented squad of health inspectors. This drastic action which also prevents all public meetings of children and young people in the township, was taken as a result of the alarming spread of measles.

Dairy Farms Inspected.—In the campaign for pure milk over 50.000 dairy farms are being inspected by the officers of the State Department of Health. After inspections the farmers receive notice from the state commissioner of health that certain conditions must be remedied and are given to understand that unless sanitary improvements are made the public will not accept the milk produced. The reports of the department show that each inspection has been productive of greatly improved sanitary conditions.

Philadelphia

Bequest to Medical College.—By the will of the late Annie Shoemaker, Swarthmore, the Woman's Medical College of Pennsylvania will receive a bequest of $3,000.

Personal.—Dr. John Herr Musser, Philadelphia, sailed for London April 13.——Dr. George W. Norris has been elected visiting physician to the Episcopal Hospital, vice Dr. David L. Edsall, resigned.

Portraits Presented.—At a meeting of the College of Physicians, April 5, portraits were presented to the college of the late Dr. George Couvier Harland and Dr. James Tyson. Both portraits were accepted by Dr. George E. de Schweinitz, president of the college.

Alumni Room for Jefferson.—The alumni association of Jefferson Medical College has appointed Drs. W. M. Late Coplin, George Evans Reading and Pascal Brooke Bland a committee to devise ways and means to secure funds for the perpetual endowment of a room in the Jefferson Medical College Hospital, to be used for the free treatment of any ethical graduate of the college.

Fellowship for Medical Research.—Friends of the late Dr. J. Allison Scott, adjunct professor of medicine in the University of Pennsylvania, have contributed $10,000 for the establishment of a memorial. It has been decided to make this in the form of a fellowship for medical research. About $200 of the interest will be used to help some worthy third or fourth year medical student to complete his course, and the remainder of the interest will be invested until the entire sum is sufficiently large to constitute a proper endowment for research work.

Milk Temperature Regulation Violated.—The board of health's regulation requiring the temperature of milk shipped into this city to be not more than 60 degrees is being violated every day, according to J. W. Pancoast of the Interstate Shippers' Association, for large quantities of milk are being sent daily to the various receiving stations of the large milk dealers at a temperature of 75 to 85 degrees F. The producers think it unfair that farmers who send milk directly to the city should be compelled to conform to this regulation while farmers supplying receiving stations may send milk at any temperature.

Work on Open-Air School Halted.—For the second time the work of installing an open-air school in this city has been interrupted. The present delay arises from a disagreement between J. Horace Cook, superintendent of the board of buildings and Alexander Wilson, secretary of the Phipps Institute. When the project was started, the institute agreed to assume all the expenses of fitting up the class room, furnish warm clothing for the pupils and provide milk and eggs. The plans for fitting up the roof of the McCall School at Seventh and Lombard Streets, were submitted to Superintendent Cook, who says the proposed structure will have a tendency to deface the school building.

Pennsylvania Tuberculosis Society Meeting.—The annual meeting of the Pennsylvania Society for the Prevention of Tuberculosis was held at the College of Physicians, April 11. J. Byron Deacon, the executive secretary, emphasized the need of Hospitals for advanced cases of consumption, a plea that Dr. Lawrence F. Flick has made for several years. Dr. James Tyson declined to serve again as president and Asa S. Wing was elected to the office. Other officers chosen include: vice-presidents, Drs. James Tyson, Joseph S. Neff, William Duffield Robinson, William Charles White and Talcott Williams; treasurer, Dr. James Gurney Taylor; secretary, Dr. Ward Brinton, and directors, Mrs. Charles F. Jenks, Mrs. Lawrence Lewis, Jr., Miss Henrietta Ely, Francis R. Cope, Jr., and Drs. Henry Robert Munsy Landis and James M. Anders.

Care of Scholars' Teeth.—Twenty thousand toothbrushes and forty gross of tooth powder will be distributed free to public school children by Dr. P. B. McCullough and his assistants at City Hall at the free dental clinic. Dentists of the city in practice more than twenty years raised the fund for this purpose. These will be given each child when his mouth has been put in proper condition at the clinic. At one school, where examinations of the mouths of 110 children were made, only 6 sets of perfect teeth were found. Dr. Joseph S. Neff, director of public health and charities, feels it necessary to have salaried dentists for the work in the free clinic as it is not possible to depend on the corps of volunteer dentists, which in the beginning numbered 200 but now has dwindled to scarcely half a dozen. Councils will be called on to support the clinic.

GENERAL NEWS

Dominion Physicians to Meet.—The forty-fourth annual meeting of the Canada Medical Association will be held in Montreal, June 7, 8 and 9. Sir James Barr, Liverpool, England, will deliver the address in medicine and Dr. Alexander Primrose, Toronto, the address in surgery. Dr. William J. Mayo, Rochester, Minn., will read a paper on "Gallstone Disease," and Dr. Casey A. Wood of Chicago is on the program in the ophthalmologic section.

Change Date of Climatological Meet.—It is announced that the scientific sessions of the twenty-eighth annual meeting of the American Climatological Society will be held in Montreal, Que., June 13-14. The plans contemplate a stay at Saranac Lake, N. Y., June 12, with a visit to the Adirondack Cottage Sanatorium and the New York Sanatorium at Raybrook. The preliminary program includes twenty-two titles, notable among which are the papers by Dr. James M. Anders, Philadelphia, on "The Climatic and Hygienic Influences of Forest Growth;" by Dr. Richard Cole Newton, Montclair, N. J., on "Some of the Laws for the Treatment of Consumption Laid Down by Sydenham and His Successors;" by Dr. David R. Wyman, Wallingford, Conn., on "The Economic Value of Sanatorium Treatment of Pulmonary Tuberculosis;" by Edward Osgood Otis, Boston, on "Blood-Pressure and Physical Exertion;" and by Henry Robert Munsy Landis, Philadelphia, on "After History of Patients Treated in the Phipps Institute."

Medical Sociologists to Meet.—The American Society of Medical Sociology will hold a meeting in the Academy of Medicine, New York City, May 12. The papers of the evening are "What Animal Experimentation or So-Called Vivisection has Accomplished for Mankind," by Dr. James P. Warbasse, Brooklyn; "The Control of Prostitution and of Venereal Disease in This Country and Abroad," by Dr. Frederick Bierhoff, New York City; and "The Question of Abortion from a Social and Ethical Point of View," by Dr. William Josephus Robinson, New York City. The discussion will be opened by Dr. Abraham Jacobi.

Recent Deaths in the Profession Abroad.—In addition to those mentioned by our correspondents, the following deaths have been reported: J. F. Hempel, surgeon-general of the Danish army, died March 8, aged 63.——P. Patron, a leading physician of Peru and on the editorial staff of the *Cronica Medica* of Lima, Peru.——E. E. del Arca, dean of the medical department of the University of Buenos Aires, where he was professor of materia medica, collaborator on the Codex Argentina, member of the state legislature and president of the school board, died March 21, aged 57.

LONDON LETTER

(From Our Regular Correspondent)

London, April 22, 1911.

Notification of Consumption at Hospitals

The local government board has issued an order embodying further regulations for the notification of cases of pulmonary tuberculosis occurring among the in-patients or out-patients of hospitals and other institutions for the treatment of the sick, which are supported wholly or partially otherwise than by the contributions of the patients. This regulation carries the notification of tuberculosis another step forward. Previously notification was necessary only in the infirmaries provided by the state.

Shellfish and Disease

The dangerous conditions from sewage contamination under which oysters are liable to be collected, fattened or stored, have for several years attracted the attention of health officers. Since 1898, outbreaks of typhoid fever have been traced to this source in England. To cockles similarly contaminated in Belfast Lough the prevalence of typhoid in Belfast is attributed. Dr. Bulstrode, inspector of the local government board, has issued a very important report on "Shellfish Other Than Oysters in Relation to Disease" in which he reviews the evidence connecting the consumption of mollusks with typhoid fever and gastro-enteritis. It has been fairly easy to establish the connection in cases in which a large number of persons partake of these and become ill soon afterward. But in addition to these cases, local investigations made by health officers during the last twenty years have shown that shellfish probably have caused, and are still causing, a serious number of sporadic cases of typhoid fever which contribute largely to maintain its endemic prevalence. Thus in the urban district of Ormesby, Dr. Johnson, the health officer, has shown that of the patients suffering from typhoid fever, 25 per cent. had eaten shellfish from a contaminated source a short time before, while among a large proportion of the population only 7.3 per cent had eaten shellfish during the whole of the summer. Dr. Bulstrode declares that means must be devised whereby shellfish for human consumption shall no longer be laid down, stored, washed in, or gathered from, positions liable to sewage contamination. The places from which shellfish are procured, cleansed or prepared for market must be periodically inspected. In the meantime, until proper regulations can be enforced, persons who desire to avoid typhoid should consume shellfish only after they have been cooked at the boiling point for at least five minutes.

PARIS LETTER

(From Our Regular Correspondent)

Paris, April 21, 1911.

First Aid To Injured Workmen

The president of the Conseil général de la Seine has just received a petition from Dr. Rémy, *agrégé* professor of the Faculté de médecine de Paris, requesting authority to open courses in the professional schools of the city of Paris to train working men to give first aid to injured comrades until the physician should arrive. The Syndicat des Médecins de la Seine has passed a resolution protesting energetically against this petition on the ground that the first dressing should be made with as perfect asepsis and antisepsis as possible.

Responsibility of the Author of a Work of Popular Medicine for a Typographical Error

A cabinet-maker, coming home drunk and realizing his own condition, asked his wife to send to the nearest druggist for something to sober him. His wife consulted a book which she had, the "Médecin du peuple," and found a formula calling for 100 gm. of water, 15 gm. of peppermint water and 15 gm. of ammonia water, to be taken in two or three doses; this she carefully copied and sent to the druggist. The cabinet-maker took the potion and died. The book in question, written by Dr. Georges Migot under the pseudonym of "Dr. Davaud," was first published at Ghent and republished at Paris. In the reprint a serious error crept into the formula copied by the cabinet-maker's wife. The amount of ammonia was given as 15 grams instead of 15 drops. Dr. Migot and the pharmacist were both prosecuted for manslaughter, the one for not having verified his formulas and the other for delivering a remedy without a prescription and without fulfilling the conditions demanded by law. The cabinet-maker's widow, as civil party to the suit, demanded for herself and her two children $8,000 (40,000 francs) damages. Dr. Migot was condemned to three months in prison and the pharmacist to one month. The widow was awarded damages of $200 (1,000 francs) and an annual payment of $60 (300 francs) for herself and $40 (200 francs) a year for each of her two children until they shall be 18 years old. Two-thirds of this pecuniary recompense is to be at the charge of the author of the book in question and one-third is to be charged to the pharmacist.

Large Families in Indigence

An official investigation has been made throughout France into the number of large and indigent families, in order to ascertain the probable cost of monthly relief to such families. It appears that the number of families having from four to ten children, aged less than 13, is 369,739, the total number of children being 1,712,322. Among these 237,802, having 1,078,855 children, are in a condition of permanent indigence.

Protest Against a Play Derogatory to the Medical Profession

A play is now being presented in a Paris theater containing violent attacks against the medical profession. The physicians in this theater have resigned. The Conseil général des Sociétés médicales d'arrondissement de Paris has just unanimously voted its congratulations to the physicians of the theater for not countenancing such outrages by their presence. They call on all their colleagues to follow this example, relying on the professional dignity and solidarity to insure that no physician shall take the place of the physicians who have resigned.

The Signs Displayed by Midwives

Some midwives place at their doors signs announcing that they treat diseases of women. On the complaint of the Syndicat des Médecins de la Seine the prefecture of police has ordered these midwives to suppress all such notices. It is to be hoped that the administration will extend this measure to masseurs and healers of all kinds, and will thereby put an end to an abuse which has lasted too long to the injury of the medical profession.

Has a Physician the Right to Inject a Non-Authorized Serum?

The courts have recently had to pass on the case of a physician, Dr. Lorot of Paris, who was prosecuted for manufacturing and selling without authorization an antituberculous serum called "toxyline." This serum was, according to M. Guignard, director of the Ecole supérieure de pharmacie de Paris, composed of three other serums; one an antityphoid serum, one an antistreptococcus serum coming from the Pasteur Institute of Paris, and the other, the name of which Dr. Lorot was unwilling to give, coming from the Pasteur Institute of Lille. Dr. Lorot's defense was that he did not sell toxyline to patients or to physicians, but that the injections that he made were comprised in the treatment that he gave. Dr. Lorot was acquitted and the court of appeals confirmed the decision of the lower court on the ground that, while the law prohibits the sale of serums not authorized by the government, the injection in the course of treatment, even though it is a serum, should not be considered as a sale.

Treatment of Obesity

On April 11 Professor Albert Robin read before the Académie de médecine a paper on the treatment of obesity by a strictly hygienic and dietetic régime without the administration of any drug and without any quantitative restriction of food or drink. This treatment consists essentially in having the patient take fractioned meals. The first meal in the morning consists of cold meat or fish and hot water with a little tea, and is followed by half an hour's walk. At half past ten the patient eats one or two eggs, drinks hot water and then takes a walk of half an hour. This meal is intended especially to blunt the edge of hunger for the midday meal, for which the patient takes cold meat, a vegetable salad, fresh vegetables and fruit, hot water as before, and then a walk for half an hour. At 5 o'clock he takes a light luncheon with hot drink and a walk afterward; in the evening, a meal like that at noon, but with hot meat, and another walk. This frequency of meals is intended to suppress the sensation of hunger as the ingestion of aromatic hot water restrains thirst, while greatly limiting the quantity of liquid ingested. The treatment is almost always successful. In any case, one may ascertain the outcome very early by measuring the total urine of the two or three days preceding the treatment and, likewise, the urine of the days following. If the treatment is to be successful, an increase of the quantity of urine is immediately observed.

Dr. Maurice de Fleury remarked that Professor Robin was right to reject the starvation treatments, which are always harmful to obese subjects who are affected with tuberculosis.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, April 13, 1911.

Personal

Dr. Königshöfer, professor of ophthalmology at the veterinary college at Stuttgart, died a few days ago at the age of 59. He secured his preparation for his specialty as assistant to Professor Michel at Erlangen, and has published many investigations in the field of ophthalmology. Moreover, he was active in a scientific and practical way in social hygiene, and did good service as an advocate of the interests of the medical profession, especially for the introduction of the free choice of physicians. It was largely due to him that free choice of physicians in hospitals was introduced in the state hospitals for the railroad and post-office employees of the kingdom of Würtemberg. Königshöfer belonged to the business committee of the German medical league (*Deutscher Aerztevereinsbund*).

Alcohol and Misdemeanors in the Army and Navy

Some interesting facts are given in a recently published article regarding the connection between alcohol and misdemeanors in the German army and navy. According to this article, the offenses committed from drunkenness against military discipline in the army have ranged from 9.6 to 12.5 per cent. of the total misdemeanors in the last ten years, and in the navy from 11.1 to 22.3 per cent. This does not include slight infractions of military order; of the most serious offenses against military discipline (actual attack, mutiny, insubordination) about three-fourths are due to the clouding of the consciousness by alcohol. The geographical distribution of the offenders is also interesting. In the eastern provinces alcohol is used under its purest forms as whisky, while in the west more wine is drunk, although in the Rhine provinces absinthe is also used, and in Bavaria beer has the preference. The abuse of alcoholic drinks is regulated by the habits of the people of the various divisions of the country.

Repeal of the Tuberculin Test for Imported Cattle

Serious objections have repeatedly been made by German agriculturists against the tuberculin test prescribed to protect the German cattle industry against the importation of foreign diseased animals. On the one hand animals have been rejected on account of their violent reaction to the tuberculin test, which when slaughtered showed only slight tuberculous lesions, conditions that did not necessitate the exclusion of the cattle. On the other hand, it has been established that foreign cattlemen have learned to immunize their cattle to tuberculin, so that animals have passed the test and their importation has been allowed, when later they have proved to be tuberculous. The federal council (*Bundesrat*) has taken cognizance of these complaints, and at its last sitting adopted new regulations for the quarantine of animals imported by way of the sea. The tuberculin test is to be abolished after July 1 and replaced by a clinical investigation.

Hotel Proprietors and the International Hygiene Exposition

At a meeting of the directors of the association for the promotion of commerce between Dresden and foreign places, the chairman stated that the Dresden branch of the international association of hotel proprietors had decided not to impair the invitation of Dresden to foreign cities by a special advance in prices during the international exposition of hygiene, but to support this hospitality by accommodating service. It would be very satisfactory if the Dresden exposition could be made notable above other similar affairs by the carrying out of this resolution.

Municipal Institutions for the Care of Sufferers from Pulmonary and Laryngeal Affections

The Berlin authorities have decided to establish a station for the care of pulmonary and laryngeal patients at Buch, a sewage-farm district belonging to Berlin, where already important municipal institutions are situated, particularly the pesthouse, an insane asylum and a hospital for pulmonary patients. The building of a pavilion is contemplated providing for 500 beds, with a possible enlargement to 1,000 beds.

Education of Blind and Deaf and Dumb Children

The upper house of parliament at one of its recent sessions adopted a law for regulating the schooling of blind and deaf and dumb children. In special institutions for the blind, attendance at school is to begin at the sixth year and that for the dumb at the seventh year. For children who are retarded in their development the school attendance is to be postponed three years. As for children who are both blind and deaf and dumb, a special resolution was passed declaring that legal regulations for school attendance were not applicable to such children at present. The government was requested, however, to give particular attention to the schooling and education of such children. As soon as methods for the training of these children have been successfully developed and it is possible to assemble blind, deaf and dumb children in an institution, regulations for their attendance at school are to be established.

BUDAPEST LETTER

(From Our Occasional Correspondent)

Budapest, April 10, 1911.

Wood Alcohol Poisoning

Dr. Felletar, director of the Public Analytical Office, in a lecture at a recent meeting of the local medical society, gave some object-lessons on the recent multiple poisoning by wood spirit. He said that in the majority of these cases the persons affected have been of alcoholic habits and have taken to the drinking of the methyl spirit either from a liking for it or as a substitute for unattainable ethyl alcohol. The fatal dose in these cases was half an ounce. One of the patients was poisoned by inhalation of the vapor, and another by absorption through the skin. Both of these were workmen in a distillery. This shows, said Felletar, that in manufactories where large quantities of methyl spirit are used it is necessary to provide for an extra supply of fresh air to the workers. In the cases quoted by Felletar the most constant symptoms of the poisoning were mild intoxication followed by severe headache, gastric pain, retching, dilatation of the pupils and partial or complete blindness. In the most serious cases this sequence was followed by dyspnea, coma with stertorous breathing and death. The toxic amblyopia, continued the lecturer, is of all these symptoms the most constant and important, since even when recovery takes place, atrophy of the optic nerve is likely to follow the neuritis, and permanent blindness is the result. The immediate cause of death in fatal cases is not clear, though respiratory paralysis sometimes precedes circulatory failure. It is thought that the toxicity of the drug may be greatly increased by the production of formates in the body by the decomposition of the methyl alcohol; and formates have actually been discovered in two of these patients. Whatever be the exact pathology of the condition, there is no doubt that the intense toxicity of methyl alcohol calls for extreme caution in its use. It is, moreover, the duty of the profession to see that the public are properly instructed on the point.

Syphilis in Physicians

Dr. Sellei, dermatologist to the Teleia Hospital, recently urged the necessity of counting syphilis as an "occupation disease" of physicians. He has had as patients seven medical men suffering from the disease (Professor Blaschko had twelve). The primary lesion occurred in nearly every case on the hands, and was received in the course of gynecologic examination or operation. In some of the cases the cause of infection was the accidental wounding of the finger with an instrument, but in most it occurred through some unnoticed scratch or minute lesion. In one case, indeed, infection was definitely traced to the performance of an autopsy on a syphilitic. The primary lesion in Sellei's cases was usually very small and by no means painful, and presented some difficulty in diagnosis; in particular, it had to be distinguished from herpes, from anatomic tubercle, and from chancroid. Sellei advises against excessive use of the scrubbing-brush in preparation for gynecologic examinations, as he thinks it is responsible for many slight traumata about the fingers. He advises, too, the more frequent use of gloves in general gynecologic work.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, April 18, 1911.

Military Facilities for Medical Students

The proposed new regulations of the compulsory military service contain some provisions dealing with medical students. Hitherto the rule for the service in the ranks has been three years for the bulk of the population. Medical and certain other students, as well as a few groups of persons having a university education, had the privilege of serving but one year with the colors. The medical students had to serve half a year with the ranks before graduating, and then after having obtained their regular M.D. diploma, they had to serve another six months in the army hospitals. The new plan requires a two-year service with the colors for the bulk, one year for persons with college education, and for medical students three months' service with the rank and file, while the other nine months will be spent in hospitals of the army. Furthermore, the three months of actual army service can be taken during the annual summer vacations, July-September, so that the medical student will no more lose half a year of his curriculum as hitherto. The nine months of hospital service are to be divided up chiefly between surgical and medical wards. Specialist tendencies to be favored whenever present. The military service will, in future, be postponable up till the twenty-eighth year of the student or doctor. After serving his term the doctor will hold the rank of "Oberarzt" (a little less than captain), in his private position. The facilities for medical students have been made necessary by the lack of first-class men in the Army Medical Corps, for nearly all doctors who are capable to do so, leave the army on account of the unsatisfactory position they have to expect there.

Medical Men and the Dissolution of Parliament

The unexpected dissolution of the Austrian parliament has just now come as a welcome period of preparation for the medical profession. The defunct parliament had no more than nine medical members out of a total of 425. They were quite inadequate to cope with the problems confronting our profession just now. The social legislation was framed in such a way that the doctor would have been the sufferer. In previous Vienna letters (The Journal, Dec. 11 and 25, 1909, pp. 2019, 2171; May 7, 1910, p. 1558) it was explained that a grand action was deliberated in parliament to secure free medical aid for a large proportion of the population by means of compulsory membership in a Krankenkasse or friendly society. While the profession wanted a certain income limit of 2,400-3,000 kronen ($500-$600) on the part of the insured members, so that persons earning more than that yearly income should not become members of this Krankenkasse, parliament had framed a bill in which no income limit was fixed and all wage-earners could have availed themselves of the opportunity of cheap medical help. This bill spelled ruin to many a private practitioner. By the dissolution of parliament the bill is done away with for a time. Meanwhile the profession has started an energetic action to bring in as many doctors as possible into the new house to be elected in June. All local branches have been asked to nominate medical candidates and the cooperation of influential political parties will be sought after in this endeavor. Especially in certain country districts and in some towns, where the doctor plays a prominent part among the population, there is reason to expect the return of the practitioner into the house. Then, of course, when the bill is again introduced, amendments more suitable to the needs of the profession will be likely to be carried. All the more, as also a new "epidemic act," a "medical regulation act" and a "health officers' act" are under consideration. There will be plenty of opportunity for useful work for would-be members of parliament who are doctors too.

Marriages

JAMES S. ARCHIBALD, M.D., Nokomis, Ill., to Miss Julia Le Hurt of St. Louis, at Edwardsville, Ill., April 15.

EDWIN A. GRIFFIN, M.D., Manhattan, New York City, to Miss Ethel Frances Gibson of Brooklyn, April 12.

CHARLES LEWIS FRANKLIN, M.D., Des Moines, Ia., to Miss Maria Helen Richardson of Chicago, April 26.

CARL O. BERNHARDI, M.D., Jr., Rock Island, Ill., to Miss Edith Snyder of Terre Haute, Ind., April 19.

CHARLES WHEELER WALKER, M.D., to Miss Mary Elizabeth Gaffney, both of Rye, N. Y., April 16.

HUGH PAYNE GREELEY, M.D., Boston, to Miss Floretta Elmore of Milwaukee, Wis., April 20.

CLARENCE E. BRINCKERHOFF, M.D., to Miss Mildred Kathryn Cooney, both of Chicago, April 27.

HEBER BUTTS, M.D., U. S. Navy, to Miss Maude M. Grimes of Washington, D. C., April 17.

EARL B. BUSH, M.D., Ames, Ia., to Miss Edna Evans of Worthington, Minn., April 15.

HENRY M. FINE, M.D., to Mrs. Margaret Havermale, both of Oakland, Cal., April 18.

HENRY B. DECHERD, M.D., to Miss Fannie Dealey, both of Dallas, Tex., April 12.

Deaths

Manning Simons, M.D. Medical College of the State of South Carolina, Charleston, 1868; a member of the American Medical Association; one of the most prominent and successful of the older generation of South Carolina physicians and surgeons; died at his home in Charleston, April 18, from heart disease, aged 64. Almost from the time of his graduation he was a member of the teaching staff of his alma mater as professor of abdominal surgery and gynecology. He was for many years surgeon to the Roper Hospital and the St. Francis Xavier Infirmary. He was formerly president of the South Carolina Medical Association, the Tri-State Medical Association of Virginia and the Carolinas, and the Southern Surgical and Gynecological Association; and was a member of the American Association of Physicians and Gynecologists and International Association of Railway Surgeons. Dr. Simons was local surgeon to the Southern Railway and the Charleston Consolidated Railway and Lighting Company.

Herman Knapp, M.D., an eminent ophthalmologist of New York City; died in Mamaroneck, N. Y., May 1, aged 79. He was born in Dauborn, Prussia, received his degree in medicine at the University of Giessen in 1854, and made studies in ophthalmology in Germany, France and England, thereafter. He became professor of ophthalmology in Heidelberg University in 1864 and continued in that position for four years, when he came to America. He settled in New York City in 1868 and founded the New York Ophthalmic and Aural Institute a year later. In 1869 he also established the *Archives of Ophthalmology and Otology*, of which he was editor for many years. From 1882 to 1888 he was professor of ophthalmology in the New York University Medical College. From 1888 to 1902 he occupied the same chair in the College of Physicians and Surgeons, New York City and, in the latter year, was made emeritus professor.

John Bedford Shober, M.D. University of Pennsylvania, Philadelphia, 1885; died in the German Hospital, Philadelphia, April 27, after an operation for the removal of gall-stones, aged 51. He was a member of the American Medical Association, The College of Physicians of Philadelphia, and the Philadelphia Medical Club; gynecologist to the American Hospital for Diseases of the Stomach and the Howard and Gynecean hospitals, Philadelphia, and to the Bar Harbor (Maine) Medical and Surgical Hospital. Dr. Shober practiced in Philadelphia excepting from June to October of each year, when he resided in Bar Harbor, Me.

Alexander H. Crosby (license, Lewis County, N. Y., 1862); a member of the American Medical Association; and a practitioner of Lewis County for nearly fifty years; in 1875, a member of the state legislature; and for several years a member of the county pension examining board; died at his home in Lowville, March 2, from carcinoma of the liver, aged 74. Lewis County Medical Society, at a special meeting, held March 3, adopted appropriate resolutions regarding the death of Dr. Crosby.

William Green, M.D. Jefferson Medical College, 1858; a member of the Medical and Chirurgical Faculty of Maryland; and chief surgeon in the Confederate Army on the staff of Gen. Robert E. Lee during the Civil War; at one time president of the Baltimore Clinical Society; for several years professor of materia medica and therapeutics in Washington University, Baltimore; died at his home in that city, April 16, from heart disease, aged 74.

Thomas Peter Scully, M.D. Albany (N. Y.) Medical College, 1885; a member of the Medical Society of the State of New York; formerly president of the Oneida County Medical Society; a member of the staff of the Rome Hospital; a member of the Rome board of health, and formerly of the board of health of Cohoes; died at his home, April 19, from pneumonia, aged 41.

Arthur Case Fitch, M.D. George Washington University, Washington, D. C., 1903; formerly night medical officer of the Government Hospital for the Insane, Washington; but for the last two years a resident of Porto Bello, Brazil; and quarantine officer of the Maderra-Manore Railway Company; died suddenly in Porto Bello April 6, from cerebral meningitis, aged 34.

J. Wiltsie Knapp, M.D. Albany (N. Y.) Medical College, 1872; a member of the Medical Society of the State of New York; for six years demonstrator of anatomy in the Syracuse University; for two terms coroner of Onondaga County, and later president of the local board of pension examiners; died at his home in West End, Syracuse, April 14, from nephritis, aged 58.

Edwin Farnham, M.D. University of Pennsylvania, Philadelphia, 1869; a member of the Massachusetts Medical Society, the American Public Health Association, and the Massachusetts Association of Boards of Health; medical officer of the board of health of Cambridge from 1889 to 1909; died at his home in that city, April 16, from arteriosclerosis, aged 68.

Addison Parker Macomber, M.D. New York University, New York City, 1853; formerly president of the Iowa State Homeopathic Medical Society; died at his home in Atlantic, Iowa, April 16, aged 79. The physicians of the city passed resolutions expressing their regret at the loss of a faithful associate, and a man of wise counsel and judgment.

William Harper Barrett, M.D. Washington University, St. Louis, 1864; a member of the Missouri State Medical Association, and a charter member of the Cass County Medical Society; major and brigade surgeon of volunteers during the Civil War; died at his home in Harrisonville, April 17, from arteriosclerosis, aged 73.

John Rayner Richardson, M.D. McGill University, Montreal, 1865; a surgeon in the federal service during the Civil War; a member of the American Medical Association; surgeon to the Lakeside Hospital and to the Sons of St. George; died at his home in Chicago, April 27, from cerebral hemorrhage, aged 67.

Katherine Bohm Leidich, M.D. Woman's Medical College of the New York Infirmary for Women and Children, New York City, 1899; a member of the Harrisburg Academy of Medicine; died in the Harrisburg Hospital, March 24, from acute nephritis following an operation for appendicitis, aged 44.

Elbert S. Miller, Jr., M.D. University of Pennsylvania, Philadelphia, 1869; a member of the Tennessee State Medical Association; for about twenty years president of the Johnson City Board of Education; said to have been the oldest practitioner of that city; died at his home, April 12, aged 68.

Charles Stuart Elder, M.D. Rush Medical College, 1863; a veteran of the Civil War; a member of the school board; for two terms alderman, and in 1872, mayor of Chenoa, Ill.; died at the home of his daughter in that city, April 12, from senile debility, aged 75.

Charles C. Phillips, M.D. St. Louis College of Physicians and Surgeons, 1895; formerly a member of the American Medical Association; a member of the Idaho State Medical Association; died at his home in Lewiston, March 29, aged 42.

John Andrew Steele, M.D. Berkshire Medical College, Pittsfield, Mass., 1866; Homeopathic Medical College of Pennsylvania, Philadelphia, 1858; died at the home of his daughter in Minneapolis, April 14, from cholelithiasis, aged 74.

Eugene J. Chassagne, M.D. University of Paris, France, 1877; Jefferson Medical College, 1893; for eight years a member of the staff of Jefferson Hospital, Philadelphia; died at his home in Washington, D. C., April 7, from paresis.

John Fairfield Moulton, M.D. Long Island College Hospital Brooklyn, 1874; a member of the Maine Medical Association; died at his home in Limington, April 14, from peritonitis, following an operation for appendicitis, aged 61.

Samuel Michael Jenks, M.D. Rush Medical College, 1872; of Madison, S.D.; a veteran of the Civil War; and a member of the first board of trustees of the State Normal School; died in Madison, April 14, from pneumonia, aged 65.

Abraham R. Groves, M.D. Kentucky School of Medicine, 1858; University of Louisville, 1867; for a time dean of the staff of the Louisville City Hospital; died at his home in Louisville, April 17, from nephritis, aged 75.

Isaac Frederick Ingersoll, M.D. Queen's University, Kingston, Ont., 1863; medical officer in the United States Army during 1864 and 1865; died at his home in Regina, Sask., Nov. 10, 1910, from senile debility, aged 71.

Robert Louis Hill, M.D. Rush Medical College, 1864; Hahnemann Medical College, Chicago, 1867; consulting physician to the Fabiola Hospital, Oakland, Cal.; died at his home in that city, April 6, from prostatitis, aged 69.

Gabriel A. D. Brown, M.D. Jefferson Medical College, 1868; a member of the Kentucky State Medical Association; of Harrisonville; died at the home of his son in Louisville, April 15, from carcinoma of the stomach, aged 64.

Herbert Benjamin Hutton, M.D. Trinity Medical College, Toronto, 1902; a member of the Welland County (Ont.) Medical Association; died suddenly at his home in Humberstone, Ont., April 8, from myocarditis, aged 33.

Harry Ross Wallace, M.D. College of Physicians and Surgeons, Chicago, 1891; of Chicago; a member of the American Medical Association; died in St. Joseph's Hospital, Alton, Ill., April 12, from diabetes, aged 54.

Samuel D. Smoke, M.D. Medical College of the State of South Carolina, Charleston, 1859; died at his home in Fort Ogden, Fla., Nov. 13, 1910, from chronic nephritis, complicated by aortic stenosis, aged 73.

George Bayneham, M.D. Manitoba Medical College, Winnipeg, 1908; of Brookdale, Man.; died in the General Hospital, Portage la Prairie, April 10, from injuries received in a runaway accident a week before.

Carl Ludwig Larson, M.D. College of Physicians and Surgeons, Chicago, 1902; formerly a member of the American Medical Association; a practitioner of Butte, Mont.; died in Chicago, April 7, aged 39.

Harriett E. Magee Fox, M.D. Hahnemann Medical College, Chicago, 1871; prominent for many years in philanthropic work in Chicago; died at her home in that city, April 21, from diabetes, aged 68.

Robert C. H. Rademaker, M.D. Hospital College of Medicine, Louisville, 1903; clinical assistant in diseases of children in his alma mater; died in Washington, D. C., April 5, from gastritis, aged 37.

Charles James Joseph Lynch, M.D. Bellevue Hospital Medical College, 1890; died at his home in New York City, April 19, from an overdose of paraldehyd, taken as a sleeping potion, aged 41.

William P. Woodcock, M.D. University Medical College, New York City, 1850; for more than thirty years a practitioner of Spencer, Ia.; died at his home, April 6, from senile debility, aged 84.

Hamil Cato Timmons, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1882; a Confederate veteran, and one of the oldest practitioners of Atlanta; died at his home April 15.

Leander Dixon Rand, M.D. University of Vermont, Burlington, 1888; a member of the Maine Medical Association; died at his home in Fairfield, April 8, from cerebral hemorrhage, aged 48.

James Richard Shapard, M.D. University of Nashville, Tenn., 1874; a member of the Tennessee State Medical Association; died at his home in Nashville, April 18, from meningitis, aged 56.

William Ezekiel Webb, M.D. Jefferson Medical College, 1887; physician to the Chester County (Pa.) Insane Hospital; died at his home in Unionville, April 13, from pneumonia, aged 47.

Percy Ray McLean, M.D. University Medical College of Kansas City, Mo., 1908; of Hunters, Wash.; died in the Monrovia (Cal.) Sanatorium, April 14, from tuberculosis, aged 23.

William R. Endris, M.D. Missouri Medical College, St. Louis, 1882; formerly of St. Louis; a member of the Illinois State Medical Society; died at his home in Brussels, March 31.

Alexander Davis, M.D. Baltimore Medical College, 1892 (license, Tex., Sixth Judicial Board, 1898); died at his home in West, Tex., Oct. 28, 1910, from endocarditis, aged 72.

William H. Hyten (license, Ind., 1897); for sixty years a practitioner of Montgomery County; died at his home in Parkersburg, April 14, from senile debility, aged 87.

John Botsford Sabin, M.D. University of Buffalo, N. Y., 1867; for several years coroner of Kootenai County, Ida.; died at his home in Coeur d'Alene, April 19, aged 65.

Frederick T. Robinson, M.D. College of Physicians and Surgeons, Baltimore, 1893; of Brooklyn, Md.; died in the Johns Hopkins Hospital, Baltimore, April 10, aged 43.

William Carson Wilson (license, Arkansas, 1903); for forty-three years a practitioner of Arkansas; died at his home in Yellville, April 5, from influenza, aged 74.

Arthur Dorval, M.D. Victoria University, Coburg, Ont., 1874; died at his home in Montreal, Que., Dec. 26, 1910, from peritonitis due to a gastric ulcer, aged 58.

Eli Wilson, M.D. Barnes Medical College, St. Louis, 1896; of Puxico, Mo.; died in Hot Springs, Ark., Oct. 15, 1910, from valvular heart disease, aged 43.

Philip A. Austin, M.D. Cleveland University of Medicine and Surgery, 1866; died at his home in Muscatine, Ia., February 13, from pneumonia, aged 76.

Isaac Smith Vreeland, M.D. New York University, New York City, 1876; died at his home in Stony Point, N. Y., April 8, from pneumonia, aged 59.

John J. McElwee, M.D. Washington University, St. Louis, 1863; formerly of Chain of Rocks, Mo.; died at his home in Houston, Tex., April 21, aged 76.

Addison Snively, M.D. University of Wooster, Cleveland, O., 1880; a veteran of the Civil War; died at his home in Cleveland, April 9, aged 66.

Vernon Tuford Chew, M.D. Washington University, St. Louis, 1860; died at his home in Rosenberg, Tex., March 26, from influenza, aged 74.

Thomas J. Solt, M.D. Central College of Physicians and Surgeons, Indianapolis, 1884; died at his home in Mountaintop, Pa., April 3, aged 54.

Joshua M. Fackler, M.D. Pulte Medical College, Cincinnati, 1878; died at his home in Plymouth, O., April 11, from pneumonia, aged 73.

Harry Lloyd Madden, M.D. Medico-Chirurgical College of Philadelphia, 1909; died recently at his home in Mount Alton, Pa., aged 29.

Wesley Jones Burns, M.D. Trinity Medical College, Toronto, 1876; died recently at his home in Caledonia, Ont., aged 57.

R. H. Dyke, M.D. Missouri Medical College, St. Louis, 1878; died at his home in Bellflower, Mo., April 19, aged 57.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

[Contribution from the Chemical Laboratory of the American Medical Association]

TABLETS OF BISMUTH, OPIUM AND PHENOL

W. A. Puckner and W. S. Hilpert

Nearly three years ago[1], a contribution from the Chemical Laboratory appeared in The Journal, dealing with the composition of tablets of bismuth, opium and phenol (carbolic acid). It was there shown that these tablets contained only from 72.65 per cent. down to as low as 12.66 per cent. of the amount of phenol stated on the label.

After publishing these results in detail and waiting a little more than two years, we again examined similar tablets of the same makes, bought in the open market. The results of this second examination were published in The Journal, Dec. 17, 1910. Instead of finding that conditions were better, that the firms had made an effort to market tablets that were true to the label, this examination showed that the phenol-content of the tablets now ranged from 63.53 per cent. down to 12.27 per cent. of the amount claimed.

This second examination also showed that the manufacturers were not sufficiently concerned with the quality of their product to call in any stock which they must have known was untruthfully labeled. In view of this fact, it was thought worth while both to learn the ages of the various tablets that were purchased at the time of, and for the purpose of, making the second examination and also to examine the most recently made tablets put out by the same firms. Accordingly, the identifying marks on each package of tablets examined and which formed the basis of the report of the second paper, were sent to the respective firms with inquiries as to the date of the manufacture of these various specimens. At the same time orders were placed in each case for the firm's most recently made product.

The result of this work is arranged in tabulated form as follows: Table 1 gives the age of the specimens that were used for the second examination; Table 2 compares the composition of tablets as found in the first and second examinations with the composition found in the present (third) examination.

TABLE 1.—AGE OF TABLETS IN SECOND EXAMINATION

Manufacturer	Date of Manufacture	Date of Purchase	Age When Purchased
Hance Bros. & White...	Sept. 17, 1910.	Oct. 27, '10	1 month.
W. S. Merrell Chem. Co.	July 11, 1906..	Oct. 27, '10	4 years.
H. K. Mulford Co.....	Nov. 22, 1909..	Sept. 15, '10	1 year.
Parke, Davis & Co.....	Sept., 1910....	Sept. 15, '10	Under 1 mo.
Sharp & Dohme.......	June 1, 1906...	Sept. 15, '10	4 years.
F. Stearns & Co... ...	August, 1906..	Oct. 27, '10	4 years.
Truax, Greene & Co....	Prior to 1906..	Sept. 16, '10	4-5 years.
H. K. Wampole & Co...	Aug. or Dec.,'08	Oct. 27, '10	2 years.
W. R. Warner & Co....	Aug. 3, 1906...	Nov. 11, '10	4 years.

Strange as it may seem, some of the manufacturers wrote as if they had not known of the former publication of the laboratory's examination.

Wm. R. Warner & Co. writes that it is going to engage the services of a commercial chemist to examine the stock and that it will not offer the tablets for sale until assurance is had that the tablets are true to claim. While it may cause some surprise to learn that this firm must engage outside talent to learn the quality of its own wares, the decision to discontinue the sale of its practically worthless stock is to be commended.

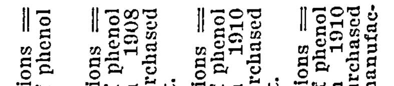
TABLE 2.—COMPOSITION OF TABLETS IN FIRST, SECOND AND THIRD EXAMINATIONS

Phenol Found Expressed as Per Cent. of Amount Claimed

	Specimen Purchased on Market		Specimen Obtained from Manufacturer
Manufacturer	1908	1910	1910
Hance Bros. & White......	21.89	34.19	34.49
W. S. Merrell Chem. Co....	48.89	57.59	68.43
H. K. Mulford Co.........	52.34	63.53	83.18
Parke, Davis & Co........	(a) 70.23 (b) 47.02	46.86	46.83
Sharp & Dohme.........	(a) 72.65 (b) 34.63	53.39	38.14
F. Stearns & Co..........	26.55	23.17	24.86
Truax, Greene & Co.......	13.69	28.09	28.24
H. K. Wampole & Co.....	(a) 46.14 (b) 39.31	53.75	112.64
W. R. Warner & Co.......	12.66	12.27	41.47

The tablets which were obtained direct from H. K. Wampole & Co. and which were found to contain an amount of phenol in excess of the amount claimed were quite different in appearance when received from any previously examined in that they were damp and had a strong odor of phenol. About two months later, the tablets of this batch which remained in the bottle presented a most remarkable appearance in that they were covered with an efflorescence of crystals of phenol. Should these tablets be dispensed on a physician's prescription the possibilities are that the pure phenol would come in direct contact with the tongue and throat and produce painful burns. Of course these tablets are quite unfit for use.

Another important matter brought out is the fact that ready-made mixtures, such as these tablets, may be four or five years old before they leave the hands of the wholesaler. While, in this case, the efficiency of the remedy is not influenced by age, it is a well-known fact that many drugs rapidly deteriorate. If tablets such as these are likely to be four or five years old before they leave the wholesale house, how old will they be before they are dispensed on a physician's prescription? This question is a pertinent one and the answer—which the laboratory's work furnishes—should do much to discourage the prescribing of such ready-made mixtures.



The above presents the findings of the Association chemists in a graphic form and shows the great discrepancies between the claims made for the tablets and the actual facts. The solid black portions represent the phenol-content. In the first column is given the phenol content claimed by the manufacturer; in the second column is shown the actual phenol-content found in the tablets purchased in 1908; the third column represents the phenol-content as found in the tablets purchased on the market in 1910, while the fourth column shows the phenol-content of the tablets purchased in 1910 direct from the manufacturer. Note the excess of phenol in the tablets sent by H. K. Wampole & Co. in filling the order for a bottle of the most recently made products.

SANATOGEN—ITS FOOD VALUE

To the Editor:—Will you kindly tell me whether or not Sanatogen has any food value?

Arch Dixon, Jr., M.D., El Paso, Texas.

Answer.—Sanatogen is said to contain 95 per cent. of casein so that 30 gm. (1 ounce) of this preparation would contain approximately 28.5 gm. of protein, which would yield 117 calories. This is the equivalent in round numbers of one-third of a pint of milk or one and one-half eggs. The same amount of energy would be given by an equal weight of starch or by one and one-fifth as much of flour or other cereals. To present the matter even more graphically, it may be said that $1 worth (4 ounces) of Sanatogen yields approximately no more energy than 6 cents' worth of good milk or 1 cent's worth of ordinary wheat flour. Sanatogen, therefore, like most preparations of this class, while a food, is a ruinously expensive one. The absurdly exaggerated claims regarding it were discussed in The Journal, Feb. 19, 1910, as follows:

"According to the manufacturers, this patent medicine—or food—is composed of 95 per cent. casein and 5 per cent. sodium glycerophosphate. The preparation is advertised very extensively both to physicians and to the laity, on both sides of the Atlantic. In Great Britain it is a 'tonic food;' in this country a 'food tonic;' whether this is a distinction with or without a difference, it is hard to say. The public is told that Sanatogen is a 'muscle builder and a nerve and brain food;' the medical profession, that 'it should not be regarded as a food preparation in the ordinary sense of the term and it is not offered as such to the medical profession. . . .' Many of the claims made for this combination of milk-curd and glycerophosphates are exaggerated and absurd. The following are taken from advertisements, appearing both in this country and abroad:

"The Re-Creator of Lost Health."
"Sanatogen is . . . a rebuilding food."
". . . revitalizes the overworked nervous system."
"Specific nerve tonic action."
"Most reliable and scientific of all nutrients."
". . . *in certain diseases* it exerts a *specific action* which renders it a valuable adjunct to other curative measures."

"In one of the form letters sent to physicians, the makers of Sanatogen opine that 'you have likely noticed' an article that appeared 'in the May issue' of a certain medical journal. The ingenuousness of this intimation becomes apparent when it is known that a few days previous to receiving the letters, the physicians had been the recipients of pamphlet reprints of said article—'With Author's Compliments.'

"That milk curd has a food value no one will deny; that the glycerophosphates of soda have a place in medicine may be admitted; but that a combination of these two products should become at once the summum bonum of medicinal foods is a proposition that will not appeal to the thinking physician."

Correspondence

Fatal Accident from Toy Pistol Means of Securing Sane Fourth Ordinance

To the Editor:—On April 11, a child, aged 7, was playing with another boy, aged 13, and in some manner a toy blank cartridge pistol, which had been loaded with a 22-caliber cartridge, with the bullet whittled down to allow it to enter the bore of the pistol, was discharged, the bullet entering the younger child's back, between the lower ribs and the crest of the ilium. In spite of everything that could be done, even to opening the abdomen in the hope of tracing the bullet, which had been followed from the rear as far as the spine, the child died about thirty-six hours after the accident.

It was found that the toy pistol causing the child's death had been purchased for the celebration of last Fourth of July.

Attorneys, physicians, and business men, together with the press, at once took up the matter of a prohibitive ordinance insuring a "sane Fourth" and April 17 the desired ordinance was passed by the Enid city commission, and the prohibition made to include all forms of explosive fireworks. Some slight objection was made by one or two members of the commission who wanted an exception made in favor of small firecrackers and other so-called harmless fireworks, but several physicians armed with the statistics summarized in The Journal, Sept. 3, 1910, turned the tide; the opposition was withdrawn and the ordinance was passed as drawn.

The firms in the city handling fireworks had agreed to cancel their orders in case an ordinance was passed immediately, and to their fair-mindedness in the matter the result was due in no small measure.

The physicians of Enid have been trying to get such an ordinance passed for two or three years, but were always met by more or less indifference, and by the statement that it would be unjust to the dealers to prohibit the sale of stock already purchased. It took this needless sacrifice of an innocent young life to bring the community and the city government to their senses in the matter, but once aroused they have moved in the matter with a promptness truly commendable, and we hope in the future to have a Fourth truly "sane."

P. A. Smith, M.D., Enid, Okla.

The Round-Ligament Operation

To the Editor:—I believe Dr. J. Clarence Webster and Dr. J. M. Baldy (see The Journal, April 29, 1911, p. 1280) are both behind the times in respect to priority of the operation above named. I saw Dr. Frank Andrews do this operation at Mercy Hospital in 1898 many times, drawing the round ligaments through the broad ligaments and uniting them back of the fundus. Dr. Andrews said that occasionally it might be advantageous to put a small suture from ligaments to fundus when the round ligaments were greatly relaxed.

William J. Thomson, Portage, Wis.

Method of Staining Bacteria

To the Editor:—My attention has been called to the fact that I have not mentioned the staining of preparations for the standardizing of vaccine by the method described in my article on "The Simplified Method of Staining Bacteria," which appeared in The Journal, April 22, 1911, p. 1189.

I have used this method of staining for that purpose all along with the greatest satisfaction in place of Leishman's or Wright's blood-stain recommended by most observers.

Leon S. Medalia, Boston.

Association News

No Genito-Urinary Section Program at Los Angeles

To the Editor:—At a meeting of the executive committee of the Section on Genito-Urinary Diseases of the American Medical Association, held April 20, it was unanimously resolved to hold the first meeting of the Section in 1912.

The committee finds that proper representation cannot be secured at so late a date in June this year.

H. H. Young, Secretary, Baltimore.
William T. Belfield, Chairman, Chicago.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

PUBLIC DOCUMENTS NOT FREE

To the Editor:—You recently mentioned the Public Health Bulletins. Every letter that I have received in reference thereto has indicated that the writer had received the impression from your publication that the bulletins were sent free.

If you can see your way clear to publish a few lines removing that erroneous impression, which causes some disappointment to those who address me, and involves considerable correspondence on the part of my clerks, I shall be obliged.

August Donath, Superintendent of Documents,
Washington, D. C.

Answer.—The language in the editorial referred to, April 8, 1911, page 1039, can hardly be held responsible for the inference that these bulletins are sent free. It is far more likely that this inference comes from the well-known fact that government publications are, to such a large extent, furnished free. The average reader may be excused if he thinks this custom is general, in view of the thousands of tons of speeches and political documents which our representatives and senators send without charge on slight provocation to any of their constituents who may be influenced. For instance, a recent despatch from Washington stated that one senator had shipped two car-loads of envelopes, addressed and bearing his frank, to the largest city in his state, where they were to be filled with copies of his speeches and distributed, gratis, and postage-free to the voters of the state. This enormous mass of literature (?) was distributed for political reasons, and so cost the individual nothing, but will be paid for by the tax-payer. The public health pamphlets on the other hand, were intended only to save life and reduce sickness, and so could not, of course, be distributed free to the tax-payer. A price-list of these documents can be secured from the Superintendent of Documents. Meanwhile political speeches and garden-seeds can be had for the asking, as usual.

QUININ AND UREA ANESTHESIA

To the Editor:—Please give me the technic and other information pertaining to quinin and urea hydrochlorid as a local anesthetic.

E. D. Collett, Mangum, Okla.

Answer.—The technic of anesthesia by quinin and urea hydrochlorid is the same as that by cocain. The injections are used in the strength of from ¼ to 1 per cent. The ¼ per cent. solution is said to be free from the risk of producing fibrous indurations, which sometimes occur with the stronger solution. For application to mucous membranes solutions varying in strength from 10 to 20 per cent. should be used.

The following articles on this subject have been published or abstracted in The Journal.

PIPERAZIN, LYCETOL AND LITHIA IN NEPHROLITHIASIS

To the Editor:—Please advise me as to the value of piperazin and lycetol in nephrolithiasis. Are they of enough value to warrant paying such a fancy price for them? Please advise me if there is anything I can do beyond advising a strict diet, plenty of water to drink, and possibly lithia.

C. E. D., M.D., *Flora, Ill.*

Answer.—Piperazin, lycetol, lithium carbonate and other alkalies are more or less efficient solvents of uric acid and urate calculi in the test-tube; careful experimental work, however, as well as theoretical considerations, demonstrate that the chemical conditions are unfavorable for their solvent action in the tissues and in the urinary passages. Critical clinical observers also agree that these drugs are not reliable uric acid solvents. The most rational and effective, as well as the most economical, treatment of nephrolithiasis consists in the dilution of the urine by drinking plenty of water, prevention of excessive acidity by the administration of alkalies, and limitation of the uric acid progeners in the food by avoidance of meats. It is doubtful whether piperazin, lycetol or lithium salts would add to the efficiency of the treatment. The question of uric acid solvents will probably be discussed in The Journal in greater detail in the near future.

ALCOHOL IN THE TREATMENT OF POISONING BY THE PORTUGUESE MAN-OF-WAR

To the Editor:—It may help Dr. R. S. Lowry, of Fort Lauderdale, Florida [The Journal, April 22, 1911, p. 1213] to know of my experience, during the past seven years at Palm Beach, with the poison of the Portuguese man-of-war. Among the numerous bathers at the above resort, I have had several cases of more or less severe poisoning by this jellyfish, and the only prompt relief that I have obtained has been by bathing the place stung with alcohol 95 per cent. This gives immediate relief, and the continual use of alcohol and water, equal parts, relieves permanently. My theory has been that the alcohol dissolves and neutralizes the poison, as it does in ivy poison. I have tried nearly every external application, but found nothing so satisfactory as the alcohol.

William E. Bullard, Larchmont, N. Y.

The Public Service

Medical Department U. S. Army

Changes for the week ended April 29, 1911.

Glennan, James D., lt.-col., left Army Gen. Hosp., San Francisco, on 30 days' leave of absence.

Kerr, Robert W., lieut., relieved from duty as surg., transport *Sheridan*, on arrival at San Francisco, about Oct. 12, 1911, and will report to adjunct general of Army for further orders.

Bayly, Rozier C., lieut., relieved from duty as trans. surg. *Logan*, on arrival at San Francisco, about Nov. 12, 1911, and will report to the adjutant general of the Army for further orders.

Suggs, Frank, M.R.C., on withdrawal of troops from Ft. Egbert, Alaska, will proceed to Seattle, Wash., for further orders.

Lincoln, H. F., M.R.C., when his services are no longer needed on the transport *Crook* will proceed to Ft. Apache, Ariz., for duty.

Ruddy, Wm. P. J., M.R.C., recently appointed, will proceed to Ft. Myer, Va., for duty at that station.

Hewitt, John M., M.R.C., assignment to U. S. A. T. *Dix*, revoked.

Fisher, H. C., major, left Columbus Bks., Ohio, on ten days' leave.

Deshon, Geo. D., major, orders directing him to proceed to the Philippine Islands, for duty, on July 5, 1911, revoked.

Hewitt, John M., M.R.C., retd. to station U. S. Mil. Prison, Ft. Leavenworth, Kan., from en route to Seattle, Wash., for duty on transport *Dix*.

Griffis, F. C., M.R.C., to Ft. Robinson, Neb., for temporary duty.

Wolven, F. Homer, D.S., ordered to proceed to several posts in Alaska, for duty.

Knox, Howard A., lieut., resignation accepted by the President.

Richardson, William H., captain, relieved from duty at Army Gen. Hosp., San Francisco, and ordered to Ft. Miley, Cal., for duty.

Boak, S. Davis, D.S., relieved from duty at Army General Hospital, San Francisco, and ordered to West Point, N. Y., relieving William H. Chambers, D.S., who will proceed to the Army General Hospital, San Francisco, for duty.

Ferguson, James B., 1st lieut., relieved from active service under the provisions of an Act of Congress March 4, 1911.

Freeman, Chas. E., captain, relieved from duty at Ft. Miley, Cal., and ordered to the Army General Hospital, San Francisco, for duty.

Each of the following-named officers is relieved from duty at the station designated after his name, to take effect at such time as will enable him to comply with this order, and will proceed at the proper time to San Francisco and take the transport to sail from that place on or about Sept. 5, 1911, for the Philippine Islands, and on arrival at Manila will report in person to the commanding general Philippines division, for assignment to duty: 1st Lt. John T. Aydelotte, M.C., Ft. Sam Houston, Tex.; 1st Lt. Harry R. Beery, M.C., Ft. Benjamin Harrison, Ind.; 1st Lt. Joseph Casper, M.C., Ft. Du Pont, Del.; 1st Lt. George W. Cook, M.C., Ft. Douglas, Utah; 1st Lt. Arthur O. Davis, M.C., Ft. Oglethorpe, Ga.; 1st Lt. Joseph W. Love, M.R.C., Fort Banks, Mass.; 1st Lt. Herbert I. Harris, M.R.C., Ft. Snelling, Minn.

Each of the following-named officers is relieved from duty at the station designated after his name, to take effect at such time as will enable him to comply with this order, and will proceed at the proper time to San Francisco and take the transport to sail from that place on or about Oct. 5, 1911, for the Philippine Islands, and on arrival at Manila will report in person to the commanding general, Philippines division, for assignment to duty: Lt.-Col. Guy L. Edie, M.C., attending surgeon, Washington, District of Columbia: Maj. Wm. E. Vose, M.C., Jackson Bks., La.; 1st Lt. Taylor E. Darby, M.C., Ft. McPherson, Ga.; 1st Lt. Ralph G. de Voe, M.C., Ft. Worden, Wash.; 1st Lt. James S. Fox, M.C., Ft. Sam Houston, Tex.; 1st Lt. Glenn I. Jones, M.C., Ft. McDowell, Cal.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended April 26, 1911:

Stoner, J. B., surgeon, directed to proceed to Pittsburg, Pa., and assume command of the service.

Wertenbaker, C. P., surgeon, directed to proceed to Fortress Monroe, Va., and inspect unserviceable property on hulk *Jamestown*.

Schereschewsky, J. W., P. A. surgeon, relieved from duty at Baltimore and directed to proceed to Washington, D. C., and report to Director of the Hygienic Laboratory for duty.

Grimm, R. M., asst.-surgeon, relieved from duty in the Hygienic Laboratory and directed to proceed to Savannah, Ga., and assume temporary charge of the service.

Clarke, F. M., acting asst.-surgeon, granted twenty days' leave of absence from May 6, 1911.

Goldthwaite, Henry, acting asst.-surgeon, granted thirty days' leave of absence from April 1, 1911.

Board of medical officers convened to meet at San Francisco, Cal., April 24, 1911, for the examination of Assistant Surgeon A. J. Lanza, to determine his fitness for promotion to the grade of Passed Assistant Surgeon. Detail amended as follows: Surgeon Rupert Blue, chairman; Passed Assistant Surgeon F. E. Trotter; Passed Assistant Surgeon M. W. Glover, recorder.

Medical Economics

This Department Embodies the Subjects of Postgraduate Work, Contract Practice, Legislation, Medical Defense, and Other Medicolegal and Economic Questions of Interest to Physicians

GOVERNOR O'NEAL VETOES THE ALABAMA OPTOMETRY BILL

The optometry bill recently passed by the Alabama legislature, through a misapprehension as to its intent, has been vetoed by the governor, Hon. Emmet O'Neal. His veto message should be read by all interested in preventing the passage of these bills. Governor O'Neal said:

To the Senate: I herewith return Senate Bill No. 151, without my approval.

This bill proposes legally to organize or establish in this state a new occupation or profession, to be known as optometry, based on the science of optics as applied to the eye.

As I understand it, an optometrist is in reality an optician, and an optician has always been considered a tradesman, and he is not required or expected to have a scientific medical knowledge required by law of the oculist—whose profession authorizes him to medically treat the eye.

Inasmuch as the field of the optometrist constitutes a part of the broad field of the science of medicine, a part already occupied by regularly educated and licensed physicians, known as oculists, it becomes a question worthy of investigation and study as to the wisdom of permitting territory belonging legitimately to one profession to be invaded by persons who are not, and do not claim to be, equipped for membership in that profession. As all know, the eye is a very delicate and important organ of the body. Consequently, to deal with it intelligently there is required a thorough knowledge of not only its optics, but its anatomy, physiology and diseases. While optometrists propose to deal only with the optics of the eye, to draw the line that separates the optics of the organ from its diseases must require a thorough knowledge of everything that appertains to the eye; that is, of its optics, anatomy, physiology and its diseases.

A man who is familiar with only one part of the subject would necessarily often be unable to determine where his domain begins. Just as a physician who understands only the anatomy, physiology and diseases of the eye would not be in a position to deal with its optics, so a person who only understands its optics would not know where its diseases begin. That is, the entire subject seems to be so closely correlated as to render it practically impossible to draw a line of demarcation between its parts, and assign one part to persons who do not claim to study or understand the whole. If this be true, it becomes a serious question as to the good policy of by law authorizing persons to occupy a field, the limits of which they cannot definitely define. A class of men, known as opticians, has long existed. The duties of these consist in grinding glasses and filling the prescriptions of oculists. This relation corresponds with that sustained by druggists and physicians, and it would seem to be the wisest policy to insist that these relations be maintained. To permit an optician to usurp the rights of an oculist, who is at the same time an educated physician, would be quite as irregular as to permit a druggist to usurp the rights of a physician in the treatment of diseases of patients.

I am informed that bills similar to this one have been introduced in many legislatures, inspired perhaps by some large manufacturing establishments for the manufacture and sale of glasses. It is easy to see that conferring a high-sounding title on men engaged in a trade would tend to exaggerate their importance and skill in the minds of the public.

In vetoing this bill I am not depriving opticians or persons dealing in glasses of any rights that legitimately belong to them.

If such a law is enacted it would, in my opinion, be an infringement on the already existing laws regulating the practice of medicine in this state. I therefore recommend that any applicant for the practice of optometry be required to undergo the same examination as that of any specialist who proposes to practice medicine in his selected specialty.

I am informed by physicians of the highest authority and by men who by life-long study have thoroughly acquainted themselves with the eye and its diseases, that the legislation sought in this bill is extreme, and I am also informed by the State Board of Health that only a thoroughly equipped and licensed physician should be permitted to enjoy the privileges intended to be conferred on optometrists by this bill.

It will be noticed that it is intended by this bill that the opticians of the state shall have exclusive control of the officers provided for in the bill, and I am informed that if there is a department created by legislation akin to that sought by this bill it should be placed under the control of the State Board of Health, or of regularly licensed and educated physicians.

A bill similar to this one was presented in 1907 to Governor Hughes of New York, and was vetoed by him on this very ground.

[After quoting from the veto messages of Governor Deneen[1] of Illinois and Governor Harmon of Ohio,[2] Governor O'Neal concludes:]

The eye is too delicate and valuable an organ to be made the subject of any experiment whatsoever; and if there is to be such a science as that of optometry I fear that it is yet too near to its inception to be given the power contemplated in this bill, which is returned to you without my approval.

Emmet O'Neal, Governor.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR

Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Second Weekly Meeting

Causes of Sudden Death (Continued)

Death by Asphyxia

Hanging: Death due to obstruction of admission of air, to pressure on blood-vessels, to injury to nerves or spinal cord. Phenomena of hanging; three stages (Tidy). Postmortem appearances, external and internal. Suspension before and after death. Homicidal hanging.

Strangulation: Manual (immediate) or by ligature (mediate). Garroting. Phenomena of strangulation; four stages (Draper). Post-mortem appearances, external and internal. Accidental, suicidal and homicidal strangulation.

Suffocation: Methods. Accidental, suicidal and homicidal suffocation. Post-mortem appearances.

Drowning: Post-mortem appearances, external and internal. Manner of death. Accidental, suicidal and homicidal drowning. Determination of interval between death and recovery of body.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Arkansas: Regular, Little Rock, May 9. Sec., Dr. F. T. Murphy, Brinkley; Homeopathic, Little Rock, May 9. Sec., Dr. P. C. Williams, Texarkana; Eclectic, Little Rock, May 9. Sec., Dr. G. A. Hinton, Hot Springs.

Florida: Regular, Tallahassee, May 8-9. Sec., Dr. J. D. Fernandez, Jacksonville.

Kentucky: The Armory, Louisville, May 31. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: Regular, New Orleans, May 18-20. Sec., Dr. A. B. Brown, 108 Baronne St.

Massachusetts: State House, Boston, May 9-11. Sec., Dr. Edwin B. Harvey, Room 159 State House.

Mississippi: Jackson, May 9. Sec., Dr. S. H. McLean.

Nebraska: State House, Senate Chamber, Lincoln, May 24. Sec., Dr. E. Arthur Carr, 141 S. 12th Street.

New York: May 23-26. Mr. Harlan H. Horner, Chief of Examinations Division, Department of Education, Albany.

Wisconsin: Milwaukee, May 24-26. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

Utah Secures an Amended Practice Act

Revisions to the Utah medical practice act have been secured providing: (a) that the attorney general shall be ex officio a member of the board of medical examiners; (b) that the board shall consist of nine members so appointed that

---

1. The Journal A. M. A., June 1, 1907, p. 1871.
2. The Journal A. M. A., June 25, 1910, p. 2135.

the terms of three members expire each year; (c) that the minimum number of hours constituting the medical course required of all applicants be 3,500 hours, no specific total being fixed for the various subjects of the medical curriculum; (d) that the minimum requirement of preliminary education shall be a certificate from a first grade high school which shall have included at least two units work in Latin or German, *but that after 1916, each applicant in addition must furnish* evidence of at least one year's work in a college of liberal arts; (e) that the fee for examination be $25.00; (f) that authority be given to the board to revoke the license of any practitioner guilty of unprofessional conduct after proof of such conduct has been secured; (g) that the board be empowered to establish reciprocal relations with other states; and (h) for a definition of the practice of medicine.

"Unprofessional conduct" is defined to mean: (1) offering or attempting to procure or aid or abet in procuring a criminal abortion; (2) the procuring or aiding or abetting in procuring a criminal abortion; (3) the obtaining of any fee on the assurance that a manifestly incurable disease can be permanently cured; (4) the wilful betraying of a professional secret; (5) any advertising naming diseases of or in relation to the diagnosis or treatment of, or medicine for any abnormal or diseased condition of, or pertaining to the organs of generation; (6) all advertising of medicine or of any means whereby the monthly periods of women can be regulated or the menses reestablished if suppressed; (7) conviction of any offense involving moral turpitude; (8) habitual intemperance or gross immorality; (9) lending his name to be used as a physician or surgeon by another person who is not a physician or surgeon; (10) street advertising, soliciting or other public peddling or selling of medical or surgical remedies or appliances in person or by proxy; (11) prescribing any intoxicating liquor to be used as a beverage; (12) prescribing morphin or cocain or other narcotic with intent that the same shall be used otherwise than medicinally or with intent to evade any law in relation to the sale, use or disposition of such drugs; (13) wilful violation of the law in regard to the registration of births and deaths and the reporting of infectious diseases to the State Board of Health.

The definition of the practice of medicine is as follows: Any person shall be regarded as practicing medicine within the meaning of this title, who shall diagnose, treat, operate on, or prescribe or advise for, any physical or mental ailment or any abnormal, mental or physical condition of another, after having received or with the intent to receive therefor, either directly or indirectly, any fee, gift, compensation or other pecuniary benefit, reward or consideration; or who shall hold himself out by means of signs, cards, advertisements or otherwise as a physician or surgeon.

Connecticut Regular, Homeopathic and Eclectic March Reports

Dr. Charles A. Tuttle, secretary of the Connecticut State Medical Examining Board, reports the written examination held at New Haven, March 14-15, 1911. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 75. The total number of candidates examined was 24 of whom 17 passed and 7 failed. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Yale Medical School	(1910)	75.5, 76.9, 81.5, 82.1, 82.9, 85.8, 88.6.
Northwestern University Medical School	(1897)	79.4
Johns Hopkins University Medical School	(1908)	77.7
Tufts College Medical School	(1905)	78.3
Long Island College Hospital	(1909)	77.9
Jefferson Medical College	(1909)	83.2
University of Virginia	(1908) (1909)	84.7; 77.2
University of Toronto, Ontario	(1909)	81.9
McGill University, Quebec	(1899)	76.4
University of Rome, Italy	(1898)	78.8
FAILED		
Maryland Medical College	(1910)	65.8, 66.4
Baltimore Medical College	(1907)* (1909)	67 68.1
College of Phys. and Surgs., Boston	(1907) (1910)	49.4; 57.7

* No percentage given.

Dr. Edwin C. M. Hall, secretary of the Connecticut Homeopathic Medical Examining Board, reports the written examination held at New Haven, March 14, 1911. Only one candidate, a graduate of Boston University, 1909, was examined and he passed with a grade of 93 per cent.

Dr. T. S. Hodge, secretary of the Connecticut Eclectic Medical Examining Board, reports that at the meeting held at New Haven, March 14, 1911, one candidate, a graduate of the Eclectic Medical Institute, 1883, was licensed through reciprocity with New York.

Washington January Report

Dr. F. P. Witter, secretary of the Board of Medical Examiners of the State of Washington, reports the written examination held at Spokane, January 3-6, 1911. The number of subjects examined in was 11; total number of questions asked, 132; percentage required to pass, 75. The examination included the clinical examination of patients in hospital wards. The total number of candidates examined was 75, of whom 51 passed, including 1 osteopath, and 24 failed. The following colleges were represented:

College	Year Grad.	Total No. Examined.
PASSED		
Gross Medical College	(1901)	1
Bennett Medical College, Chicago	(1896)	1
American Medical Missionary College	(1910)	1

Wyoming March Report

Dr. J. B. Tyrrell, secretary of the Wyoming State Board of Medical Examiners, reports the written examination held at Cheyenne, March 7-9, 1911. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75, and not less than 60 in any one branch. The total number of candidates examined was 2, both of whom passed. Five candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Hering Medical College	(1895)	86.6
Creighton Medical College	(1910)	80.8

LICENSED THROUGH RECIPROCITY

College	Year. Grad.	Reciprocity with
University of Colorado	(1910)	Colorado
Denver and Gross College of Medicine	(1910)	Colorado
Chicago Homeopathic Medical College	(1903)	Illinois
Keokuk Medical College, Coll. of Phys. and Surgs.	(1904)	Iowa
Northwestern University Medical School	(1910)	Illinois

Book Notices

MODERN TREATMENT. The Management of Disease with Medicinal and Non-Medicinal Remedies. In Contributions by American and Foreign Authorities. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica, Jefferson Medical College, Philadelphia. Assisted by H. R. M. Landis, M.D., Director of the Clinical Department of the Phipps Institute (University of Pennsylvania). In Two Volumes. Vols. I and II. Cloth. Price, $6 net. Pp. 1830, with 193 illustrations. Philadelphia: Lea & Febiger (1910).

This is a composite work; the selection of authors for the various chapters, however, has been judiciously made and the result as a whole is satisfactory. A short introduction by H. A. Hare discusses the general subject of therapeutics and points out its dependence on and close relations to clinical medicine. H. C. Wood, Jr., in a chapter on "Modern Pharmacology," undertakes the difficult task of presenting the conclusions regarding the therapeutic value and use of drugs drawn from the investigation of chemical structure and from animal experimentation. A classification is made from a therapeutic standpoint and the subject is treated in such detail as to insure its marked practical value.

Ambrose Hunsberger, in a chapter on "Combination of Drugs," gives some valuable hints as to the prescription blank, the prevention of repetition, etc. The various forms in which remedies are to be administered are exhaustively described. In connection with this article as well as elsewhere in the work we regret to see a certain carelessness in regard to the Latin of the prescriptions. Errors in the grammatical endings are frequent, while in places a disregard of the official titles and pharmaceutic spelling is noticeable. Thus we find "Adipis lani hydros," "Acetphenetidinæ," "01. theobromæ," "Adipis benzoinatis," etc.

Tuberculin as a therapeutic and diagnostic agent is discussed by F. M. Pottenger, who gives a high value to the tuberculin therapy, but regards it as only one of the agents to be employed. The tuberculin tests are fully discussed; the method of von Pirquet is regarded by the author as of value in adults if interpreted in the right way. We fail to find, however, any specific directions for its correct interpretation. The vaccine treatment of typhoid fever is not considered by D. Riesman as a decided improvement on the older methods. The discussion on this subject is brought fully up to date. The use of horse serum for the hemorrhage of typhoid is suggested. Excellent detailed directions for the administration of specific serum in the treatment of epidemic cerebrospinal meningitis are given by C. H. Dunn.

"The Treatment of Pneumonia" by F. S. Meara exhibits the influence of experimental pharmacology in an important field of practice. Alcohol, in his opinion, has been much used in this disease without justification; it is never a true stimulant. Strychnin, he thinks, has been much overrated and nitroglycerin is absolutely contra-indicated. The method of thoracentesis is described with great detail. Tuberculosis receives 70 pages from the pen of H. M. Landis. Drug therapy receives attention, but aside from a few recommendations for cough and other symptoms, little credit is given to medicine. Even for cough the teaching of self-control to the patient is emphasized.

Syphilis is well treated by William Gottheil. Much space is given to prophylaxis, but the author is skeptical as to the value of moral advice, good as it may be. The treatment with mercury is described with great detail. Salvarsan is noticed, but the author gives merely his own experience, which seems to have been rather unfavorable to the new remedy. The dysenteries are comprehensively treated by J. L. Rhoads.

The article on "Diseases of the Circulatory Organs," by James McKenzie, possesses unusual merit, not only for the expert handling of a subject in which the advances of modern therapeutics have been so momentous, but also for the light thrown on the principles of therapeutics. The tendency of patients and even of physicians to give the credit of the improvement resulting from suggestion to remedies which are in themselves inefficient is especially noted. Such a tendency is often responsible for the continuance of ineffective remedies in cases in which imminent danger demands the prompt application of energetic remedies in sufficient doses. Again, the reader is warned against the tendency to rely too exclusively on the results of laboratory experiments. For instance, although experiment shows digitalis to be a vasoconstrictor, the author's experience shows that therapeutic doses in man do not raise blood-pressure, but often lower it.

"Diseases of the Blood," by J. C. DaCosta, Jr., receives adequate and satisfactory treatment. The work of Joseph Sailer on "Diseases of the Stomach and Intestines" is excellent. The same is true of the treatment of the other internal organs. The technic of local examination and treatment of the female genital organs is clearly described by B. M. Anspach, who contributes one of the most valuable chapters in the book.

Space will not permit specific reference to all the articles in the excellent work, but so far as we have been able to examine them, they seem well adapted to the needs of the practicing physician. The volumes are well illustrated where the subject permits it. Of special interest at the present time are the colored plates showing the erythema of pellagra

THE MODERN MATERIA MEDICA. The Source, Chemical and Physical Properties, Therapeutic Action, Dosage, Antidotes and Incompatibles of All Additions to the Newer Materia Medica that Are Likely to be Called for on Prescriptions, Together with the Name and Address of the Manufacturer or Proprietor, and in the Case of Foreign Articles, of the American Agent. Second Edition. Cloth. Price, $1.25. Pp. 432. New York: The Druggists Circular, 1911.

This book lists, alphabetically, practically every medicinal product which has been introduced into medicine during the last decade. The sources from which the information has been compiled are chiefly the circulars of the manufacturers. Consequently, the work cannot have the authoritative value that it would have had if it had been subjected to rigid censorship by the editor. The statements of the manufacturers have not, however, been accepted at their face value in all cases. In a considerable number the reports of analyses made in the laboratory of the American Medical Association and, to a lesser extent, those made in the laboratory of the Pharmaceutical Institute of the University of Berlin, have been carefully abstracted by the editor and the results compared with the claims of the manufacturer. In this way the plain truth has been told about many nostrums. While in most cases the therapeutic applications of the medicaments are indicated, the book makes no pretense of being an authority in therapeutics. The amount of information given, as indicated in the subtitle, makes the work an encyclopedia which should prove useful alike to prescriber and dispenser. Physicians, however, who are not excessively confident of their own ability and good judgment in such matters might find it more satisfactory to limit their prescribing of proprietaries to such as are included in New and Nonofficial Remedies.

THE WORK OF THE DIGESTIVE GLANDS. Lectures by Prof. I. P. Pavlov, Director of the [illegible] ie Imperial Institute of Experimental [illegible] V. H. Thompson, Sc.D., M.D., F.R.C.S. ([illegible] the Institutes of Medicine, Trinity Colle [illegible] Edition. Cloth. Price, $3 net. Pp. 266, with 45 illustrations. Philadelphia: J. B. Lippincott Co., 1910.

Those who read the first edition of Pavlov's work will find little difference in the main part of the book between that edition and the present one. The translator has added something here and there to bring the lectures up to date, but it is a striking testimony to the value and thoroughness of Pavlov's work that, notwithstanding the activity in this field of research during the eight years which elapsed between the appearance of the two English editions, so few new facts were discovered to add to his description of the secretory function of the stomach. The motor function, on the other hand, is more completely understood, as a result especially of *x*-ray investigations, and in order to present these facts, the translator has added two new chapters drawn largely from American and English sources. In order to conform to the style of the rest of the book these chapters are also presented in lecture form. One other chapter has been largely rewritten.

The readers of the first edition will agree that the character of the facts presented and the charming style in which they are portrayed gave the book much of the fascination of a romance. Both old and new readers will enjoy the perusal of the present edition in which one of the most important and practical sections in the whole field of physiology is so clearly exhibited.

Medicolegal

Adjudications and Prior and Subsequent Conditions as Evidence of Mental Capacity

The Supreme Court of Indiana had, in Taylor vs. Taylor (93 N. E. R. 9), a case where a woman 63 years of age was stricken with apoplexy, July 12, 1899, made a will July 3, 1900, was declared of unsound mind and incapable of managing her estate on a complaint filed January 6, 1906, had a second stroke of apoplexy in July, 1906, and died in January 1907. Unsoundness of mind at the time the will was executed was claimed, and the petition, answer of the clerk and judgment of the court of 1906 were offered in evidence, and excluded.

In holding that there was no error in such exclusion, the Supreme Court says that it cannot perceive that the evidence was so clearly competent or so material, that, if given, it could have had any effect or influence in determining the question of the mental capacity of the woman when the will was executed, when there was direct evidence to the point.

It cannot be doubted that much latitude in point of time, both before and after the transaction under inquiry, is allowable in determining the question of soundness or unsoundness of mind. The reason for the rule is apparent. The consistency or inconsistency of acts or declarations, differences in conduct towards family, relatives, and friends, and differences in habits of life at different times, if they exist, are relevant to, and sometimes highly indicative of, conditions of mind, and therefore competent for the purpose of determining that question, when they are of such character as to denote the mental condition. In some states the statute authorizes the inquiry in lunacy to be extended to a time anterior to the inquiry itself; but the Indiana statute does not authorize a retroactive inquiry to be made, or status fixed, though this court recognizes the prima facie status fixed by the adjudication, and holds that, even though a will is executed after an adjudication of unsoundness, mental capacity may be shown.

Whilst large latitude should be allowed in all such proceedings, and whilst there is no agreed limit of time within which the prior or subsequent condition is to be considered, the circumstances of each case in the very nature of things ought to control, and the discretion of the trial judge, though reviewable for abuse, ought to have weight. The question in such cases is necessarily one of relevancy. The inquiry must be sufficiently near in point of time to aid the jury in determining the mental condition at the time of the execution of the will.

The court knows as a matter of common knowledge that sane people become of unsound mind; therefore there must be some point of time when they thus become. And it knows that persons of unsound mind may have intervals of such lucidity of mind that they are competent to execute wills; hence the fact that a witness has testified that one is of sound mind at one time is only remotely, if at all, affected by the fact of the same person five and one-half years later filing a petition asserting such person to be of unsound mind, and incapable of managing his or her own estate, at that time. The adjudication is only prima facie evidence of mental incapacity.

Liability for "Waste" in Use of Property for Small-Pox Hospital

The Supreme Judicial Court of Massachusetts holds, in Delano vs. Smith and others (92 N. E. R. 500), that the use of property for a small-pox hospital may, under certain circumstances, constitute what in law is known as "waste." The latter it defines as an unreasonable or improper use, abuse, mismanagement, or omission of duty touching real estate, by one rightfully in possession, which results in its substantial injury—a violation of an obligation to treat the premises in such manner that no harm be done to them, but that the estate may revert to those having an underlying interest undeteriorated by any wilful or negligent act.

The plaintiff in this case was a holder of a mortgage on property which the defendants, acting as members of the board of health of the city of Everett, leased from the owner, after he had given the mortgage, "to be used as a contagious disease hospital." The plaintiff claimed damages, in the nature of waste. The jury fixed his damages at $1,800, but the trial judge ruled that there could be no recovery, which the court holds was not necessarily so.

It is the commonly accepted view, the court says, that small-pox is a contagious disease, spread through the instrumentality of germs, which, although invisible to the naked eye, are perniciously active and capable of causing loathsome and often fatal sickness. In Commonwealth vs. Pear, 183 Mass. 242, is a statement of the judicial notice which the court will take of the horrors of small-pox. From the agreed facts the jury would have been warranted in finding that this building was filled in every nook and crevice with the microscopic germs of this dreaded disease. This might have been found to constitute a material change in the qualities and condition of the house with reference to the purposes for which it was intended to be used, such as to constitute a definite injury.

Inoculation with germs of glanders was held to be a "bodily injury" in H. P. Hood & Sons (Corp.) vs. Maryland Casualty Co., 206 Mass. 223. Sowing the seeds of noxious weeds was restrained as waste in Pratt vs. Brett, 2 Madd. 62. Impregnation of a building with the indiscernible but vital germs of a dangerous malady is closely analogous to the sowing of seeds of deleterious plants, and may be in its effect far more injurious. It may be in fact even more harmful than to tear down or remove a part of the building. It is in principle the same general kind of injury as the more familiar instances of waste. The possibility of germination of the disease germs which, it might have been found, were deposited through the action of the defendants within the house in question was or might have been found to be waste, unless it was shown that they could be removed by disinfection or otherwise, without material physical change in the building, so as to make it as safe for residence as before.

A case like this one should be submitted to the jury under instructions which would permit the plaintiff to recover the material diminution in the value of his property for every valuable use among ordinarily intelligent men arising from the occupancy for a small-pox hospital, provided the jury were satisfied that it was not reasonable and proper to let the building for this purpose, having reference to the probable effects on its future growing out of the presence of disease-producing conditions, in view of the existing state of the art of disinfection or other way of rendering it healthful, and excluding all sentimental or fanciful notions affecting only its reputation.

Testimony of Attending Physician Inadmissible in Will Case

The Supreme Court of North Dakota holds, in Auld vs. Cathro (128 N. W. R. 1025), that, the privilege of secrecy attaching to all information acquired by a physician from a patient in attending the patient professionally, in a proceeding contesting the probate of an alleged will of a deceased patient, the testimony and opinion of the latter's attending physician as to her mental capacity, based entirely on information derived from her statements or his observations while treating her professionally and for the purpose of such treatment, were properly excluded. The court says that while this question has not heretofore been passed on by it, and while some courts, notably Minnesota, Iowa and Missouri, have held under certain circumstances that such testimony was admissible under statutes somewhat similar to that of North Dakota, the court thinks the better rule is as above stated. New York, Wisconsin, California, Utah and other states hold such evidence inadmissible; holding that the privilege is personal with the patient, that it applies in testamentary matters, and cannot be waived by the heirs and personal representatives.

Neurasthenia and Movable Kidney.—Movable kidney is proved to be a cause of neurasthenia by the following facts: 1. There is no doubt about the very great frequency of movable kidney in neurasthenic patients, male and female. 2. When these movable kidneys are supported by a proper belt great relief is experienced. 3. Nephropexy cures neurasthenia. Not one relapse has been observed in 150 cases.—*C. W. Suckling,* in the *Practitioner.*

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Fifth Annual Meeting, held at Albany,
April 18-19, 1911

(Continued from page 1285)

President's Address: Medical Teaching and State Board of Medical Examiners

DR. C. STOVER, Amsterdam: An evolutionary movement originating within the medical profession has for some years been directed toward the elevation of medical education in the United States, and the last report to the American Medical Association by the Council on Medical Education was distinctly in the line of advancement. It was not marked by excessive tenderness toward the weak institutions, and fairly indicated the relative strength and weakness of the various medical colleges. The Council cannot greatly regret the appearance of the Carnegie report, for, having been criticized for its somewhat advanced position taken last year, by comparison the Council will be generally considered moderate, and its work in the future rendered easier. The medical schools that have the best laboratories and hospital facilities will attract the best prepared students, and it is equally true that the institutions having inadequate means of instruction will be distinguished by the inferiority of their students. It is at this point that the State Boards of Medical Examiners have abundantly justified their existence. The state has assumed the right to pass on the competency of the graduates of the medical colleges. They touch this problem at three points: (1) the preliminary educational requirements; (2) the facilities of the medical schools; (3) the examinations for licensures. The future of these boards will be marked by increasing importance and responsibility, for on their action more than on any other agency will these problems depend for their evolution. While this is fully appreciated nominations by this society for medical examiners will be among the weightiest duties to be performed. With the increasing importance of laboratory work, it does not require great far-sight to anticipate examinations on laboratory methods, in order to guarantee fully equipped physicians for practice. It is not unlikely that a national board may ultimately be evolved that will unify the chaotic practice of the various states. Is it not clear that if a curriculum of study is to be standardized in the medical schools, it will be equally necessary to have a standard of preliminary training in order to teach with any degree of efficiency? If so, then the entrance examination will be relied on to stop on the very threshold the ill-prepared students. If one were to venture a forecast of the future, it would be that a revolution is not impending, but that the intervention of the state, encouraged by advanced medical opinion, will increase the importance of medical examining boards, that higher and uniform standards of admission on entrance, and more rigid examinations for licensure will eliminate the unfit, and the colleges that best provide the equipment for education will survive, and those that are inadequately equipped must go to the wall. This seems inevitable.

Operations for Adherent Retrodisplaced Uteri by Shortening the Round Ligaments

DR. L. BROUN, New York: After the abdomen has been opened for pelvic conditions, the preference given by operators for retaining the retroverted uterus in an anterior position has been usually some intra-abdominal operation. The operations giving the best results are those in which the strongest part of the ligament is utilized. The Alexander operation, the operation of Gilliam, and also the Simpson operation all do this. The Peterson operation, with some slight modifications, has become so satisfactory in my hands that I have practically discarded other methods. It is for this reason, and because it seems to be little known, that I bring it before the society. The several steps of the operation as I carry them out are as follows: A horizontal incision after the manner of Pfannenstiel is made, but lower down in the area of the growth of the parts. The length of the cut need not be over two and a half inches long. The fascia is divided horizontally and dissected free from the muscle above and below. The recti and pyramidali are now separated, and the peritoneal cavity is entered. Through this opening in the abdomen adhesions can be severed, diseased tubes or the appendix can be removed, and all ordinary pathologic conditions dealt with. Having completed the necessary work in the abdomen, and before closing the incision, the fat in one angle of the wound is dissected free from the fascia in the direction of and up to the external abdominal ring, which is easily located by palpating the pubic spine. This dissection is quickly done with a few snips of the scissors. The skin is retracted beyond the ring, which is readily exposed to view. The round ligament is grasped and withdrawn until the reflexion of the peritoneum comes well in view. This is not stripped from the ligament. If preferred, the fascia can be split up for a short distance, making the ready picking up of the ligament easier. The external abdominal ring of the opposite side is exposed in the same manner, and the ligament is withdrawn, as in the corresponding side. Before anchoring the ligaments in the new position, I retract the edges of the abdominal wound to be sure that no loops of intestines lie over the fundus of the uterus, which generally will be found to be in admirable position. The ligaments are now stitched to the pillars of the ring with chromic catgut or silk, as may be preferred, and the abdominal wound is closed. While drawing out the ligament from the canal, I have found it of value to use for that purpose clamps in which the sharp edges of the serrations have been filed off and the edges also rounded. If ordinary artery clamps are used, the sharp teeth lacerate and cut through the ligament, causing much annoyance, and at times embarrassment. With a flat file the sharp serrations on old discarded clamps can quickly be taken off and at the same time the edges rounded. In dressing the wound after the completion of the operation, full pressure should be applied over the site of the operation to secure close approximation of the separated parts.

DISCUSSION

Dr. H. P. Jack, Canisteo: For the last ten years I have been doing operations for retroflexion of the uterus. In regard to the operation Dr. Broun has brought before us, I can see several objections which have occurred to me in the use of the Alexander-Adams operation. The ilio-inguinal nerve comes through the canal and is frequently injured and pressed on in any shortening of the round ligament, and although I do not do this operation myself, I have seen a number of cases in which the patients have suffered much pain in the region of the inguinal canal, much more pain than from the retroflexion. For that reason, I think Dr. C. H. Mayo has discarded the operation which he originated himself and in which he shortened the ligaments through the inguinal canal by bringing the forceps down and dragging the ligament through the canal. He has given up that operation entirely, and does the Noble operation of fastening the round ligament behind. That operation, he tells me, has been very successful. After ten years' experience with the Gilliam operation I cannot commend it too highly. Patients operated on by this method do not have pain afterward, and with the modification that has now been made we have an ideal operation. I have had a number of these patients go through labor, and the uteri are still in position. I think it has all the advantages of the Peterson operation, it is simpler of performance, and less liable to give pain in the inguinal canal, and requires less dissection.

Dr. L. Broun: I can only suggest that Dr. Jack try this operation, and he will be so pleased with its simplicity and the excellent position of the uterus afterward that I am sure he will do just as I have done, adopt it exclusively.

Diagnosis and Surgical Indications of Duodenal Ulcer

Dr. J. T. Pilcher, Brooklyn: It is impossible to differentiate duodenal ulcer from uncomplicated ulcers of the gastric outlet in some cases. The purest type of symptom-complex is evidenced by duodenal ulcer. There are four cardinal symptoms: chronicity, periodical exacerbations, peculiar pain, and pain relieved by the ingestion of food. In this paper I analyze 156 cases with reference to the cardinal symptoms named. The confirmatory conditions are obtained by analysis of the stomach contents. The hyperacidity of gastric secretions must be considered, and the existence of latent cases is not to be overlooked. There is no ground for conflict between the surgeon and physician in this field of work. The symptoms indicating operation are hemorrhage, stenosis, tumor, and intractability.

DISCUSSION

Dr. Alexander Lambert, New York: After twelve or fifteen years of pain and constant recurring discomfort and disability which such a condition brings about, these patients are glad to go to a surgeon and be relieved. Those are as much surgical cases as are the stenoses of the pylorus or ulcers of the stomach that have formed cicatrices and a more or less contracted or hour-glass condition. A question that is constantly referred to me is what should the medical man do to a young man or person who comes into his office who shows this symptom-complex for the first time? If in a healthy young person who has pain two or three hours after eating, which is relieved as soon as food is taken, and in which by gastric analysis the physician finds distinct hyperacidity, he is generally convinced in his own mind of the probability of duodenal ulcer. After a three days' test of no meat or blood-forming content in the food, one may or may not find occult blood in the stool. Should such a patient be sent to a surgeon for operation? I cannot settle this question from my own experience. Some years ago, I saw such a patient who gave that symptom-complex for the first time, and while quietly lying in bed suddenly bled to death from one large hemorrhage. A better care of the individual patients will be given by both medical men and surgeons if we can settle in our minds what should be done with the early single cases of duodenal ulcer, or those which present the syndrome which justifies us in considering they have duodenal ulcer.

Dr. Elliott P. Joslin, Boston: The average duration of cases of duodenal ulcer before operation is from twelve to thirteen years. What is the average duration of patients who have been subjected to gastro-enterostomy? That is still *sub judice*. We do not know how long these patients are to get on comfortably with that artificial opening. Undoubtedly patients in the class referred to by Dr. Pilcher should be operated on. It is the duty of medical men, whenever they advise operation for the relief of duodenal ulcer, to qualify their advice by saying that the operation shall be done by a man who has had considerable experience in gastric surgery.

Dr. Nathan Jacobson, Syracuse: The question of diagnosis was presented to me about two weeks ago when I was called to see a case of duodenal hemorrhage. The patient, a man of 49, was in an extremely low condition, with the sudden appearance of duodenal hemorrhage. Melena was very profuse; the hemoglobin percentage was nearly 40; the red blood-count a little over 2,000,000. This case presented a series of manifestations so different from what I had seen before, that I could not but consider that we were dealing with more than a simple duodenal ulcer. The first thing that stared me in the face in regard to the diagnosis was the absence of all previous gastric manifestations. This man had never had gastric distress and none of the characteristic manifestations portrayed in the paper. His temperature ranged from 101 to 102 F. While there was a loud endocardial murmur, it was not the hemic murmur we should get from simple loss of blood. It was accentuated. I found petechial spots, and the question arose as to whether we were not dealing with some other condition than duodenal ulcer. A blood-culture was made and a pure culture of pneumococcus was found. There was a case in which the blood-infection showed its first disturbance as duodenal hemorrhage. Once before I have seen intestinal hemorrhage which showed itself first with the symptoms of acute appendicitis as the first manifestation, a purpuric condition, a condition in which we have the appendix with other evidence of intestinal hemorrhage in its region, and subsequently hemoptysis, renal hemorrhage, and purpuric spots, and the first evidence of trouble in that case was intestinal hemorrhage. To those who have seen duodenal ulcers occur in the course of burns I will say that we may think of an acute case of duodenal hemorrhage, due to the pouring out of toxins in the duodenum and irritating processes there, and I want to emphasize the necessity of studying cases of acute hemorrhage and acute conditions and whether or not they are cases for operation. Certainly this case was not one for operation, and its subsequent course justified that conclusion.

Dr. A. E. Chase, Tarrytown: I recall the case of a boy who had been seen by physicians in New York and a number of diagnoses made. He finally came to Tarrytown, and a number of diagnoses were likewise made there. He was brought to the hospital in a moribund condition. He had general septic peritonitis, and I endeavored to do what I could for him. I made a rather large incision, and found the signs of septic peritonitis with considerable pus. But back of that the intestines were matted together by the firmest adhesions I have ever seen, these adhesions being so strong and dense that they could not be torn but had to be cut. In the midst of them was a sinus communicating with an old duodenal ulcer, passing down to the middle of the abdomen and up again to the spine. That sinus had been there for a long time. This boy had had duodenal ulcer for three years; it had perforated, and gave him general septic peritonitis, which caused death.

Dr. A. McFarlane, Albany: No man can tell beforehand what one must do in the individual case. But the important thing that the Mayos have brought clearly to our minds is that a great many of these patients who are relieved are not neurasthenics or nervous dyspeptics, but are suffering from serious anatomic lesions. Whether it is best to operate immediately, or to try local medical treatment in such cases, is a matter to be decided in each individual case.

Dr. I. Adler, New York: While in rare cases gastric ulcer will heal perfectly, duodenal ulcer never does, and the chances of doing irreparable harm are much greater there than in gastric ulcer. I believe that whenever duodenal ulcer has been diagnosed, operation should be decided on at once. It is only a question of time in my mind when operation should be recommended, and I would guide myself always by the appearance of the occult hemorrhage. If there is more or less occult hemorrhage, then I would not delay operation very long, but advise that it be done early.

The Bladder and the Prostate

Dr. John F. Whitbeck, Rochester: It has been estimated that at least one-third of all men after the age of 40 or 50 have enlargement of the prostate, and it is just as certain that hypertrophy of this gland or increase in size from any cause, whether simple or complex, involves the bladder in difficulties. If a patient can be persuaded and taught to lengthen gradually the intervals of urination within the limit of reason, much better control will be obtained with or without the aid of the catheter and patients should be as careful and deliberate as possible while passing urine in order the more completely to expel some portion of the residual fluid. Prostatectomy is rational and offers a complete cure when the individual has no serious organic disease, but is sound or may be made so. Experience shows conclusively that a man in fair health may be cured surely without danger. Contrast for a moment the entire relief afforded by the removal of the prostate when it is enlarged enough to act as an obstruction and a state in which the gland is allowed to remain and the lateral lobes to grow larger, while a middle or third lobe is formed and acts as a ball valve to close the urethral canal, although it lets a catheter pass easily. It is not the frequent desire and necessity to urinate, or the mere use of the catheter from which one shrinks and seeks relief, but the risk of infection, of cystitis, or calculus or pyelitis, or abscess of the prostate, or traumatism from the use of various instruments and the progress from bad to worse.

SYMPOSIUM ON SALVARSAN

Indications for Salvarsan in Syphilis

Dr. S. Pollitzer, New York: Every patient with active infective lesions of syphilis should receive a dose of salvarsan, every individual with extensive gummatous or ulcerative lesions should receive a dose of salvarsan. The effect of salvarsan on such lesions is in general so marked, so prompt, that in justice to our patients we owe them this treatment which so greatly shortens the period of the local treatment. Patients in whom important structures, like the eye or the throat, are involved, should receive salvarsan, as also those with painful lesions of the bones or of the throat and syphilitic cachexia. In these cases the effect of the drug on the constructive metabolism is most striking; a gain in body weight of from 10 to 15 pounds within a fortnight has been observed repeatedly. Individuals with syphilis complicating pulmonary tuberculosis should also receive salvarsan. In these cases the tuberculous process is aggravated by administration of mercury and iodid, and the fear of further damaging the patient's lungs makes it difficult to treat the syphilis properly. Infants with hereditary syphilis should receive salvarsan in minute doses. Here, again, we have the prompt antisyphilitic effect of salvarsan aided by its tonic effect on metabolism. This drug is also useful in an early stage of tabes with pains or sphincter symptoms. While we cannot expect to restore degenerated nerve tracts, the work of Erb and Nonne has made it seem probable that in early tabes there are still active syphilitic foci in the cord, and it seems likely that salvarsan will at least exercise an inhibitory influence on the course of the disease. In the rare cases of oversensitiveness to mercury on the one hand, or of resistance to the effect of mercury on the other, the patients should be treated with salvarsan. Patients who, notwithstanding a thorough course of mercury, show a positive Wassermann reaction, even in the absence of visible lesions, should receive a dose of salvarsan. In the present state of our knowledge a positive Wassermann reaction must be regarded as evidence of an active focus of syphilis. In several individuals who had received a four or five months' course of salicylate of mercury injections in doses up to 5 grains, a persisting positive Wassermann reaction was promptly changed by an injection of salvarsan.

Action of Salvarsan on the Wassermann Reaction

Dr. Howard Fox, New York, presented a tabulated list of thirty-four cases in which salvarsan had been used, and drew the following conclusions:

1. It is difficult at present to draw general conclusions, owing to the great discrepancies in the results of various observers.
2. These discrepancies are partly due to the different methods of injection and to the different stage of the disease in which the injections were given.
3. The results of a single injection given by either the intravenous or intramuscular methods are, as a rule, rather unsatisfactory from the serologic standpoint
4. Repeated injections seem to have given better results and offer a more hopeful outlook for the future.
5. The action of salvarsan on the Wassermann reaction is, in general, analogous to that of mercury.
6. The effect on the Wassermann reaction is much less favorable than on the clinical manifestations of syphilis.

Therapeutics of Salvarsan

Dr. S. J. Meltzer, New York, laid special stress on the scientific principles which form the basis of Ehrlich's experiments in contrast to the use of mercury, which is a remedy hit on by chance. He described the steps by which Ehrlich evolved salvarsan and the brilliant results that have been obtained, and stated his belief that this discovery may be the means of raising therapeutics to the dignity of a science. This article will be published in full in The Journal.

Treatment of Syphilis with Salvarsan

Dr. John A. Fordyce, New York: This paper presents an analysis of the clinical and serologic results obtained in the treatment of 175 patients with this disease with salvarsan. Salvarsan gives more rapid and brilliant results in this class of cases than is seen from the administration of the classical drugs. It is possible that there is here a different strain of organisms more easily influenced by salvarsan than by mercury and potassium iodid. The lesions heal rapidly, a decided increase in weight occurring within two weeks, and the temperature often becoming normal. In advanced disease of the nervous system no benefit was noted from the administration of the drug, but in several cases of early tabes, in one of paresis, in endarteritis of the base of the brain, and in several cases with persistent headache most gratifying results were obtained. In this series of cases there were six relapses, all after treatment with a single dose. They are periosteal lesions in a case of malignant syphilis, plantar and palmar syphilis, mucous membrane lesions and acute unilateral optic neuritis and iritis. Failures were encountered in advanced tabetics and paretics, and in five cases of hereditary syphilis, but three of the latter it is hardly fair to class as failures, since the dose was inadequate. In only one case were by-effects noted which have given any anxiety, namely, convulsions and hemiparesis three days after an intramuscular injection of 0.2 gm. alkaline solution to a child 7½ years old with an extensive gummatous infiltration of the nose and upper lip. The child made a good recovery, and the lesions for which it was treated healed rapidly.

Technic and Methods of Administration of Salvarsan

Dr. Homer Swift, New York, described the method of preparing the salvarsan solution and its employment.

A Few Plain Truths About Salvarsan

Dr. W. S. Gottheil, New York: Salvarsan is valuable in certain cases as an *additional* weapon in our armamentarium, but it does not accomplish the marvels attributed to it. It does not cure any more than does mercury. It is powerful in combating symptoms. Symptoms of the persistence of syphilis appear more *frequently* after treatment with salvarsan than after treatment with mercury. Individuals recently infected are the only ones in whom its efficacy must be estimated. Mercury is still the antisyphilitic for general use. The latest advice from high places is to use salvarsan first, and then to go back to mercury. Cases of idiosyncrasy in which mercury cannot be borne are not so frequent as some would have us believe since the discovery of salvarsan. Salvarsan has been efficacious in the early type of syphilis. The symptomatic effects are equal to those of mercury and sometimes fail. Salvarsan is as useless as mercury in late cases. It is useful in persistent lesions in mucous patches, and in cases not permitting of long medication.

By-Effects of Salvarsan

Dr. James Winfield, Brooklyn: The by-effects are local, organic and general. The local effects are pain, infiltration, sloughing, necrosis, especially with the subcutaneous method of injection, swelling of the lymphatic glands in the neighborhood, scarlatiniform eruption, icterus, herpes zoster and urticaria. Among the organic effects are pulmonary embolism and pneumonia, cardiac and circulatory disturbances, hemorrhagic nephritis and acute necrosis of the convoluted tubules. There are no serious effects on the gastro-intestinal tract. Affections of the cerebrospinal system seem to increase after its use, also ocular involvement and oral effects, which are often transitory. The vital organs should be carefully examined before this remedy is used for any deviation from the normal.

Discussion on Salvarsan

Dr. George Henry Fox, New York: To those who imagined that syphilis was to be forever cured by one dose of salvarsan, and that thereafter mercury will be of value on account of its historic interest, the disappointment has been severe. Even those who have witnessed beneficial results of the remedy, or the numerous and speedy reliefs which have occurred, have been disappointed in a milder degree. While salvarsan has proved a disappointment and in some respects has not yet and probably never will fulfil the high hopes its discoverer intended, it must be admitted that in many cases it has proved to be a remedy as efficacious in its action as it was brilliant in its inception. From what I have observed in private practice and hospital experience, I am convinced that it is a remedy which in certain cases is able to accomplish what no other remedy or method of treatment has done. While I agree with Dr. Fordyce that salvarsan has accomplished what mercury has never accomplished, at the same time I heartily concur in the assertion made by Dr. Gottheil that the disappearance of the symptoms is by no means indicative of a cure of syphilis.

(To be continued)

TENNESSEE STATE MEDICAL ASSOCIATION

Seventy-Eighth Annual Meeting, held at Nashville, April 11-13, 1911

(Concluded from page 1287)

Fractures of the Tibia and Their Treatment

Dr. P. F. Eve, Nashville: I have treated many of these fractures and have had a number of others under observation; in not a few instances I have seen ununited fractures which demanded operative interference. In some of these cases the interposition of the soft parts prevented union, while in others the inability to maintain the fragments in coaptation caused a like result. I have come to the conclusion, therefore, that there are some varieties of fractures of the tibia which call for an open method of treatment. I base this conclusion on the following facts: 1. Should non-union occur from the interposition of the soft parts, and an operation be required after waiting the requisite length of time for union, the very nature of this operation results in a much greater shortening than would have occurred had the operation been performed at the time of the injury. 2. The time required for union in such cases is twice as long. 3. The physical condition of the patient is not nearly so good as soon after the receipt of the injury, his general health having suffered in the many weeks which have elapsed in the effort to accomplish healing of the fracture. 4. The anatomic and cosmetic appearance is not so pleasing

Report of Case of Pellagra

Dr. E. H. Jones, Murfreesboro: In this case the patient lives in the country, appears well, and is working and has been doing so all fall and winter. The treatment consisted of arsenic, iron and strychnin, the arsenic being pushed to tolerance.

DISCUSSION

Dr. J. M. King, Nashville: There have been forty or fifty cases of pellagra in and around Nashville, and I have seen a number of them. The treatment has been climatic, together with the use of iron, quinin and strychnin. I have not pushed the arsenic too much. Moderate doses of arsenic are sufficient, with the very best of food and nursing, with probably bismuth or some of its preparations for the diarrhea.

Dr. J. P. Runyan, Clarksville: Has menorrhagia been a prominent symptom in any of the cases? In two cases I have seen that symptom was pronounced.

Dr. W. Litterer, Nashville: It is the general consensus of opinion that pellagra is contracted through the intestinal tract—that it is some kind of intoxication. Whether it is produced by the food that is ingested or by some bacterium, we do not know. Torrance and McAlester have given salvarsan intravenously in three cases of pellagra with marvelous results.

Dr. J. Overton, Nashville: It is proper to employ tonic treatment for a week or so, but unless decided improvement is shown, some more radical procedure should be resorted to, such as direct transfusion. Cole has obtained a remarkable percentage of recoveries in severe cases of pellagra by transfusion.

Dr. W. Frank Glenn, Nashville: I do not believe that good corn meal will ever produce pellagra, but I am inclined to believe that the disease is communicable.

Dr. L. L. Sheddan, Knoxville: I know of two cases of pellagra in which menorrhagia was a symptom.

Dr. B. J. Rash, Nashville, narrated a case of pellagra in which menorrhagia was a symptom.

Dr. C. N. Cowden, Nashville: I treated a patient for two or three months for infection of the skin, but later a diagnosis of pellagra was made. One diagnostic symptom of pellagra is extreme redness of the tongue.

Dr. M. C. McGannon, Nashville: A young girl had been under my care for two years, and I was unable to account for the inflammation of the vagina which was so intractable to treatment. The condition of the patient steadily progressed until now she has developed all the symptoms of pellagra without, however, any skin eruption.

Reform in Public Schools

Dr. O. Dulaney, Dyersburg: There is need of reform in public schools with reference to hygiene and sanitation. Medical inspection of school children is of great importance, as are also the frequent inspection of buildings by a sanitary officer, and the need of law governing school buildings, and the necessity for medical representation on the state board of education.

The Physician and the Public

Dr. John A. Witherspoon, Nashville: Physicians are in a measure public men, in that they should be the guardians of the health and lives of the people. A physician should stand for everything that is right and uplifting in his commonwealth. His standing in his community should be such that his influence is great and widespread. Belonging to a profession of highest ideals and greatest of responsibilities, in which his opportunity to do good is as great, if not greater, than the ministry, the people have a right to expect a great deal from him. At the same time, they owe a great deal to the physician and should uphold his hands in every way. It is high time that the press, law-makers and people should recognize the fact that the medical profession is the most self-sacrificing in the world; and quit this idle talk of doctors' trusts and all other equally fallacious and untrue statements which only retard the efforts of physicians in the public interest and give to the enemies of mankind a weapon to be used to retard progress and keep from the people the wonderful and life-saving methods which modern medicine offers in the way of preventing disease and insuring that development, mentally and physically, so necessary to the welfare of mankind and good citizenship. Physicians have been subjected to charges of all kinds of crimes and misdemeanors by means of pamphlets circulated by an alien, who suddenly is so much in love with our people that he rushes to their rescue from the north as a representative of the National League of Medical Freedom—whatever that is. I understand that it is composed of the "patent-medicine" manufacturers and others who have been the vampires that sucked the blood of our people so long that they have grown arrogant and dictatorial to the extent that they assume to themselves all the virtue and wisdom of the age and ruthlessly and falsely make charges against the medical profession. Our duties to the public do not end here, but to see that none but safe, moral and competent physicians are permitted to enter the profession. To practice medicine is a very sacred and grave responsibility and the people have a right to expect protection. How can this be done? In two ways: First, by insisting that none but high-grade, well-equipped medical schools for the training of the young men be tolerated; second, by passing such laws by the legislatures that none but moral and well-qualified doctors can be licensed to practice. The passage of good laws and the appointment of strong and competent men to enforce them would soon rid this country of charlatans and ignorant pretenders and strike the death-blow to quacks and venders of nostrums, whose stock in trade is the cupidity and ignorance of the people. If there is any creature any lower than he who traffics in the ills and afflictions of his fellowman, or he who withholds any remedy or treatment that might alleviate human suffering or assist in any way to save human life, it has never been my fortune to meet him. We are misunderstood and often accused of selfish motives when we raise our voices in protest against fads or harmful practices by which individualism and often life is sacrificed on the altar of ignorance.

Acute Inflammatory Glaucoma

Dr. Walter Dodson, Gallatin: Iridectomy is the greatest of all primary operations for glaucoma, but after the operation has been done and the pain and increased tension continue, or should we have a recurrence of the disease, I would not further mutilate the iris by doing a second or third iridectomy, but would do a cyclodialysis. This operation has fallen into disrepute as a primary operation, unless the eye be blind before operation, and then it seems to be the ideal operation. Enucleation is reserved as the last resort, but we find many persons who have been neglected until the eye is blind, and the eye-ball or some parts of it are undergoing a stage of degeneration.

Typhoid Fever

Dr. Thomas Weaver, Nashville: Two outbreaks of typhoid fever in an institution were traced to bacillus-carriers. These outbreaks serve to emphasize several points that may well be remembered. First, the question of bacillus-carriers is one of very great importance, and should always be borne in mind in tracing the source of infection in an outbreak of typhoid fever. Second, the possibility of this danger should be considered in the employment of cooks and other culinary employees, not only in private families, but especially in institutions. Third, it should not be forgotten that the presence of Eberth's bacillus in the stools of bacillus-carriers is by no means constant, and repeated examinations are frequently necessary for its detection.

Practical Laboratory Work for the General Practitioner

Dr. N. Evans, Nashville: Gastric diseases do not receive the attention from a scientific standpoint by the general practitioner which they deserve. They are very frequent, occur for the most part among the better classes, and in a large proportion of the cases are relieved by proper treatment. In many cases it is absolutely essential, in order to make a correct diagnosis, to examine the stomach contents by means of the chemical tests for hydrochloric acid and the organic acids. It is the duty of the teachers of microscopy and allied subjects in medical colleges to make the students see clearly the difference between the laboratory procedures which have simply an educational value and those which have an immediate practical importance. In the latter every man should be so thoroughly trained that he is master of them, can perform them with absolute assurance, and can trust his own findings in, for instance, the recognition of tubercle bacilli, the malarial parasites, and urinary casts. I am satisfied that many physicians graduate from medical colleges without the practical experience in these simpler methods which they ought to have. I believe the plan is most satisfactory where two physicians are associated together in practice, where one can do the greater part of the necessary laboratory work. In most cases the younger men who have more recently worked in the college laboratories will be better fitted to do that part of the work.

The Disease and the Man

Dr. W. B. St. John, Bristol, gave a condensed history of physicians who are discoverers of diseases which bear their names, giving incidents in their lives, their best-known works, under what circumstances their contributions to medicine were brought about, where they were born, what good they did, and how they are remembered and the debt of gratitude the profession owes them.

The Duty of the Country Physician to the Mother and Child

Dr. Howard C. Curtis, Algood: Every mother should be told how to care for her baby, no matter what her circumstances or environment in life; the poorer and more unfortunate mother should have special attention to enable her to better care for her offspring. She should, if possible, nurse her child, and be taught the proper care of the infant's eyes, its mouth and skin, and that it should have a daily bath; that the clothing should be light and cool; that it should have plenty of outdoor exercise; fresh water to drink instead of paregoric and laudanum; that it should have regular habits, and also that it should have regular hours to nurse. A good many other things—feeding, etc.—should not be neglected.

Salvarsan and the Wassermann Reaction in Sixty Cases of Syphilis

Dr. W. Litterer, Nashville, drew the following conclusions:

1. The consensus of opinion now is that a single injection has in favorable cases approximately the same results as a four or five months' treatment with mercury.
2. Salvarsan seems to be of particular value in malignant precocious syphilis, in threatening destructive processes, and in cases that are refractory to mercury.
3. There seems to be no uniformity between the disappearance of the Wassermann reaction and in the improvement of the patient.
4. In a number of instances relapses could be detected by the Wassermann test before clinical symptoms manifested themselves.
5. More favorable results can be expected in a beginning tabetic showing a distinctly positive Wassermann reaction than in one in which a slight reaction appears.
6. In the majority of instances administration by the extravenous (intragluteal) route should first be instituted, since it is the safest method. Should the patient not become Wassermann-negative, the intravenous route may be resorted to.
7. In my series, after a single injection, 35 per cent. resulted in a negative Wassermann reaction in six weeks' time. Out of this number 15 per cent. showed a positive test in three months, while an additional 6 per cent. recurred two months later.
8. A final opinion as to the permanence of its action can only be given after a lapse of several years, during which time both clinical manifestations and Wassermann reactions must be carefully observed.

Treatment of Syphilis

Dr. W. F. Glenn, Nashville: After many years' experience with various preparations of mercury, I feel sure that we can hope for less good from proto-iodids than from any other preparation. I would not willingly abandon entirely the use of a remedy, such as mercury, which has been a sheet anchor for almost 400 years; at the same time I regard salvarsan as a great addition to the therapeutics of syphilis, and truly a boon to humanity.

Injuries of the Head

Dr. D. Eve, Jr., Nashville: There are three prime indications in the surgical treatment of fracture of the base, and these are asepsis, relief of compression, and drainage. In case a fracture communicates with the nose, the nostrils are sprayed with mild antiseptic solution, gently dried and packed with sterile gauze, the packing should not be very tight, the idea being to filter all the air reaching the seat of fracture. In the middle fossa, first place a little piece of sterile cotton in the canal of the ear, then wash the whole outer ear with green soap and sterile water, then remove the cotton and douche the canal with warm normal salt or boric acid solution and insert gauze loosely into the canal. Fluff gauze is placed on this, and retained with a bandage. Compression is relieved by the decompression operation and lumbar puncture. If the fracture involves the anterior or the middle fossa, the operation consists of subtemporal trephining in the temporal region with drainage. Cushing advises trephining on both sides; with fracture of the posterior fossa, the operation should be occipital decompression with drainage. Patients with dilatation and fixation of both pupils, deep coma, rapid rise of temperature and stertorous breathing are rarely benefited by operation. We often see patients in whom the coma is not profound after the accident, but later grows gradually or suddenly worse, showing signs of increased intracranial pressure, then operation with drainage will save many of them. Lumbar puncture should be done for diagnostic and therapeutic purposes. It is a positive means of distinguishing subdural hemorrhage from supradural hemorrhage; also it diminishes the intracranial tension. Ransohoff uses repeated lumbar puncture in cases in which the coma is not profound, and claims that this takes the place of the decompression operation.

Appendicitis With Concurrent Typhoid Fever

Dr. W. D. Sumpter, Nashville: In a case of appendicitis in which the symptoms of typhoid did not appear until after operation, the distal end of the appendix was distended with thick pus and was so near rupture that after the operation, in handling it, pus oozed spontaneously from its wall. The proximal end appeared normal except for adhesions.

Vaginal Hysterectomy

Dr. J. A. Gaines, Nashville: The vaginal method of hysterectomy is indicated for carcinoma of the cervix of corpus uteri in any case in which there are not such glandular involvements as preclude operation by any method. For non-adherent fibroids not too large to be delivered by the vagina the operation is indicated. Either general myofibroma, subperitoneal or submucous tumors are easily dealt with in this way. This method is also greatly superior in dealing with prolapsus uteri after the child-bearing period is passed, as it lends itself more readily to the plastic work required to support cystocele and rectocele, one or both of which are always found in association with this condition. The vaginal route offers ready access to the ovaries or tubes which may be removed, resected, or the tube removed, leaving any part of the ovary desired, with as careful plastic resection as the abdominal route will permit. No vaginal celiotomy for any cause should be done without a thorough preparation of both vaginal and abdominal fields. In any vaginal hysterectomy, conditions may arise or be found making it most desirable to finish by the abdominal route, using the combined method, which is preferred by some as a regular procedure.

Other Papers Read

The following papers were also read: "Lacerations of the Deep Urethra," by Dr. J. J. Waller, Oliver Springs; "Pellagra Associated with Uncinariasis," by Dr. J. W. Breeding, Ravenscroft; "When Does the Gonorrheic Cease to be Infectious?" by Dr. C. F. Anderson, Nashville: "Surgery of the Intestines," by Dr. J. H. Carter, Memphis; "The Relationship of Food to Disease," by Dr. E. A. Timmons, Columbia; "Technic for Intravenous Injection of Salvarsan," by Dr. E. T. Newell, Chattanooga; "Sarcoma of the Stomach," by Dr. J. Overton, Nashville; "Oblique Inguinal Hernia," by Dr. D. Eve, Nashville.

House of Delegates

The House of Delegates by resolution commended the work of Senator Owen, of Oklahoma, in his effort to promote the passage of national legislation for the establishment of a National Department of Health, and urged each member to interview Senators Taylor and Lee of Tennessee, with a view to enlisting their support in the passage of the bill.

The association adjourned in a body and appeared before the Committee on Ways and Means of the Senate, and urged the passage of the following bills: a model vital statistics bill, a state hygienic laboratory, and the medical inspection of school children. The senatorial committee, after listening to speeches from several members of the medical profession, in less than thirty minutes, recommended the three bills for passage. A similar hearing was granted the profession before the Committee on Ways and Means of the House, where the opposition to the bill on the medical inspection of schools was violent, but it is thought that the three bills will finally pass.

AMERICAN

Titles marked with an asterisk (*) are abstracted below.

Boston Medical and Surgical Journal

April 20

1 *Scoliosis with Marked Structural Change and Rotation. R. Soutter, Boston.
2 Acute Postoperative Dilatation of the Stomach. E. W. Lee, New York.
3 *Id. R. T. Morris, New York.
4 An Analysis of Forty-Six Cases of Prostatectomy. L. Davis, Boston.

1. **Scoliosis.**—Soutter pleads for the more thorough treatment of stiff scoliotic cases, in many of which absolute correction of the curve seems practically impossible. Simple, flexible and uncomplicated curves are not considered in this paper. He urges that the general condition must be improved. Developmental exercises should be done systematically, all exercises taken in a position which brings a minimum strain on the deformity. This may be accomplished best by suitable machines for the purpose under skilled assistants. It is accomplished also at home to a less extent. The flexibility of the spine in all directions should be increased; having attained this, and improved the general physical condition, the state of mind and endurance of the patient is much better. The periods for eating, for rest and for work should be established with regularity. Correction of the deformity is started during the development and flexibility treatment; later it is carried to a greater extent and the points of greatest deformity attacked more vigorously. Exercises are adjuncts in the treatment but will not take the place of especially adapted corrective machines and apparatus applied to the deformity. The advanced case of scoliosis should not be trifled with.

In addition to the appliances in which the patient is treated for from three to four hours each day, the patient should have apparatus to wear when about, and other apparatus to wear when in bed. The amount of apparatus and the treatment necessary varies with the patient. The apparatus worn at night is made after a certain amount of correction has been attained. The night and day apparatus must be carefully adapted to the improvement. Corrective jackets follow the other treatment. The patient is kept recumbent and successive corrective jackets applied either from remodeling the cast or from newly applied jackets. Following from two to four months of corrective apparatus, a retentive apparatus is applied, maintaining the full correction in a comfortable way and the patient is allowed to go from two to six months, when further treatment may be instituted, according to the requirements.

Excellent results were obtained in 182 cases treated by Soutter. Sixty-five, or one-third, were greatly corrected; ninety-seven were improved; in twenty, while the patients were benefited in strength, endurance and health, their curves were not improved. Considering the degree of rigidity as a factor in those that were greatly corrected, thirty-nine were of slight degree of rigidity, none was extremely rigid. In the cases with marked improvement, thirty-two were slightly rigid, twenty-eight were rigid and thirteen were extremely rigid. Of the patients who were improved, three were slightly rigid, eleven were more rigid and eight were extremely rigid.

3. **Acute Postoperative Dilatation of the Stomach.**—In cases of acute gastric dilatation Morris advises placing the patient on the abdomen, inclined a little to the right side. That will mechanically compress the dilated stomach and unkink the duodenum. He would wash out the stomach every hour or two if necessary with the stomach tube. That allows the postural mechanical resource to become more effective, and it takes away saprophytic poisons.

9. **Psychogenetic Convulsions.**—A woman, aged 23, gave a history of attacks of *petit mal* from her second to her fourth year; she had *grand mal* attacks, from four to twenty a month, from the fourth to the twenty-third year, with hallucinatory attacks, and compulsive ideas. Treatment by suggestion produced immediate and almost complete relief for a period of eleven months.

10. **Pepsin and Diastase in Urine.**—Goodman is convinced that no diagnostic aid is to be sought in the amount of pepsin or diastase in the urine. He disclaims all value for the determination of the ferments in the urine, *per se.*

20. **Bone Transplantation.**—By an accidental discharge of a gun, Ross' patient was shot in the middle third of the right leg, the shot carrying away part of the tibia and fracturing the fibula, and completely destroying the anterior tibial group of muscles in the middle third of the leg. A posterior splint, well-padded, was applied with plaster-of-Paris encasing the foot and the thigh. The father refused to allow the foot to be amputated. Infection followed and for a while threatened the life of the patient. When it became evident that union was not going to take place voluntarily, Ross began to look about for some means of relief and finally decided to try Huntington's suggestion of using the fibula in a somewhat modified form. An incision was made about 6 inches in length midway between the tibia and fibula in the lower part of the upper third and the upper part of the middle third of the leg. The muscles were carefully dissected away and the fibula was cut about 2 inches below its articulation with the tibia. The adjacent borders of the two bones were denuded of periosteum and fastened with nails which were removed ten days later. The tibia and fibula had become united by callus below the seat of the fracture so required no care; except for a pointed projection, there was a space of at least 1½ inches between the bones. One fragment of dead bone in part filling this space was removed and the cavity curetted and cleansed as well as possible. Considerable infection followed with breaking down of scar tissues. Despite this, in four weeks' time the union was fairly firm. The patient walked on the foot about seven months after operation. The limb is about 1¼ inches short, due in part to shortening allowed to bring ends of bone nearer together and, in part, to imperfect growth since accident, as the left foot is about ¾ of an inch shorter than the right. Shortening does not seem to have increased since operation. The gap between the ends of the tibia is completely filled with new bone.

25. **Puerperal Septic Infection.**—The query propounded in the title of this paper is answered by Polak as follows: Each case of postpartum or postabortal infection must be studied individually, and an accurate diagnosis made on the clinical and bacteriologic findings, before any treatment is instituted. Nature is competent in the majority of instances to localize and circumscribe the infection. Operative procedures should be avoided if possible, and are not indicated unless there is demonstrable evidence of intrapelvic or abdominal inflammation, necrosis or suppuration. Curettage, douches and examinations during the acute stage, break down barriers and open avenues for the further dissemination of sepsis to the myometrium, parametrium and adjacent tissues, and the danger from curettage increases with each month of pregnancy. Enormous pelvic and abdominal exudates may disappear without operation, and in time enlarged ovaries, tubes, etc., may assume their proper size and function, and so long as the patient's general condition improves, no surgery is advisable. All operations are attended with less risk after the acute stage of the infection has subsided, and an exact diagnosis is more easily made at this time. After the uterus is thoroughly emptied, the pelvis should be left absolutely alone, and every effort should be made to support the patient and increase the natural blood resistance.

Vaccine therapy has a definite but limited field in the treatment of puerperal septic infection. Inoculation with autogenous vaccines will promise prompt results in staphylococcus and colon bacillus infections, but in streptococcus poisoning vaccine treatment is unreliable and is of value only when the virulence of the germ is attenuated, or when Nature has already developed a phagocytic defense.

Extraperitoneal drainage of local foci should be elected when possible, either by incision just above Poupart's ligament or by posterior vaginal section, and when this is impossible, because of an inability to determine the exact anatomic relations of the local focus, an exploratory laparotomy is justifiable in order to make an exact diagnosis, and to determine on the safest route for drainage. Operative interference, in the acute stage of sepsis, is only indicated in general purulent peritonitis, postabortal pelvic peritonitis, infected tumors in or near the genital tract and uterine rupture, when said rupture has occurred in the course of labor and has been handled outside of a well-managed maternity, and finally, thrombophlebitis is a conservative process on the part of Nature to limit the infection, and any form of pelvic manipulation only tends to break down and separate parts of these thrombi, extending the infection to the more remote parts, and thus jeopardizing the patient's life.

26. **Extra-Uterine Pregnancy.**—In this series of cases, fifty pregnancies were on the right side, forty-four on the left, one double, and the others were not recorded. Sixty-six cases were diagnosed as ectopic, fourteen (three diagnosed fibroids and four with a question of appendicitis) as pelvic tumor, with a question as to the cause, but no mention of ectopic pregnancy, three as appendicitis, four as twisted pedicle or extra-uterine pregnancy, seven pelvic inflammation (pyosalpinx, hydrosalpinx, etc.). In some cases gall-stones and perforations were considered in making the diagnosis, one patient being sent for gall-stones only and gall-stones were found. Five did not give a diagnosis, though most of them gave a clear history and were recommended to the hospital for surgical pelvic trouble. In summing up the points in differential diagnosis, Graham says: Briefly, one gets (1) the history of a normal menstruation missed, usually but a few days (fourteen), possibly weeks; (2) there are more or less severe colicky pelvic or abdominal attacks, alternating irregularly with periods of perhaps normal health, (3) accompanying these painful attacks or immediately following them is a scanty, intermittently prolonged flow; (4) examination reveals pregnant changes in genital tract, smooth, velvety mucous membrane, softened cervix, enlarged uterus, a tumor, tender, localized and not large, before rupture. After rupture, tender and large without a prolonged history to account for its size, and no history of infection. Vomiting, chills and fever with fainting and collapse attend the severer cases. Careful history development and careful physical examination should leave fewer unmade diagnoses in extra-uterine pregnancies.

49. **Pyloroplasty.**—Hough thinks that his modification of the ordinary pyloroplasty might prove effective by furnishing a permanently large pylorus and could be done with greater ease than Finney's operation and in some cases in which a Finney operation would seem to be impracticable. The objection to it is that it is an open operation and cannot be done with clamps, but in a patient prepared properly and guarded by gauze, this is not to be considered seriously. It is the sliding of a wedge of stomach wall into the spreading duodenal part of the incision. This is accomplished by making a Y-shaped incision and suturing it into a V-shaped form. An incision 4 or 5 inches long, 2 or 2½ inches of which are on the duodenum and 2 or 2½ inches on the stomach wall, is made as in the ordinary pyloroplasty, after which the stomach end of this incision is carried for a short distance in two diverging directions, making the arms of the Y. These arms diverge at any required angle—the more obtuse the angle the greater the width of the new pylorus. By bringing the apex of the wedge along the spread duodenogastric incision until it can be attached to the other end of the incision, the wedge gradually becomes wider and the result is a V instead of a Y.

52. **Probable Cause of Acute Poliomyelitis.**—Corn and cornmeal are here associated etiologically with anterior poliomyelitis. Grossman points out that there were more cases of infantile paralysis in Iowa in 1910 than ever before in any one year. There was much more spoiled cornmeal and spoiled corn consumed by the people of the state the same year than ever before. In examining the diagrams of the towns where the disease was prevalent last year, the diagrams being drawn by expert physicians, and showing the residences of those who were stricken by the disease, Grossman could not conclude that the plat of the towns showed any evidence whatever that the disease is contagious. Here and there in different parts of the towns persons were affected, or perhaps in some families there may have been two persons thus affected. Therefore, he asks whether it does not look very much more as if some grocery might have had sour cornmeal, or spoiled corn in some other form, and the people in different parts of the towns and country used it.

64. **Milk and Milk Serums.**—Gudeman is convinced by the results of his experiments that if a milk-supply is to be protected for the benefit of the public health, real pasteurization is not sufficient, and commercial pasteurization, much less so. Sterilization is a much better safeguard (home sterilization)—even with is effects on the milk, change in character as to taste and possible effect on ratio of digestibility. It is fully as necessary to protect and watch sterilized milk

as raw milk, and pasteurization, *per se*, Gudeman says, is only protection for the benefit of manufacturers and vendors of pasteurizing machinery. Cleanliness is the most necessary, most essential and most efficient requirement in the production and distribution of milk. Milk should be watched and protected against contamination of all kinds, from cow to consumer, both inside and outside of the containers used in its distribution. Raw milk, spoiling and becoming "sour" within a short time, condemns itself and the acid-forming germs are the safeguards, indicating to the consumer the age, that is, the actual condition of the milk. Acid-forming germs do not increase the toxicity of the milk; just the contrary. Pasteurized milk, unless as fresh as the raw milk, can be and often is the cause of an infinite number of troubles, the absence of "souring" being a false indication of security. Sterilized milk is a safe milk, being free from living germs and free from toxic substances due to their decomposition, although also free from the living active germs necessary for a complete and perfect digestion of the milk, under normal conditions. Clean, raw milk comes first; thereafter Gudeman's choice is sterilized milk, fresh or canned, but if one is compelled to use commercially pasteurized milk of unknown origin and uncertain age, he would practice self-protection and boil the milk before consumption. Commercial pasteurization is a poor makeshift, a premium offered for the distribution of old, dead, stale and often unwholesome, dirty milk. Pasteurization, he asserts, deteriorates clean milk.

65. **A Sanitary Milk-Supply.**—Instead of contending and temporizing with improper pasteurization, or pasteurization of improperly procured milk, or improper care of pasteurized milk, Black would demand and work for pure, clean milk. Work with the dairyman to have him produce it, work with the general public to keep it so after receiving it, and last, but not least, occasionally remind our own profession of the important place they have in this battle.

67. **Unappreciated Baths.**—The effervescent bath and the continuous bath are discussed by Fantus and their more frequent use is urged.

70. **Prevention of Hemorrhage.**—Since June 15, 1909, Pettit has administered autogenous vaccines to eighty-four patients with pulmonary tuberculosis. Of these eighty-four, sixty-five were under observation two months or longer. It has been observed during the past nineteen months, that hemorrhages have been less frequent than before. The class of patients, diet, exercise, sleeping conditions, supervision, etc., were practically the same as in preceding years; the only new factor introduced into the treatment was the administration of autogenous vaccines. It has occurred to Pettit that possibly the injection of vaccines against the organisms of mixed infection had a protective action against tissue dissolution and hence against hemorrhage. In all cases considered in the class receiving vaccines at least three doses of vaccine were administered. In thirty-two cases vaccines were made from organisms isolated from the sputum. In twenty-two cases vaccines were made from organisms isolated from the blood-stream. The percentage of hemorrhage in individuals receiving vaccines was approximately ⅓ of that in persons not receiving vaccines. The percentage of hemorrhage in those treated with vaccines made from organisms isolated from the sputum is very much lower than it is in individuals treated with vaccines made from organisms isolated from the blood. The results shown in patients showing hemorrhagic tendencies are suggestive of the protective effect of the vaccines. Pettit regards the administration of autogenous vaccines justifiable in a large number of cases as a protective measure in the same way typhoid inoculations are used in the prevention of typhoid.

87. **An Unusual Powder Smoke Fatality.**—On Jan. 16, 1911, a blast was set off in the Gunnison Tunnel at 2:30 in the afternoon. The men at work retired to a safe distance, as they had done several times daily for many weeks, to allow the smoke to clear away. In less than three days nine of a bunch of thirteen men who inhaled the smoke died of acute pulmonary trouble. A like disaster had never been heard of by engineers in charge of the work. There were many old miners among the men who were working in the tunnel, and none of them had ever known of a similar occurrence. An analysis of the circumstances by Gilbert and Whitman seems to show that the cause of the deaths was the inhalation of nitrous fumes, particularly of ntirogen tetroxid or dinitryl, N_2O_4, and that these fumes were formed by the action of the electric power current on the smoke from the burning powder. Although no record can be found of the formation of dinitryl in this manner, sufficient has been written on the subject to show the entire reasonableness of this explanation. When nitric acid is exposed to the air or is brought into contact with organic matter or metals it is partly volatilized and partly decomposed, and the oxids of nitrogen are formed, particularly nitrogen tetroxid, N_2O_4, also called dinitryl or nitrogen peroxid. The simpler and less poisonous form of this gas is NO_2 or nitryl. It will be shown that nitryl, NO_2 was present in the smoke. Only the action of the electric current could then be necessary to convert it into its allotropic or nascent form N_2O_4, or dinitryl. Johnson cites briefly the history of each of the thirteen cases. He calls attention to the possibility that some of the rapidly fatal cases of pneumonia to which miners are subject may be due to dinitryl.

98. **Blood-Pressure in Tuberculosis.**—A complete study was made by Emerson of the status of the blood-pressure in tuberculosis. He says that hypotension or subnormal blood-pressure is universally found in advanced pulmonary tuberculosis, in which condition emaciation may play a part in its causation. Hypotension is found in almost all cases of moderately advanced tuberculosis, or in early cases in which the toxemia is marked, except when arteriosclerosis, the so-called arthritic or gouty diathesis, chronic nephritis, or diabetes complicate the tuberculosis and bring about a normal pressure or a hypertension. Occasionally the period just preceeding hemoptysis or during hemoptysis may show hypertension in a patient whose usual condition is that of hypotension. Emerson emphasizes that hypotension should be sought for as carefully as it is the custom at present to search for pulmonary signs. Hypotension when found persistently in individuals or families or classes living under certain unhygienic conditions should put us on guard aganst at least a predisposition to tuberculosis. Hypotension, when it is present in tuberculosis, increases with an extension of the process. Recovery from hypotension accompanies arrest or improvement. Return to normal pressure is commonly found in those who are cured. Continuation of hypotension seems never to accompany inprovement. Prognosis, Emerson found, can as safely be based on the alteration in the blood-pressure as on changes in the pulse or temperature.

Emerson believes that the causes of low blood-pressure in tuberculosis are probably primarily a toxic action on the vasomotor center in the medulla, allowing of a vasoparesis or stimulating an active vasodilatation. and secondarily, progressive cardiac atrophy or degeneration. Rapid heart action is a usual and necessary sequel to low blood-pressure and will, if extreme, aggravate the hypotension by the very act of its shortened diastole. It has been suggested, but not proved, that lack of vagus inhibition owing to pressure by enlarged bronchial lymph nodes and presence of sympathetic excitation from similar or reflex causes such as pulmonary or gastric irritation, are responsible for the tachycardia and hypotension. Marked vasomotor irritability is recognized as a frequent phenomenon in pulmonary tuberculosis and is supposed to result in tachycardia and hypotension, but it is not easy to see exactly what is meant by this term unless a certain functional instability, for which we have no proof of any definite local cause. The result of hypotension in tuberculosis or in any other condition is insufficient capillary pressure, more or less venous stagnation and insufficient nourishment, with resulting atrophy or degeneration of the essential organs of the body.

Emerson emphasizes that the treatment of tuberculosis in all its stages should take into consideration the need of assisting in every way the return to normal blood-pressure, first by relieving the relaxed vessels of the load put on them during the vertical position or exercise, and later by assisting the heart by abundant nutrition, moderate exercise and the stimulating effect on cardiac and vascular tone of cold fresh air, to meet the extra work put on it by the loss of vascular tone. Thus will the heart be able to maintain its normal bulk and strength or even to gain from the atrophy or small size of the early disease, to a normal size, so that the brain, kidneys, lungs and body at large may be properly nourished, until the disease is arrested and the toxic products of the tubercle bacillus are no longer distributed from the site of the lesion.

101. **Effects of Internal Secretions on Tumors.**—Briefly summarizing their evidence, the authors point out that: (1) removal of certain glands (i. e., thyroid, thymus and testes) appears to decrease the susceptibility to cancer; (2) removal of single glands or combination of glands in immune animals leads to lessened immunity to cancer; (3) extracts of thymus, thyroid, spleen, pancreas, pituitary and testes on injection tend to increase immunity against cancer and extracts of certain other tissues produce like effects; (4) similar extracts, on injection in cancerous organisms, alleviate pain, reduce tumors or even cause them to disappear; and finally (5) their results, combined with those of other observers, tend to the conclusion that many tissues contain some common element, possibly of the nature of a hormone, which is capable of producing immunity.

103. **Pathologic Anatomy of the Human Thyroid Gland.**—The classification of the thyroid diseases made by Marine and Lenhart is as follows:

I. Normal thyroid.
II. Active hypertrophies and hyperplasias (goiter).
  1. Developing from the normal thyroid.
  2. Developing from the colloid gland (goiter).
III. Colloid glands (goiters).
IV. Regeneration (hyperplasias).
V. Atrophies:
  1. Premature atrophies:
    (a) of obsesity.
    (b) of cretinism.
    (c) of myxedema.
  2. Senile.
VI. Degenerations:
  1. Hyaline.
  2. Amyloid.
  3. Calcareous, etc.
VII. Inflammations:
  1. Acute thyroiditis.
  2. Chronic thyroiditis.
VIII. Tumors:
  1. Benign.
    (a) Fetal adenoma.
    (b) Simple adenoma.
  2. Malignant.
    (a) Carcinoma from fetal adenoma (carcinoma simples).
    (b) Glandular carcinoma.
    (c) Sarcoma.
    (d) Endothelioma.
IX. Complications:
  1. Hemorrhage.
  2. Cyst formation.
    (a) From hemorrhage.
    (b) From fetal adenoma.

Thus, there are nine major anatomic divisions, which represent different physiologic or pathologic stages. The first four divisions, viz., normal thyroid, active hypertrophy or hyperplasia, colloid gland and regeneration, are physiologic. The remaining five divisions are properly designated as pathologic and are only the generally accepted groupings common to all body tissues.

104. **Water Drinking.**—Three experiments are described by Rulon and Hawk in which the topic under investigation was the influence of copious water drinking between meals on the excretion of chlorids. The subjects were young men ranging in age from 22 to 29 years. Each experiment was divided into three periods, a preliminary period during which nitrogen equilibrium was attained through the feeding of a uniform ration of low water content, a water period during which the uniform ration was supplemented by the drinking of large volumes of water between meals, and a final period in which the conditions of the preliminary period were in force. In two of the experiments there was a pronounced increase in the output of chlorids in the days of added water intake with a return to normal during the final period. This augmented excretion of chlorids is interpreted as indicating that the large volume of water ingested during this period has markedly stimulated the secretion of gastric juice. The excess hydrochloric acid thus passed into the intestine has been reabsorbed and appears, at least in part, in the urine as ammonium chlorid. The main bulk of the increase in the chlorid excretion they believe to have originated in this way. The flushing of the tissues and the stimulation of protein catabolism brought about by the copious water drinking may have been contributing forces in causing the increased output of chlorids observed. In one experiment there was a small increase in the chlorid output on each day of increased water ingestion followed by a pronounced rise in the output on the first day following the water period. Neither the flushing properties of the water nor its stimulating efficiency as regards protein catabolism or gastric secretion offers a satisfactory explanation for the high chlorid concentration observed on the day following the period of copious water drinking.

105. **Digipuratum in Heart Disease.**—Digipuratum has now been in use at the Massachusetts General Hospital for over a

year, and more than 180 cases of primary heart disease or secondary cardiac involvement have been treated with it. The effect on the urinary output has been very prompt in most instances. There was not a single case of vomiting or diarrhea. In fact, the vomiting of a number of cardiac patients at entrance was promptly stopped by digipuratum. Cumulative poisoning has never been observed. One of the early patients, a boy of 16, was given 106 tablets in six weeks: at no time was there any suggestion of digitalis poisoning. In one or two instances the house officers were made uneasy by sudden drops of 40 or more beats in the pulse-rate, but no disagreeable consequences followed in any case. It must be borne in mind, however, that digipuratum is a digitalis preparation, and that as such it must necessarily have a tendency to produce poisoning by cumulation. In the case of digipuratum this tendency is merely much diminished, so that it is possible by means of this drug to push digitalis therapy in a manner heretofore unknown.

121 Two Well-Known Tonsil Dissectors Mounted in Convenient Form on a Single Handle. C. M. Harris, Johnstown, Pa.

120. **A New Tongue Depressor.**—The tongue depressor devised by Layman is intended especially for operative work under a general anesthetic, when the tongue is held by an assistant. The instrument conforms readily to the shape of the floor of the mouth, when the tongue is depressed, holding the tongue firmly downward and forward. The handle is so constructed that it affords a firm, non-slipping grip. There is a groove on the inner side of the upper part of the handle, in which rests the index finger, and below the groove the handle is obliquely fluted. The handle is set at an obtuse angle from the rest of the instrument so that it is out of the way of the patient's chest. The part of the mouthpiece that joins the handle is so shaped that it overrides the teeth easily; the drop or downward curve at the end, which joins the tip, is so placed that it permits a free forward or backward placement of the instrument. One size tongue depressor serves for both adults and children. The tip is nearly triangular in shape, and is serrated on the tongue sides and curves down just enough to conform to the shape of the depressed tongue. The downward drop of the tip gives an advantage of at least an inch or more over the ordinary right-angled tongue depressor; thus the tongue is held in the desired position with less effort. It does not obstruct the view of the operative field, and is out of the way of other instruments.

134. **Determination of Gas-Forming Bacteria.**—For those observers who desire to determine the presence of all gas-formers, including *B. coli*, to the highest accuracy, the use of liver broth is recommended by Jackson and Muer. In the examination of water, dilutions of 0.1, 1.0 and 10 c.c. of the sample may be inoculated into lactose bile and another series into liver broth. Positive tests in the lactose bile indicate the degree of recent pollution with the colon group. Gas formation in the liver broth indicates the degree of contamination with gas-forming bacteria, both attenuated and vigorous. Any difference in the results obtained in lactose bile compared with those found by transplanting within twelve hours from the liver broth into a second set of lactose bile tubes gives a fairly accurate idea of the amount of attenuated *B. coli* present. Negative results in both sets of bile tubes and positive results in the liver broth usually show that the gas-producing bacteria present are not of the colon group.

136. **Blood in Pneumonia and Scarlet Fever.**—The observations recorded by Tunnicliff indicate that, as a rule, there is an increase in the phagocytic power in the leukocytes in mild cases of pneumonia. In mild and uncomplicated cases of scarlet fever, there is no change in the phagocytic activity of the leukocytes. In severe cases of pneumonia and scarlet fever, the phagocytic power of the leukocytes is generally diminished during the height of the disease, but when the patient improves, it rises above normal, to which it returns during convalescence. Although the opsonic power of the serum is specific, there is no such specificity in the phagocytic power of the leukocytes, so far as Tunnicliff's results indicate. So far as pneumonia and scarlet fever are concerned, variation in the opsonic power of the serum and in the phagocytic activity of the leukocytes, as a rule, is accompanied by a corresponding variation in the pneumococcidal or streptococcidal power of the serum and the leukocytes.

138. **Transmission of Spotted Fever.**—From Mayer's experiments it appears that in so far as ability of ticks from various regions to transmit the virus of spotted fever is concerned, the disease might find favorable conditions for its existence in localities other than those to which it now is limited.

140. **Time Relationship of Wood-Tick in Spotted Fever.**—The minimum duration of feeding necessary for a tick to infect a guinea-pig, Moore found to be one hour and forty-five minutes. The average time necessary seems to be about ten hours, while twenty hours were almost constantly infective. The duration of feeding necessary to infect a tick is approximately twenty-five hours, while the minimum incubation period in the tick was not definitely determined. With ticks obtained

from Nature it is necessary to infect the tick, and the incubation period in the tick will be found to be much less than is indicated here.

143. **Primary Vaccinations.**—*This is a strong endorsement of vaccination, which Amesse says is the safest, simplest and most potent specific prophylactic in the field of preventive medicine.* Of itself, it is essentially harmless; the infections sometimes complicating the operation are due to faulty technic on the part of the physician or unclean handling on the part of the patient. The plain duty of the profession, therefore, is to advocate, in season and out of season, early vaccination, preferably during the first years of life, and again at the age of 12. *Compulsory health laws of this character,* while apparently antiquated and oppressive, must continue to be *enforced* so long as public sentiment, in purely medical affairs, questions or denies the deductions of large experience and ripe judgment.

153. **Falling of the Humerus.**—*In 1879, Jonathan Hutchinson* reported a case under the title of "An Incomprehensible Case of Arm Paralysis with Recurring Dislocation of the Shoulder." Thomas has seen three cases of what he believes to be essentially the same condition. He attempts to show that it is only a variation of the ordinary anterior dislocation of the shoulder, and that paralysis is the result of the displacement in the joint, not of actual nerve rupture, although the latter condition may occasionally be present. He believes that the *importance of the lesion of a dislocation of the shoulder and its analogous condition, a sprain, has not been appreciated in the* etiology of obscure brachial paralyses. For the sake of brevity, Thomas proposes the name "dropped shoulder" or "dropped humerus" *for this condition, because* according to his experience it is the distinguishing feature and the primary and underlying cause of the whole trouble. He believes that it is the result of the tearing away from the humerus of the attachments of the upper part of the capsule with or without those of the external rotators from the greater tuberosity which is in the upper part of the joint. All three of his cases were apparently the result of an anterior dislocation, which was associated with a downward displacement of the humerus, but had not the usual rigidity of a dislocation. By operation in such cases, the normal joint relation can be restored, and the operation can be followed by a complete or almost complete return of function in the paralyzed muscles. Such a result was obtained in two cases, the operation being performed in one case eight weeks and in the other five weeks after the accident which caused the trouble. How long after this accident the result can be obtained remains to be determined. *There is* some reason to hope that the paralytic dislocation of the *shoulder* ascribed to poliomyelitis and to injuries of the brachial plexus at birth may be due to a similar cause, and that by early operation a cure may be obtained.

1. **Acute Emergencies of Abdominal Disease.**—The catastrophes which occur within the abdomen are not, Moynihan says, strictly speaking, "acute;" they are, on the contrary, usually the result of the abrupt transition from a quiescent to an acute phase in a disorder of long standing. An acute emergency can, therefore, be prevented by a timely recognition *of the value and the significance of the early symptoms,* so often ignored or misunderstood, of the chronic malady in which it is the final development. The sudden occurrence of an attack of intolerable agony in the abdomen, associated with tense rigidity of all the abdominal muscles, indicates that there is an acute lesion which needs immediate surgical attention. These two signs, and these alone, are an urgent warrant and compulsion to treat the case at once by operation. *A differential diagnosis is generally possible if strict* attention be paid to the details of the history, and if the firm abdominal wall be searched for a tender area of supreme resistance. Shock is not a symptom of perforation, for in the early hours after this disaster has occurred the pulse is very little altered in volume or in rate. In all cases *of abdominal pain,* especially in children, Moynihan says that the use of aperients should be avoided.

2. **Chemical Composition of Renal Calculi.**—Experimentation has convinced Moore that the formation of renal calculi has

for its basis a condition of diminished oxidation, in which there appear primarily calcium salts of incompletely oxidized bodies, such as calcium oxalate and calcium urate, associated with calcium phosphate. Further, such diminished oxidation, occurring locally or generally, is seen in many pathologic conditions, such as calcium salt deposition in bone in old age, in tuberculous lesions, in gout, in arteriosclerosis and generally in calcification processes in the body. The tendency toward such deposition increases with age, and is probably accompanied by an increased alkalinity of the body fluids.

3. **Renography.**—This is a report on a study of the abnormal movements of the living kidney, and a hint of its bearing and influence on renal surgery. Fenwick utilizes skiagrams of the kidney region made during forced inspiration, then forced expiration, and finally a combination of both with posture. The results are most striking, not only as bearing on the detection and study of the over-movable kidney, or in aiding in the detection and elucidation of false shadows, but in indicating the technic of operative procedure. The method is described in detail. Some of his findings he summarizes as follows:

> If I come across a fixed dense kidney, with profuse hematuria, I know I have to deal with a carcinoma of the kidney that has passed through its capsule, and has fixed it so that there is no use operating; that I shall not be able to get the kidney away without damaging the inferior vena cava or abdominal aorta, or without getting a rapid recurrence by opening up planes along which the malignant growth has interpenetrated.
>
> A fixed dense kidney shadow high up under the costal arch, with profuse, intermittent hematuria, means a "too-late" cancer, for it denotes a malignant kidney that has become glued, and is therefore inoperable.
>
> A fixed shadow of a dense kidney, with stinking pyuria and shadow of pelvic stones, means nephrectomy, and, if the surgeon is wise, subcapsular nephrectomy by the lumbar incision, without touching or separating more of the pericapsular attachments than is just necessary to enucleate the organ and control its pedicle. The surgeon who acts thus will not lose these severe cases.
>
> A fixed dense kidney shadow without stone but with *B. coli* pyuria or staphylococcus pyuria generally needs the simplest pelvic drainage through the loin without disturbance of the pericapsular area.
>
> A dense fixed kidney shadow with pyuria needs serum treatment for the corticitis.

6. **Therapeutics of Sugar.**—Sawyer has used cane sugar freely and frequently during the last ten years or so with success in a variety of morbid conditions. In wasting disorders, in various forms of anemia, in adynamic varieties of rheumatism, and especially in the neurasthenic manifestations of neurotic persons, he has found the continued ingestion of cane sugar markedly beneficial, increasing weight and power, appearing to act not merely as a nutrient but also as a tonic in the best senses of that word, gently stimulating the vital energies to an aroused action by a kind of mild stimulation, slowly produced and permanent in effect. For an adult, he has usually prescribed from ¼ to ½ pound of lump cane sugar, to be eaten slowly daily, a lump or two to be taken at odd times through the day or night, but not just before a meal, the patient always carrying a little store with him, and eating some of it when so disposed.

8. **Heart Failure.**—In this, the first paper in a series, Mackenzie considers particularly the inadequacy of the back-pressure theory to explain heart failure. He says that the theory of heart failure from back pressure lays stress on and magnifies the factors of little importance and ignores the essential factors in the production of heart failure. The back-pressure theory leaves out of consideration the fact that the valve lesion may be a steadily progressive one, and it omits the still more important fact that there are coincident changes going on in the structure of the heart muscle, impairing its efficiency, and leading up to the essential cause of heart failure. But most important of all, this back pressure theory has failed to recognize that the changes which have led directly to the production of heart failure and produced such symptoms as dyspnea, ascites, enlargement of the liver, are due to the sudden inception of a different rhythm in the heart's contraction by fibrillation of the auricle. He attempts to show that the accepted view of heart failure has been based on a misconception of the means by which it has been brought about and that certain phenomena associated with heart failure had attributed to them, in consequence of this association, a significance which they do not possess.

20 *An Unusual Case of Gunshot Wound of the Skull. W. L. Harnett.
21 *The Eye of Surgical Needles: A New Form. J. L. Thomas.

15. Also published in *British Medical Journal*, April 1, 1911.

16. **Total Enucleation of Prostate.**—In connection with these 200 operations cited by Freyer, there were nine deaths, or 4.5 per cent., the causes of death being as follows: 1. Five patients died from uremia: in two, aged 59 and 71 respectively, necropsy revealed extensive pyelonephritis; in two, aged 76 and 83, necropsy showed long-standing backward pressure changes (aseptic) leading to almost complete absence of secreting tissue in the kidneys, only a thin layer of cortex remaining; and in one, aged 73, the patient was suffering from an extreme form of paralysis agitans. 2. Two patients died from exhaustion. In one of these, in whom death occurred thirteen days after the operation, there were almost daily rigors with high temperature, though the bladder was clean; no doubt the kidneys were pyelonephritic, though no necropsy was obtained. The other, aged 87, had been confined to bed for six weeks from pneumonia immediately previous to operation. 3. One patient, aged 74, very stout, suffering from severe cystitis, chronic asthma and bronchial catarrh with dilated heart, succumbed from bronchitis twenty-two days after operation. Spinal anesthesia was tried in this case but failed, and general anesthesia had to be employed, which, no doubt, was responsible for the fatal bronchitis. 4. In a man, aged 78, double vasectomy and subsequently castration had been performed by another surgeon several years before, without any benefit to the prostatic symptoms. For two years before coming under Freyer's care he had passed urine through a suprapubic fistula established for this purpose. The apparatus fitted badly, owing to the bladder being filled by the enormous prostate, causing great pain and frequent hemorrhage, and urine constantly leaked beside the tube. Altogether the patient was in an extremely wretched condition, and begged to be relieved at any risk. The prostate, which weighed 11 ounces, was easily enucleated, but the patient succumbed to shock in eight days. Freyer calls attention to the fact that in all of these nine cases in which death supervened on the operation the patient was afflicted with one or more grave complications which must have proved fatal after much suffering. In no case did death ensue where the vital organs were sound at the time of the operation. Had the cases been selected, therefore, the mortality would have been *nil*.

17. **Pulmonary Tuberculosis and Bovine Tuberculin.**—After a large experience in the treatment of tuberculosis in all its forms, Raw has come to the firm conclusion that tuberculin is a valuable remedy in a great many cases. The special variety of tuberculin to be used must be determined by the nature of the infection, and as nearly all cases of pulmonary tuberculosis or "consumption" are of human origin—that is, they are caused by the bacilli of the human type—it is necessary to use a tuberculin prepared from the bacilli of the bovine type, and named bovine tuberculin. In fact, he declares, one must *inject* the opposite kind of tuberculin. Bovine tuberculin is less irritating and less liable to produce reaction when given in the larger doses in cases of consumption. Raw does not consider tuberculin a specific remedy in severe tuberculous infections; but combined with other methods of treatment, directed to raise the general nutrition, assists in producing immunity of a more or less temporary character, but its chief effect seems to be to prevent the further spread of the disease, and to inhibit the growth of the bacilli in the human tissues, so that as the original tuberculous process dies out no further development takes place. In other words, it has a specific action on the blood in retarding the growth of tubercle bacilli. The immunity which it produces must be arrived at slowly and with caution, so that the blood may be

very gradually accustomed to its presence, and it cannot be too strongly emphasized that all tuberculous infections of however mild a type become constitutional or blood infections in a very short time, as is evidenced by the skin reaction of v. Pirquet.

20. **Bullet Wound of the Skull.**—In the case reported by Harnett, a spent bullet penetrated the skull through the squamous portion of the temporal bone; passed between skull and dura without injuring the latter and lodged in the pars petrosa.

21. **Eye of Surgical Needles.**—The eye of the needle used by Thomas has a side entrance protected by a spring grip—like a harness snap.

March

24 *Sixteen Cases of Hebosteotomy from the Clinics of Berlin, Munich and Königsberg (Pr.). E. B. M. Haarbleicher.

24. **Hebosteotomy.**—Haarbleicher lays emphasis on the fact that to avoid disastrous risks hebosteotomy must be performed with a very exact technic, relatively early in labor, and in carefully selected cases, uncomplicated by any previous obstetric interference. He also states that the benefit to be expected in a subsequent delivery is, to say the least, problematical. Even after a strikingly successful operation and uneventful immediate recovery, the condition of the patient is not always enviable, especially in the case of a working woman who is compelled to return to her duties after a short convalescence. Thrombosis, prolapse, sacral pain, drag on evidently although the gait is relatively seldom disturbed. Statistics show that 80 per cent. of deliveries with contracted pelves are spontaneous, if left to Nature, but if hebosteotomy is not performed till the child is in danger, or till both mother and child have suffered by a protracted labor, the goal of the operation, a living child, is uncertain, and the mother incurs a grave risk.

In order to ensure a living child at minimum risk to the mother, hebosteotomy must be performed early in labor, and as no certain benefit can be claimed for future deliveries, it has no advantage over Cesarean section. Although the technic of the operation, as now developed, is brilliantly simple and exact, Cesarean section in equally skilled hands has never shown such a list of disasters. Cesarean section overcomes all mechanical difficulties, whereas in all pelvic enlargements these have still to be faced. The exact relation of the size of the head to that of the pelvis, the condition of the child, and resistance of the soft parts cannot be gaged with certainty. Injury to the bladder and soft parts, if avoided by the technic of the operation, may occur when the bones are pressed apart by the passage of the child's head and especially so if the delivery has to be aided by forceps or version. To avoid these disasters the patients must be selected so carefully that the field for hebosteotomy must remain a narrow one, viz.: multiparæ, with a conjugata of not less than from 7 to 7.5 cm. in a flat, or 8 cm. in a generally contracted pelvis, when a segment of the head has already entered the pelvis, and it is quite clear that only a very little increase in the pelvic measurement is required for the head to slip through easily, when the child has not been endangered by previous attempts at delivery, e. g., version, forceps or induction of premature labor, and when the mother is not infected. Even in these cases Cesarean section will be considered by many to hold the field.

31 The Protein Requirements of the Body. E. P. Cathcart.

30. **Treatment of Sciatica by Saline Injections.**—Of twelve patients treated by saline injections by Hay, eight were cured, one was made worse and three were lost sight of. With regard to the technic of the injection, Hay injects at the sciatic foramen or at the gluteal fold, according as pressure causes greater pain at the one point or the other. To find the foramen he draws imaginary straight lines from the posterior superior iliac spine to the tip of the great trochanter and to the middle of the ischial tuberosity, bisects the angle contained by these lines, and measures 2½ inches along the bisecting line. At the gluteal fold the nerve lies midway between the trochanter and the tuberosity. To ascertain whether the needle has penetrated into the nerve, press the plunger of the syringe gently so as to expel a few drops of the solution. If the needle is in the nerve the patient experiences a sensation as if something were trickling down within the leg to a variable distance, sometimes only to the middle of the thigh, sometimes as far as the heel. In evidence of the permanence of the cure, Hay cites the case of a man whom he injected eleven years ago. For several years before the man was treated, he was confined to the house with sciatica every winter for periods varying from a few days to many weeks; since being treated he has never lost a day's work.

39. **Roentgen-Ray Penetrometer.**—Hernaman-Johnson's procedure is based on the determination of a point at which a screen first became faintly illuminated. The essential part of his apparatus is a slide made in two pieces, numbered from 1 to 6 and from 7 to 12, and consists of squares of metal arranged according to thickness in geometrical progression. The rays from the focus tube on their way to the screen have to pass through this slide. As soon as a faint fluorescence becomes visible, it is the penetration number of the tube. Hernaman-Johnson has graded his instrument against a Wehnelt radiometer, so that the numbers correspond approximately to this scale.

45 *Diagnostic Importance of the Concentration of Urine. Significance of Polyuria. (Volume des urines et concentration maxima.) J. Heitz-Boyer and Moreno.

41-43. **The Professional Responsibility of Physicians and Surgeons.**—This issue of the *Presse Médicale* is devoted to articles bearing on this subject written by lawyers and physicians, with a discussion at a joint meeting of members of these professions.

43. Permission to Operate on Minors.—The French law gives the parents and guardians the right to forbid operations on minors and the insane, and Picqué cites examples to show the evils resulting from this law, as for instance when the father of a girl between 20 and 21 refused to permit the amputation of her leg on account of a sarcoma of the lower end of the femur, declaring that he preferred death to amputation for his daughter, notwithstanding the girl's agonized appeals for the operation. He also cites instances in which the family refused to permit a needed operation on an insane member of the family, their refusal often being dictated by sordid or criminal motives. Picqué describes his efforts to influence legislation to correct such deplorable conditions, but he has been unable to accomplish anything to date in this line.

45. Diagnostic Importance of Maximal Concentration of Urine.—Heitz-Boyer and Moreno distinguish between a facultative polyuria in which the increased amount of urine depends on conditions external to the kidney, such as the amount of liquid ingested, influence of diuretics, etc., and a true or obligatory form in which the kidney is unable to excrete the solids of the urine in greater concentration. In true polyuria a distinction must further be made between the total amount of solid substances eliminated and the concentration of the urine in these substances. The total amount of solids depends on the diet and is no criterion for appreciation of kidney functioning. The important factor, therefore, in the modification of diuresis is the maximal capacity for the concentration. This depends on the state of the kidney parenchyma, and it is thus an index of its permeability. The maximal concentration of urea, for instance, is a direct and reliable index of one of the principal functions of the kidney. For each individual there is a certain figure above which the kidney parenchyma is unable to eliminate the different substances of the urine; this figure is the maximal concentration for the substance in question. To make the test, the individual limits as much as possible the intake of fluids while ingesting as much as possible of the substance in question. In this way the kidney is forced to eliminate the maximum of the substance in the minimum of water, that is, in the most concentrated form. A healthy man given increasing amounts of urea eliminated from 40 up to 120 gm. of urea a day, but the urine never contained more than 4.5 per cent. of urea. This was his maximal concentration. In a case of nephritis, the patient taking 20 gm. of urea for four days and then 40 gm. for a day and then none, the maximal concentration ranged from 1.45 to 2.05 per cent. in the seven days of the test. The body has reserves of water to draw on, so that the concentration of the urine is regulated by physiologic laws. Much more water is ingested ordinarily than is actually needed for urine production, so that there is enough, even when the intake is much restricted below the ordinary, for production of urine. Instead of basing our diagnosis on the volume of urine in the twenty-four hours, which is such a variable and unreliable index, depending on so many casual factors, the authors declare that the diagnosis should be based on the maximal concentration which is an exact and scientific index of the actual functional capacity of the kidney in respect to solid substances. It is easier to estimate the maximal concentration of urea than that of salt, so that urea is generally used for the test.

46 *Headache from Nodules in the Muscles. (La céphalée musculaire.) F. Rose.

April 5, No. 14, pp. 157-168

47 Standards for Registration of the Venous Pulse. (De la notation et de la lecture des tracés du pouls veineux.) L. Bard.

46. Muscular Headache.—Rose refers by this term to the pain caused by nodules forming in the muscles of the head and back of the neck. It is sometimes called chronic rheumatic headache or nodular and callous muscular cephalalgia. The lumps in the muscles can be palpated with the lubricated fingers. They may be in the subcutis or muscles and may range in size from minute points to actual lumps, and are extremely painful even under slight pressure, especially those in the top of the scalp. They pass through three stages, swelling, elastic resistance and cartilaginous induration, and the tonicity of the muscle is always exaggerated, sometimes to actual contracture. The points where the muscles are most painful are near the articulation of the sternum and clavicle and the upper cervical vertebræ, especially the fourth, and the articulation between the atlas and the spine. Light pressure at these points causes the muscles to contract, while strong pressure abolishes the pain and relaxes the muscles. This muscular headache has been studied mostly by Swedish writers. The rare acute cases subside under salicylic or sedative medication; even in the chronic cases the prognosis is also good under suitable massage treatment. Each of the hypertonic muscles should be examined individually. With scientific massage it is possible to relieve the patient speedily after the affection has been once diagnosed. Müller states that of 140 patients in this category who were given over twelve massage treatments, 119 were cured, while 21 were either not benefited or the ultimate outcome is unknown. The trouble is most frequent in women, but it has been encountered in children. There is usually a history of some toxi-infection, influenza, recurring sore throat, acute and chronic muscular or articular rheumatism. Some explain the nodules as gouty deposits; the *Muskelschwielen* may involve the nerves in the nodules. A rheumatic origin seems probable, but Müller noticed a tendency to goiter in a number of the patients. It is possible that the contraction of the muscles in the front of the neck may compress the thyroid and thus induce insufficiency and set up a vicious circle. This assumption throws light on the headache and facial and cranial neuralgias sometimes observed with defective functioning of the thyroid. Müller asserts that headache which cannot be traced to an organic affection of the brain, skull, eyes, nose or ear is sure to be of this muscular cephalalgic type. Even with alcoholism, the headache may be of this type and may be cured by massage, as also when it is a complication of neurasthenia.

48. Obstruction of the Intestine During or After Appendicitis.—Ruge reviews forty-four cases of this kind, including fourteen in which the ileus was due to atony of the bowel, ten with broad adhesions and eighteen with narrow, one with an inflammatory tumor and one with stenosis from ulceration in the cecum. These appendicitic cases formed 17.9 per cent. of the cases of ileus in his experience in the last twenty years, but only 1.8 per cent. of the total cases of appendicitis. The diagnosis is frequently difficult as the appendicitis may mask the ileus or there may be no known history of appendicitis or merely a vague history. In twenty-one cases nothing was known of any history of appendicitis or else it had been extremely mild. In twenty cases the ileus accompanied the appendicitis. Violent peristalsis is the best sign of obstruction, and when the obstruction is suspected a history of appendicitis existing or in the past should suggest the necessity for an immediate operation. The obstruction is generally high up and operative treatment must be more extensive than with simple mechanical ileus, on account of the danger from the appendicitis. Only ten patients recovered in the twenty with existing appendicitis and only thirteen in the twenty-four with trouble due to the relics of appendicitis. In the entire number there is no case in which an early operation was done for the appendicitis: this confirms the importance of an early operation to ward off such contingencies in the future.

50. **Sarcoma of the Calcaneum.**—Stern has encountered two cases; the patients were men of 54 and 28 and the growth was inoperable in the first case. In the other the trouble had been supposed to be of an inflammatory nature and a plaster cast was applied four weeks after the first symptoms. The increase in the pains compelled its removal in ten days when the ankle was found more swollen than at first and the patient refused to permit massage. The progress of the growth soon required amputation of the leg and the man died of metastasis in a few months. In the other eighteen cases on record, the sarcoma was mistaken for a tuberculous process in a number, but the difference in the shape of the joint might have excluded this. With tuberculosis, the joint assumes the spindle shape while this is not generally observed with sarcoma until the soft parts become involved, although in one of Stern's cases the spindle shape was pronounced from the first. The knobby tuberculous process is usually in the capsule, while with sarcoma it is more liable to be in or near the cartilage. So long as the sarcoma is restricted to the bone, the joint swelling shows a tendency to subside in most cases, but Stern's case was an exception to this rule likewise. With sarcoma, the skin is not reddened as with inflammation, and the movements of the joint are less painful, until the growth involves the joint surfaces. This does not occur for a comparatively long time as the cartilage seems to display great resistance to the spread of the sarcoma in most cases, although not in all. The pain with sarcoma is described as a pulling or tearing or neuralgic pain, while with inflammation it is more a throbbing. Fever, chills and local pains may come on suddenly as the first symptoms of the sarcoma. In some cases the pains and disturbances may be ascribed to flat-foot; this occurred in Borchardt's case, in which the patient was treated for nine years on this assumption and all kinds of insoles, massage, etc., having been applied. Radiography is extremely useful in differentiation of the sarcoma, the uniform light patch being different from the picture in tuberculosis and osteomyelitis with which there are generally shadows scattered through the light patch. The thickening and disintegration of the periosteum help in differentiating gumma from sarcoma, which otherwise the findings resemble. There is no time to waste, Stern says, in tentative antisyphilitic medication. Radioscopy is further useful with sarcoma as it permits discovery of metastases in the lungs or elsewhere before they make their presence felt, and it reveals the first tendency to recurrence after removal of the growth. With exploratory puncture or excision, the scrap should be taken from the periphery of the growth as the conditions differ materially at this point with gumma and sarcoma while in the center it is hard to distinguish between them. Before operating, the glands should be investigated; if they show signs of metastasis, there are probably metastases at other points. Of the twenty sarcoma patients two were known to be alive two years after removal of the spindle-cell and giant-cell sarcomas and one five years after removal of a sarcomatous chondroma. In Stern's two cases the growth was a small, round-celled sarcoma with occasional giant cells. The small, round-celled sarcomas seem most rapidly fatal. It is important after the amputation to saw the bone across to ascertain how far the sarcoma has proliferated up into the bone marrow; exarticulation of the knee or hip may be the preferable technic.

53. **End-Results of Operations for Benign Gastric Disease.**—Galpern has reexamined 128 of 160 patients of this class, and he here classifies them and the ultimate outcome, comparing this material with that reported from other clinics. The best results were obtained with cicatricial stenosis of the pylorus; next to this, in the cases of pyloric ulcers, while the poorest results were found with ulcers at other points in the stomach. In twenty-eight cases there was recurrence of symptoms or peptic duodenal ulcer developed.

54. **Primary Resection of the Large Intestine.**—Haberer reports nineteen cases of primary resection of the large intestine at von Eiselsberg's clinic at Vienna. Three of the patients did not survive the operation; one of this group had had a febrile sore throat a short time before and the fatal peritonitis was due exclusively to streptococci. He regrets that the operation was not postponed to allow time for the streptococcus infection to die out. In another similar case, although the patient recovered, yet streptococcus peritonitis followed the angina and streptococci could be cultivated from the blood. In the third case the patient was doing well up to the fifth day after extensive resection of stomach and intestine but then a suture on the ascending colon gave way. In all the other cases the wound healed by primary intention. Eiselsberg makes it a principle to use the simplest technic and ordinary instruments in all his surgical work, for the impression and effect on the students who, when they come to practice, will seldom have more than the most modest equipment.

56. **Poisonous Action of Metallic Lead in the Body.**—Lewin records a large number of interesting cases of lead poisoning from swallowed shot or the practice of holding shot in the mouth, or inhalation of air laden with lead particles, bullets shot into the tissues, etc., discussing the chemical action of the organic fluids on the lead. His conclusions are in favor of the necessity of extracting without delay the metal body which is liable to act sooner or later in an insidiously harmful way on the vital functions. He has been growing more pessimistic in this respect with increasing experience. No one can tell, he says, how soon the metal will become mobilized under chemical action, and when this has once happened it is practically impossible to control the consequences. The argument that people are known who have carried bullets about in them for years without harm is not based on scientific evidence, he declares. There are no records of any such persons followed carefully through years, and no records as to the symptoms with which death finally came to them. It is not known whether they died finally of lead poisoning or not. Internal medication, with potassium iodid for example, is inadequate to cope with the constant fresh supply of lead being fed into the blood from the mass in the bullet or shot. In one of his cases the symptoms of lead poisoning were observed from merely a single shot which had lodged between the teeth as the woman was eating an apple.

58. **Intermittent Limping and Spinal Symptoms After Poisoning with Male Fern.**—In the case reported by Magnus-Levy the patient, a man of 38, took 8 gm. of extract of male fern with 16 gm. of castor oil, the combination being a proprietary mixture (Tritol-Stark) to expel tapeworm, the man believing that he had this parasite and taking the medicine without consulting a physician. For several years he had had symptoms suggesting a slight tendency to intermittent limping, but not sufficient to impair his usefulness as a policeman. The trouble was most pronounced in the morning, after the night's rest, the same as in a case recently reported by H. Curschmann. The male fern caused vomiting, violent clonic and tonic cramps, irritation of the kidney and fever, but the eyes did not seem to be affected. The tendency to circulatory disturbances was seriously aggravated, the toes were congested, numb and with blue patches on the leg. The man had to stay in bed for six weeks with varying pains in the contracted leg, and he was left with serious paresis of the leg, the type suggesting poliomyelitic paralysis. Levy is inclined to explain the syndrome as the result of a direct toxic action of the drug on the already diseased artery wall, on the cells in the spinal cord, and also on the smooth musculature. The artery cramps seemed to affect predominantly the vasa vasorum of the already pathologic blood-vessels of the left leg and of the lowest segment of the spinal cord, where the toxic action of the drug was felt most powerfully and inflicted permanent injury. The patient improved under iodin and electricity so that after a four-weeks' course he could walk for ten or fifteen minutes without being obliged to stop and without fatigue. The skin is more of a normal tint and the pulse in the arteries of the foot is occasionally perceptible although weak. The effect of iodin is soon apparent in these cases, the parts showing the influence of better nourishment and function. The benefit from iodin in intermittent limping is accepted by Levy as sustaining its efficacy in general arteriosclerosis although ordinary arteriosclerosis is by no means necessarily the causal factor in intermittent claudication, and the latter may improve even without the use of iodin.

59. **Disease of Cardiovascular System.**—Honigmann states that more than 20 per cent. of the mortality after the age of 40 is due to cardiovascular disease, and that the proportion of persons with these disturbances is still higher among the well-to-do. The general practitioner should aim to make a correct prognosis rather than to seek for the exact anatomic basis. Even if the newer methods of estimating the functional capacity of the heart are able to do all that is claimed for them, yet it would be impossible, he says, to get the ordinary patient to submit to the full battery of these tests. And even if he would, the tests reveal only isolated phases of the cardiovascular functioning; even the determination of the blood-pressure is dependent on so many factors that it is impossible to interpret it always exactly, and the gross variations can be estimated with the finger as well as with the most complicated apparatus, unless a prolonged study of the pulse is made which is not practicable outside of institutions. In reviewing his twenty-five years' experience with patients with cardiovascular disturbances under observation for many years, Honigmann has been impressed with the comparative frequency of three types: fibrous degeneration of the heart muscle, angina pectoris and renal arteriosclerosis with heart trouble. The main feature of the first type, the chronic myocarditis, is the severity of the disturbances from lack of compensation while the prognosis is more favorable than in other forms of heart disease. These patients suffer from shortness of breath with physical or even mental effort; the pulse is irregular and it may remain so after compensation has been restored and the pulse is full and strong. The irregularity is the result of some fibrous patch in the heart and is a favorable sign in these conditions. The disturbances in these cases come on gradually, but the second type is distinguished by the sudden onset, and after subsidence of the attack of cardial asthma all returns apparently to normal. The more the dyspnea symptoms in this type predominate, the better the prognosis, while sensory disturbances, suggesting angina pectoris, render the prognosis graver. If the patient can spare himself in the intervals, this form of heart disease may permit long survival. In a case cited, eight years elapsed after the first attack before the patient succumbed, and the trouble had probably been developing long before that first attack of cardial asthma. It is typical of the disturbances in this group of cases that they do not follow the overexertion at once but come on several hours afterward. Signs of general arteriosclerosis are evident as a rule in these patients, but the heart is not dilated although symptoms during the attack may indicate that it is. Development of a Cheyne-Stokes type of breathing and psychic symptoms naturally render the prognosis graver. When the attacks commence in the form of angina pectoris, the heart is close to the limits of its functional capacity and in his experience such patients have survived only for six or nine months.

In the third type, the arteriosclerosis involves principally the kidneys although the kidney symptoms seem to be merely a by-phenomenon. The albuminuria and tube-casts in the urine vary from time to time and a careful watch should be kept over them and over the hypertrophy of the heart. When the left heart is hypertrophied and the disturbances are thus perfectly compensated, the prognosis is not bad. With slight changes in the mode of life such patients can continue at business even if annoyed by sensations of pulsation, especially before dropping to sleep, frequent fatigue and a peculiar oppression in the chest. The functional capacity of the heart must be estimated from the behavior of the pulse and other organs. Cheyne-Stokes breathing and the psychic behavior of the patient are instructive signs with cardiovascular disease, especially slight confusion on waking from sleep, carrying dream impressions into the waking state. Occasionally these patients forget names and words, they feel depressed and irritable without cause. Especially after the attacks a kind of confusion persists, although physically the patient feels comparatively well. He is liable to confuse places and imagine he is in some place where he used to live or is in some foreign land; and he confuses periods of time. These phenomena may last for a few days or only hours, but they have a bad prognostic significance; when they have subsided the patient is liable to brood over them and finally they become more constant. In time they may change to agitation and excitement, with distrust of the family and friends. In cases in which these psychic disturbances were observed, the patient never survived for longer than a year or year and a half in his experience. These symptoms were never encountered with the chronic myocarditis or coronary angina but they were frequent with general arteriosclerosis and most so with arteriosclerotic contracted kidney. They coincide with the increase in the insufficiency of the cardiovascular apparatus, and thus seem to form an integral part of the disturbance, and hence are important for the prognosis. Honigmann warns against premature and injudicious use of digitalis; bed rest alone will often answer the purpose. Morphin on the other hand is often indispensable. It is not wise, he thinks, to inform the patients that they are dangerously ill. So long as the state of compensation permits, the trouble should be painted for the patient in brighter colors than as the physician sees it. Particularly with cardiovascular disease should every effort be made to refrain from depressing the patient, who knows that something is wrong with his heart and that he must spare it extra exertion, but his business need not be interfered with; the danger lies in the hours outside of business, in sports, eating and drinking. In proscribing dangerous factors the physician must constantly weigh whether the good to be derived from his restrictions will counterbalance the depression caused by the loss of coffee, alcohol or exercise, etc. By permitting the minor pleasures of life it may be possible to secure more important changes in the entire mode of life.

60. **Functional Ileus in Infants.**—Blochmann reports three cases of suddenly developing occlusion of the bowel in young infants which he was able to remedy by introducing a rubber tube into the anus and pushing it up into the bowel for a little over 3 inches. This evidently opened a valve-like

contraction or fold in the bowel; flatus and stools came at once and the children were cured. One succumbed to the sepsis resulting from the long continued ileus before treatment was applied. The others recovered although one had recurrence of the trouble a few months later, conquered anew by the tube at the first sign of trouble. In all the children the abdomen was enormously distended which is never observed under other conditions in breast-fed infants with obstruction of the intestines even for so long as five days. This valve occlusion of the intestines may produce conditions similar to those in Hirschsprung's disease and may aggravate this disease if it be already present.

64. **Scarification in Place of Decapsulation of the Kidney.**—Zondek reports experimental research and clinical experience which show that decapsulation is liable to entail serious injury of the kidney while approximately the same results can be obtained by merely scarifying the capsule. The surgeon's task is extremely simple; the main point is to determine the indications for operating, and this general practitioners, clinicians and anatomists must study in concert. The scarification technic spares the larger vessels better than nephrotomy.

66 and 67. These and other communications on radium were summarized in the *Berlin Letter in* THE JOURNAL, *April 15*.

73. **Quantitative Test for Uric Acid.**—Aufrecht evaporates the urine, blood or other fluid; adds a saturated solution of ammonium chlorid, separates the ammonium urate by centrifuging and titrates with potassium permanganate. The technic is described in detail and stated to be simple and reliable. The findings were regularly the same as those with the Ludwig-Salkowski test applied to control specimens.

82 Suggestions for Improved Treatment of Neuropathic and Psychopathic Individuals. H. Oppenheim.

75. **Serotherapy of Typhoid.**—Kraus and Stenitzer review the experiences with typhoid antiendotoxin in three epidemics; nearly a hundred patients were given subcutaneous or intravenous injections and when this was done early in the disease the beneficial action was unmistakable. The results confirm those reported in their previous communications on the subject and justify, they declare, further efforts in the line of serotherapy.

79. **Diagnostic Importance of Auscultation of Gastro-Intestinal Tract.**—Glücksmann comments on the neglect of this important aid for diagnosis of conditions in the gastro-intestinal tract, and describes his application of auscultation to determine conditions in regard to the motor functioning of the stomach. He does not attempt to distinguish the quantitative or qualitative features of the sounds, but merely the time of their *appearance and* their duration. He has devoted his attention mainly to auscultation of the pylorus, and has found that it is possible by this means to determine *when* and in what *manner* the stomach passes its contents along into the intestines, in short, to supervise its motor functioning. He applies the stethoscope to a *point three* fingerbreadths to the right of the umbilicus and three fingerbreadths above the plane of the latter. A long strip of paper is marked *off into* sixty numbered fields *and* at each sound that is heard the listener makes a mark on the square field corresponding to the minute as he notes it on the watch. The findings can be controlled by a rubber bulb which the patient holds in his hand that records simultaneously on a revolving drum the moment the sound is perceived. He has applied this method of examination to over a hundred persons, some healthy and others with various stomach symptoms. The stethoscope was thus applied for half an hour before breakfast. The patient then *took a test breakfast and after this* the stethoscope findings were recorded for an hour or an hour and a half. The room was kept a little warmer than usual and the findings were compared with those obtained by other methods of testing stomach functioning. Among a number of interesting facts learned by this method is that the digestive tract is never in absolute rest, the sound of fluid passing through the pylorus can be heard occasionally even with the fasting stomach, and this pyloric reflex occurred constantly at the moment when breakfast was brought into the room. The pyloric reflex occurred further much more frequently and was much more pronounced in case of disease of the small intestine. It was interesting to watch the behavior of milk; when the secretory function was at fault the milk was expelled like any other fluid from the stomach, but with normal acidity it coagulated into a solid body, as could be readily recognized by the auscultation findings; they thus revealed the existence of gastric achylia and permitted an estimation of the individual capacity for digesting milk. This may prove of great importance in pediatrics. The findings threw light also on the *action* and effects of various drugs, on the antagonism between certain drugs, morphin and belladona or drugs to correct acidity, stomach bitters, etc.

81. **Eye Disturbances After Salvarsan Treatment.**—Davids reports a case of bilateral iritis developing in previously sound *eyes two days after injection of salvarsan.* It accompanied a pronounced Herxheimer reaction, and he is convinced that all the eye affections observed after administration of salvarsan are true syphilitic phenomena, and that they might have been prevented by injecting larger doses of the salvarsan. In his case the iritis *promptly* subsided *without leaving a trace after* a second, intravenous injection of salvarsan. He reviews all the literature he can find on the subject of eye disturbances after administration of salvarsan, the data confirming, he states, the above explanation of the trouble.

95 Tumor of the Nipple. (Primäre Geschwulstbildung der *Brustwarze.*) O. Creite.

84. **Prognosis of Dislocation of Shoulder or Elbow.**—Schmidt states that the outcome was *good* in 81.5 per *cent.* of his cases of dislocation of the shoulder and was satisfactory in 69 per cent. of the cases of dislocation of the elbow, but only twenty-seven of his total material of *ninety-two* cases of dislocation of the shoulder could be traced to date, and only twenty of the forty-six cases of dislocation of the elbow. These results are much more favorable than those reported by

other German surgeons, and Schmidt ascribes the better functional outcome to the lack of orthopedic treatment after reduction. The arm is merely held in a loose sling passing around neck and wrist, and nothing more than light stroking massage is applied and this only enough to promote the circulation and hasten the absorption of the extravasated blood. The Roentgen-ray findings in the twenty cases of backward dislocation of the elbow are reproduced. The findings seem to demonstrate that the manipulations necessary to reduce the dislocation are responsible for the local ossification which interferes with normal functioning in so many of these cases. This explanation applies in particular to one of his cases in which complete ankylosis developed. The vigorous attempts to reduce the dislocation had not been successful and had evidently injured the joint so that there was a large patch of ossification in the bend of the elbow.

86. **Gasserectomy.**—Bircher states that only twelve operations for intracranial removal of the Gasserian ganglion have been done in Switzerland and he adds three more to the list. The first two patients were women 76 and 30 years old, and both were cured at once of the trigeminal neuralgia and unilateral vasomotor symptoms. The operations were done according to Krause's technic. Seven peripheral operations had been done on the first patient in the course of fourteen years with transient benefit each time after resection of a stretch of the nerve. In the younger patient all three branches of the trigeminal nerve were affected, and the symptoms indicated an intracranial trouble, so no time was wasted on peripheral operations. The assumption of an intracranial site for the trouble was sustained by the edema of the lid and the congestion in the right side of the face and right arm and exophthalmos—all of which disappeared after the gasserectomy. In both cases the external carotid artery was ligated as a preliminary measure. The younger patient for two weeks after the operation showed symptoms of mild psychic disturbance which then subsided; it is possible that the injury from the retractor holding back the brain tissue may have been responsible for this. In a third case there was so much bleeding that the operation proved exceedingly difficult. The patient was a man about 70 with pronounced arteriosclerosis which had altered the vessels so that they did not behave normally and death followed in a few hours from internal cerebral hemorrhage. Gasserectomy is evidently too long and serious an operation to be attempted with existing arteriosclerosis, especially of the vessels of the neck and head; it increases the bleeding and renders the brain more sensitive to the pressure of the retractor while it enhances the danger of apoplexy. Nearly all the fatalities on record were in patients with arteriosclerosis.

87. **Kuhn's Peroral Intubation.**—Kölle gives an illustrated description of Kuhn's flexible tube and the method of its application to aid in operations on nose, mouth and larynx, with detailed reports of three cleft-palate operations, and four of tumors in all of which the peroral intubation rendered valuable service.

89. **Acute Osteomyelitis of the Spine.**—Gundermann reports a case of this affection, the only one on record, he says, terminating in recovery. His patient was a previously healthy man of 28, and the spinal affection followed a carbuncle on the back of the neck. He was traveling at the time, and the frequent change in physicians and a complicating pleural empyema aided in retarding differentiation of the true trouble. It is the fifth case on record with complicating pleural empyema. The osteomyelitis involved the seventh dorsal vertebra, with posterior mediastinitis and irruption into the left pleura and secondary, non-suppurative involvement of the right pleura, with final irruption into a bronchus. After resection of ribs and part of the left transverse process of the seventh dorsal vertebra and evacuation of the spinal process, with removal of sequesters, and measures to control the kyphosis, the patient finally recovered. He coughed up small sequesters of bone from time to time, but by the end of eighteen months after his primary carbuncle he was in permanently good health. Staphylococci could be cultivated in pure cultures from the pleural and spinal lesions. This case and others in the literature emphasize the importance of prompt and energetic measures on suspicion of vertebral osteomyelitis. As soon as the most dangerous stage is past, steps should be taken to prevent development of kyphosis, keeping the patient in bed at first and having him wear a supporting corset when allowed to get up, which should be done very cautiously. Complete restitution is the rule. In the case reported the patient was able to resume his active duties as a cavalry officer.

90. **Incarcerated Gangrenous Hernia.**—Berkofsky analyzes sixty-one cases of gangrenous hernia and twenty of gangrene of the intestines from other cause. The mortality was 32.6 per cent. in the cases of hernia with primary resection of the bowel and 62.5 per cent. in the others. Sixteen interesting cases are reported in detail, including one with volvulus of the sigmoid flexure recurring within three years, and another with volvulus of the small intestine recurring so that the bowel twice had to be resected. When the large intestine was involved in the gangrenous process, the outcome was nearly always unfavorable, whether the bowel had been resected or not. But with gangrene of the small intestine, primary resection cured the patients.

91. **Cyst in Common Bile Duct.**—Schloessman adds another to the fifteen cases of this affection on record; in all the true cause of the trouble was not recognized during life, and the treatment instituted was directly contrary to the correct indications. His patient was a girl of 7. The symptoms in this and the other cases were merely intermittent jaundice, possibly continuing for years, a tumor in the right upper abdomen of varying size and consistency, and colic-like or continuous abdominal pains, generally proportional to the varying jaundice and tumor. The ages ranged from 4 to 24 in the cases on record, and only two of the patients were males. Exploratory puncture of the cyst in his case permitted the escape of contents into the peritoneum, with consequent fatal peritonitis. As the cyst contents were sterile, the peritonitis did not develop at once, even although the operation was not attempted until thirty hours after the cyst had been punctured. Only one case of recovery is known; the patients are usually not seen until the condition is precarious from the long cholemia, and then more precious time is wasted in trying to differentiate the trouble, so that when an operation is attempted the patients are too debilitated to recover. It is not enough to evacuate the cyst, he declares; arrangement must be made for ample communication between the bile duct and the duodenum.

93. **Treatment of Fractured Lower Jaw.**—Cuffaro fitted a strong plate over the lower teeth which held them firmly in place and immobilized the two halves of the jaw. A groove was cut out of the top of the plate, permitting the lower teeth to be used in chewing, which aided functional restitution. The results were good, with the minimum discomfort for the patient.

97. **Vital Reactions to Infections.**—Bauer discusses the various clinical manifestations of the vital reactions to infections, the so-called allergy which is evidenced in the form of immunity or anaphylaxis. The phenomena of the vital reactions are generally acute primary pictures of pathologic conditions. The changes in organs are generally the consequences of these original vital reactions. It is the task of the future, he says, to reveal the connection between them.

98. **Importance of the Steam-Jet Treatment.**—Brieger is in charge of the hydrotherapeutic institute of the university of Berlin, and he declares that the steam jet is not accorded the

importance in therapeutics which it deserves. He shows the fundamental physiologic difference between the action of dry and moist heat; dry heat has only a superficial action, as it is a poor conductor. Moist heat, on the contrary, is an unexcelled conductor and rapidly penetrates through the organs of the body. The steam jet possesses this property in the highest degree, inducing a hyperemia which may last for more than twenty-four hours. The best method of its application is the jet of steam under high pressure, which procedure he applies to a third of his patients. In sciatica he has the steam jet played on the painful points of the sciatic nerve and its main branches for ten or fifteen minutes. A combination of the steam jet with massage and passive movements is especially effectual. The steam jet softens the tissues, improving conditions for massage; dry heat leaves the tissues so dry that massage afterward is liable to be painful. The best results have been obtained with joint affections of rheumatic, gouty and gonorrheal origin, particularly when *only one joint* was affected. Excellent results have also been obtained with elbow and hip-joint disease. In one case rapid benefit was obtained by this means in a severe rheumatic affection of the jaws which had immobilized them.

99. **Differential Stain for Inflammation of the Iris and Ciliary Body.**—Fehr has confirmed in fourteen cases Hamburger's statement in regard to the remarkable way in which a stain, fluorescein, given by the mouth in a dose of 5 gm. for adults, was followed by green discoloration of the inflamed region in the eye in case of keratitis, iritis or uveitis. There is no discoloration in the sound eye or with other ocular affections, such as conjunctivitis and glaucoma. The discoloration is probably due to the increased permeability of the vessel walls.

107 *Allowing Patients to Get Up Early. (Frühaufstehen der Wöchnerinnen.) H. Pruska.
108 Ovarian Cause of Uterine Hemorrhage. (Die ovarielle Ursache uteriner Blutungen.) O. Pankow.

103. **Tuberculosis and Pregnancy.**—Schauta thinks that it is impossible to estimate beforehand whether the tuberculosis is going to flare up under the influence of the pregnancy or not, as this is liable even in the mildest cases. The records show aggravation in 75 per cent. and a fatal outcome in 50 per cent. of all cases. Even sanatorium treatment is generally unable to ward off or modify the aggravation of the disease. Allowing the pregnancy to progress to its latter half and then interrupting it, is particularly disastrous for the mother, but might be indicated in exceptional cases to obtain a living child, the mother being beyond hope. The logical conclusion from the evidence presented is, he thinks, that early abortion should be the routine procedure when a woman with certain tuberculosis of the lungs or larynx becomes pregnant. He prefers vaginal Cesarean section rather than the use of tents, which is more than liable to be followed by an ascending catarrhal affection of the tubes with suppuration. The anterior colpohysterotomy avoids this, and he supplements it by ligating the tubes, without pulling down the uterus, merely seizing the round ligament close to the uterus and ligating the tube twice, then drawing the round ligament up and suturing it over the uterine stump. It is unnecessary to bury the other stump. This technic is simple and permits restitution of the permeability of the tube if the tuberculous process should heal and the woman longs for a child. The resected tube or the ovary might possibly be implanted in the uterus wall. The other technics that have been suggested for temporary or permanent sterilization require laparotomy.

107. **Allowing Parturients to Get Up on the Fourth Day.**—Pruska concludes from the experiences at the third obstetric clinic at Prague that the morbidity of the lying-in period is materially reduced when the patients are allowed to leave the bed by the fourth day after delivery; the involution of the uterus proceeds fully as well, retroflexion is much less rarely observed, and the general health is materially influenced, he thinks, for the better. Only those are allowed to get up so early who have not required suturing, who feel well and whose pulse and temperature have been persistently normal. He compares a group of 1,000 patients allowed to get up on the fourth day with an equal number who were not allowed up till the ninth day but who might have got up on the fourth day according to the present rule. In the first group only 5.8 per cent. developed fever after the fourth day while it was observed in 10.5 per cent. of the second group.

112. **Glycyl-Tryptophan Test for Gastric Cancer.**—Neubauer and Fischer report the experiences of others with their new test which have confirmed their previous announcements that the gastric juice in normal conditions does not contain the enzyme which splits glycyl-tryptophan. The findings were positive in 84 per cent. of twenty-six cases with certain cancer, in 75 per cent. of twelve cases with clinically certain cancer, in 23 per cent. of twenty-six cases of cancer suspects and only in 12 per cent. of forty-two patients with nonmalignant stomach trouble. These figures do not include those of Weinstein as he used a slightly different technic [described with the findings in thirty-nine cases and negative findings in twenty-four other patients free from gastric cancer, in The Journal, Sept. 24, 1910, page 1085]. Neubauer and Fischer remark that absolute specificity cannot be expected in a chemical reaction like this. The data they present are compiled in this way to show the value of the test in the most objective manner.

113. **Return Cases of Diphtheria.**—Sörensen states that there were eighty-two return cases in connection with the 7,037 diphtheria cases at the Copenhagen hospital between 1889 and 1901. In only eight of the patients occasioning the return cases could diphtheria bacilli be found in the throat when they were discharged. The interval was from two to thirty-three days, the majority of cases occurring from four to twelve days *after the first patient* had returned home.

130. **The Plague.**—Albrecht was a member of the Austrian committee sent to Bombay in 1897 to study the plague. Its four members, he says, were the first to insist that rats have something to do with the plague, and they proved it by discovering the bacilli in the carcasses of rats found dead in the streets. As early as 1895 plague was known to be endemic among the marmots of northwestern Asia, and he thinks that these animals may be the perennial source of the plague. When plague first appeared in India, the pneumonic form was most prevalent but gradually the bubonic type supplanted it, and he thinks that this same experience may be repeated in China and Manchuria. With a little care, prophylaxis of the bubonic type is effectual, as he learned by his personal experience at Bombay. An encouraging feature with plague is that it spreads very slowly at first, so that there is time to stamp out imported cases before an epidemic develops. But once obtaining a foothold in a place, it seems to be almost ubiquitous, like a genius epidemicus, at least in the slums.

131. **Decapsulation of the Kidneys in Eclampsia.**—From the successful case reported and other experiences, Franz concludes that decapsulation of the kidneys may prove of great value but that there is no sense in applying this measure until after delivery. The latter alone may afford the desired relief, but if the oliguria or anuria persist or the albuminuria increases and the convulsions or coma persist, then decapsulation may prove the only life-saving measure. It was done on both kidneys in the case reported, about seven hours after delivery; the patient, a primipara of 24, was in collapse with cyanosis, tracheal râles, small pulse of 140, blood-pressure 70. The convulsions had kept up after delivery; eleven preceded and four followed the decapsulation but improvement was soon marked and progressive.

132. **Sulphur Reaction in Urine with Cancer.**—Further experience has confirmed the previous announcement of Salomon and Saxl of the presence of polypeptids, of oxyproteic acid in particular, in the urine with cancer. They have now a record of over 500 urines which have been examined for their oxyproteic-acid content. In 70 per cent. of the cancer cases the findings were constantly positive while they were positive only in a very few other cases, and those mostly very serious conditions. The reaction, however, was obtained in pregnant women the same as in cancer. Even with early small cancers the reaction proved positive in many cases. The disappearance of the reaction after the cancer has been removed testifies to its connection with the malignant disease, but it seems to be independent of the cachexia and of the size and location of the tumor. The reaction is obtained by oxidizing out the neutral sulphur element of the oxyproteic acid in the urine. This is done with hydrogen dioxid, as they describe in detail, a distinct precipitate being thrown down in the urine from cancer patients while there is scarcely a trace of precipitation in other urine.

139. **Causes of Hypertrophy of the Heart with Kidney Disease.**—Senator shows the fallacies in the various theories which ascribe the hypertrophy of the heart to mechanical, hydrostatic factors. Even injection of fluid paraffin into the renal artery, inducing embolism in the finest vessels in the kidney, is unable to produce conditions sustaining the assumption of physical factors. On the other hand, there is considerable evidence to prove that it is lack of the blood-pressure-raising substance, constantly present in sound kidneys, which is responsible for the hypertrophy of the heart with kidney disease. Either other organs work vicariously and to excess to supply this lacking physiologic substance, or some inhibiting action from some other direction is lacking. In studying the subject, a number of other organs should be taken into consideration, besides the suprarenals: this, he says, opens a broad field for research.

140. **Encephalitis and Cerebral Thrombosis.**—Laache reports a case of recurring encephalitis; the first attack ten years before had subsided under treatment but the second proved fatal at the age of 34. Except for an acute articular rheumatism in childhood the patient had been healthy. The symptoms in both attacks were intense headache, right facial paralysis and hemiplegia, with aphasia. Necropsy disclosed merely a pinkish discoloration of the white matter of the left brain, corpus callosum and cerebellum, with two foci of softening but no traces of a scar or cyst, and the vessels were comparatively intact. In another case, an acute hemorrhagic encephalitis was accompanied by secondary thrombosis of the cerebral veins. The patient was a young and previously healthy housemaid who had complained at times of severe headache during the last five or six weeks but there had been no appreciable fever. Then the headache became more severe and the girl died in five days, after three days of stupor. In a third case extensive cerebral thrombosis developed in a woman of 47, secondary to chronic renal tuberculosis and soon proved fatal. In a fourth case, an acute and intensive hemorrhagic encephalitis developed in a man of 36 with a history of epilepsy and chronic nephritis and positive Wassermann reaction. Whether syphilis or the kidney disease or both were responsible for the epilepsy and encephalitis is an open question. Eichhorst gives syphilis the first place among the infectious diseases which may entail epilepsy, but Strümpell denies that it has any connection with genuine epilepsy.

145. **Syphilis of the Aorta.**—Grau reviews twenty-three cases of disease of the aorta with a history of syphilis, three of mixed etiology and sixteen free from syphilis—his total material of aortic affections in the last two years. The latter group includes nine patients with a history of articular rheumatism. In the twenty-three syphilitic cases, there had been an interval of from six, fifteen, twenty-five and twenty-nine to forty-one years since the infection. The subjective symptoms were remarkably late in developing in the syphilitic cases while in the non-syphilitic they had been attracting attention for years. The syphilitic aortic lesions may exist unsuspected for years, without causing subjective symptoms. When these do appear, the condition is then so far advanced that breakdown of compensation follows soon after. There is less enlargement of the ventricle and less disturbances in the peripheral vessels with syphilitic disease of the aorta than with the non-syphilitic. The Wassermann reaction was positive in twenty-one of the syphilitic cases of aortic disease, but he found it negative in three certain cases. The prognosis is generally very unfavorable with syphilis of the aorta when failing compensation is observed. In three of the syphilitic cases melancholia and hypochondria were noticeable, and in another there was an actual psychosis with confusional anxiety and hallucinatory ideas; this type is apparently characteristic of the disturbances in the circulation in the brain resulting from the aortic lesions

148. **Uremia.**—The research reported confirms the importance of the presence of indican in the blood-serum as a sign of kidney disease in the stage of uremia. Recent literature on the subject is reviewed and the results of extensive clinical experience are tabulated. All the evidence shows the absence of indicanemia in health and outside of kidney disease, and its constant presence with advanced nephritis and retention of certain elements of the urine.

152 *Spiral Incision in Treatment of Varices and Leg Ulcers. E. Bircher.

150. **Suction Hyperemia in Sand Bath.**—Thies boils the sand in a 1 per. cent. soda solution for half an hour in linen bags holding 3 or 4 quarts. The bags are then hung up for a few hours to dry. The sand is then poured on a large pan with removable end-walls. The sand is rendered alkaline by the soda solution and the infected or suspicious lesion, on the arm for instance, is placed in the pan and the sand heaped over it. The capillary attraction of the sand keeps the wound dry, the suction being the greater the finer the grain of the sand. With a spoon the patient keeps putting fresh sand over the lesion. Thies applies these sand baths twelve or fourteen hours a day or longer unless the suction is so great that it cannot be tolerated so long. Burns, leg ulcers, phlegmons and all large open surfaces with inflammatory infiltration, putrid sores and gangrene are particularly adapted for this treatment which is also effectual in treatment of transplanted flaps, first covering the flaps with a piece of chiffon glued to the sound tissues around the flaps. The capillary attraction of the sand is shown by connecting an alcohol manometer with a Berkefeld filter full of water, and standing in a dish of fine sand; the water is drawn through the filter by the sand, leaving a negative pressure in the filter and rapidly sending up the manometer index.

152. **Treatment of Leg Ulcer.**—Bircher has obtained excellent results with the spiral incision running around the leg from ankle to far up on the thigh, according to the technic advocated by Rindflesch. He has applied it in eight cases. The large veins are divided at so many points that the tendency to varices is permanently cured.

156. **Local Application of Iodin in Treatment of Erysipelas.**—Ferrari reviews the history of iodin treatment of erysipelas and reports forty cases in which he has applied it with excellent results. It is important to paint the sound zone around first; then, with a fresh wad he paints the erysipelas patch and covers it with cotton to prevent the patient touching the region and spreading the contagion. He has found it best to apply the iodin lightly five or six times a day, thus preventing the tanning which is liable to occur when the skin is swabbed too copiously with the tincture. He prefers a 10 or 12 per cent. strength and warns that the tincture must be made comparatively fresh, and reiterates that it must be applied from the periphery of the lesion working toward the center instead of from the center outward, which is liable to spread the infection.

158. **Subcutaneous Injection of Phenol in Treatment of Tetanus and Sciatica.**—A number of reports by various writers are here collected, all showing the great benefit from the Baccelli technic in treatment of tetanus and sciatica to supplement local measures. About twenty-five case histories are reported with five of sciatica; the results were favorable in every case.

Riforma Medica, Naples

March 27, XXVII, No. 13, pp. 337-364

166 *Inflammatory Tumors from Migrating Foreign Bodies. (Tumori infiammatori da corpi estranei migrati.) I. Tansini.
167 Reactions in the Urine in Infectious Diseases. (La reazione di Volovskye; la reazione di Butenko.) L. Ferrannini.

166. **Inflammatory Tumors from Migrating Foreign Bodies.** Tansini found a fish-bone in a tumor in the abdominal wall below the navel; the tumor was excised on the presumptive diagnosis of a fibrosarcoma or neoplasm of embryonal origin. In a second case the tumor was in the submaxillary region, was indolent and growing harder, and was about the size of a hen's egg. It proved to be an inflammatory reaction to the presence of a scrap of a grain of wheat in the salivary gland. No giant cells were found in the inflammatory tumor in either case.

THE RÔLE OF DREAMS IN ETIOLOGY *

F. X. DERCUM, M.D.
PHILADELPHIA

Interest in the subject of dreams has been especially stimulated since Freud enunciated his theory. As is well known, Freud claims to be able to unravel dreams by his so-called analytic method, and he further regards dreams as directly concerned in the production of various hysterical symptoms, phobias, obsessions and delusions. In his brochure "Ueber dem Traum," and in his book "Die Traumdeuting," he tells us that he reached new conclusions with regard to dreams when he applied to them the same method of psychologic research which he had previously applied to the solution of various morbid phenomena. It becomes necessary, therefore, in order that we may have clear conceptions, to briefly review the origin and nature of his method.

Psycho-analysis, as is well known, began with Breuer's case of hysteria. Breuer and Freud stated that they found that the individual symptoms of hysteria immediately and permanently disappeared whenever they were successful in fully arousing in the patient the memory of the event which was causal to the development of the symptoms, together with the accompanying emotion, if, added to this, the patient gave the fullest possible description of this event and gave verbal expression to the emotion. Originally this method presupposed that the patient was capable of being hypnotized and was based on the expansion of consciousness which was supposed to ensue under hypnosis. Subsequently formal hypnosis was dispensed with. Freud's endeavor was to set aside the patient's symptoms, and he attained this end in so far as he placed the patient back into the psychic state in which the symptoms first made their appearance. There appeared under these circumstances memories, thoughts and impulses which had long disappeared from his normal consciousness. When the patient communicated these, his "soul happenings," to his physician, and did so with intense emotional reaction, the symptom was conquered and its recurrence prevented. This result Breuer and Freud explained as follows: The symptom had existed as a substitute or in place of another past experience which had been suppressed (*verdrängt*), and the recollection of which had become subconscious—that is, it was a conversion of the original memory of an act and its associated emotion into a pathologic symptom or obsession. The therapeutic efficacy of their procedure Breuer and Freud explained as the catharsis of the repressed, "locked-up" emotion which had been attached to or associated with the suppressed psychic experience. Freud asserts that his method, or the "cathartic method" as it has also been termed, is, in contrast to all other methods of psychotherapy, characterized by the fact that its therapeutic efficacy is not due to suggestion, a statement which the facts attested by Freud himself lead us frankly to question. I need hardly detail the method which Freud employs. Briefly it is as follows: The patient lies on her back on a couch, while he himself sits on a chair back of her and out of her line of vision. He no longer requests the patient to close her eyes as he did in his earlier method and avoids every touch or procedure such as would be in keeping with hypnosis. Such a séance, he informs us, has the character of a conversation between two persons equally awake, one of whom, the patient, is spared every possible muscular effort and every diverting sensory impression such as might disturb her in her concentration on her internal psychic processes.

In order to take advantage of these involuntary ideas or conceptions of the patient, Freud requests the latter to allow herself to drift in her communication, just as one would drift in a conversation in which one passes in turn to the most varied subjects. He enjoins on the patient, before she enters into the detailed account of her history, to tell everything that comes into her head, whether she thinks it important or unimportant, whether it seems relevant or senseless. The patient is especially requested not to suppress any thought or idea because this idea happens to be shameful or painful.

It is with this procedure as applied to dreams that we are in this paper concerned. The essential facts of a dream having been noted in writing or in an oral statement, as the case may be, the individual is to communicate every idea without exception that occurs to her in connection with the dream. Ordinarily a person thinking about a dream will reject this or that idea suggested by the dream as unimportant and as having no connection with the dream. It is this judgment or critique, as Freud calls it, which under ordinary circumstances causes the patient to reject certain ideas from the communication; but if the patient can withhold all judgment or critique in regard to the ideas which present themselves in thinking over the substance of a dream, a psychic material is furnished which leads to the solution or unraveling of the dream. The essential facts of the dream, that is the dream as it is remembered, Freud calls "the manifest dream content"—(*den manifesten Trauminhalt*). The material derived from the dream, i. e., from the unrestrained association of ideas ensuing on a giving up of one's self to dwelling on the dream, Freud calls the "latent dream content." The psychic process by means of which the latent dream content is revealed, he calls the "dream work" or *Traumarbeit*. The opposite psychic process he calls the "analysis work" or *Analysenarbeit*.

---

* Read before the Philadelphia Neurological Society, Feb. 24, 1911.

Further, Freud says that when one compares the number of ideas contained in a dream, as written down from memory, with the number of ideas to which the analysis leads, the dream work reveals that a very great condensation, or *Verdichtung,* as he calls it, has taken place in the dream. It is difficult to form an adequate idea of this condensation. It becomes more apparent the deeper the dream analysis penetrates. We do not find a single factor of the dream content from which threads of association do not lead into three or more different channels; there is no situation which is not pieced together out of three or four impressions and experiences; in other words, Freud evidently regards the dream content as a compound of a number of psychic elements. He compares it to the composite family photographs of Galton. The dream work brings the various apparently superimposed dream components to light. The common factors of the dream content become more prominent, while conflicting details disappear. This explains in part the varying prominence or peculiar indistinctness of so many elements. Where common factors or common elements between the dream thoughts are not present, the dream work endeavors to evolve such in order to make a common presentation of the dream possible. The simplest way to bring thoughts which have nothing in common nearer to each other, consists in the change of the verbal expression for one of them by means of which the other by a corresponding transformation may approach nearer. It is a process similar to that of making rhymes in which the similarity of sound supplies the common element.

Freud believes that through the process of condensation of the dream, we find an explanation of certain features of its content which are peculiar to it alone and are not found in conceptions formed in the waking state. These are the collective and mixed conceptions of persons and the strange mixed pictures, creations and animal compositions, comparable to those of oriental phantasy. In dream compositions they are formed with inexhaustible richness. Every element of the dream content is through the material of the dream thoughts, as Freud puts it, overdetermined, and traces its origin, not to a single element of a dream-thought, but to a whole series of such thoughts. The latter do not stand close to each other, but are of the most varied origins in the thought fabric. The dream element is, in the right sense, the representation in the dream content of all this disparate material.

The analysis reveals, however, another side of the relation between dream content and dream thoughts. Just as from every dream element connections lead to a number of dream thoughts, so, as a rule, a dream thought is represented by more than one dream element. The association paths converge not simply from the dream thoughts to the dream content, but intersect and interweave many times on the way. In complicated and confused dreams, the impression of dissimilarity between dream-content and dream-thought cannot be entirely ascribed to condensation and to dramatization. There is evidence of the working of a third factor. Freud notes that when he, by means of his analysis, arrives at a knowledge of the dream-thoughts, the manifest dream-content deals with entirely different material from that of the latent dream content. This, however, is merely an appearance which vanishes on closer examination, for Freud finds that all of the dream-content is carried out in the dream-thoughts and that almost all of the dream-thoughts are represented by the dream-content. However, there is still a difference remaining. That which in the dream was clearly and plainly marked as the essential content, must be relegated to a very subordinate rôle among the dream-thoughts, and that which among the dream-thoughts has the claim to greatest attention is the representation of material which is found either not at all in the dream content or is only represented there by a very remote allusion in an uncertain region of the dream. Freud expresses this idea as follows: During the dream work the psychic energy passes from the thoughts and conceptions to which it by right belongs, to others, which, in his judgment, have no claim to such an emphasis or importance, and it is this process which has to do with the concealment of the meaning of the dream and with making the connection between dream-content and dream-thought unintelligible. This process, to which Freud ascribes great importance, he terms "dream-displacement" or *Traumverschiebung.* It would seem that that which is most vivid in the dream-content would be the most important, but according to Freud's theory, it is precisely in an obscure dream element that he finds the direct evidence of the most important dream thoughts.

Displacement plays a very varying rôle. There are dreams in which no displacement takes place; these are clear and intelligible dreams, like the dreams of an unveiled or unconcealed desire. In other dreams, again, not a single particle of the dream thought retains its proper psychic value. Everything important in the dream-thoughts is replaced by secondary matter. A most complete series of transitions can be recognized. The darker and more confused a dream, the more we may count on the factor of displacement. Again, when instead of the original elements—instead of the really pertinent material—indifferent material finds a place in the dream-content, we have merely to do with an act of displacement.

Further, the dream-work, or *Traumarbeit,* fashions the preformed dream-content into a dream-composition. The dream acquires a kind of façade which covers almost all, but not all, of its parts. In this portion of the dream-work, motives become apparent, motives which have their origin in a regard for the comprehensibility of the dream.

The kernel of the problem, says Freud, lies in the displacement. The essential condition of the displacement is a purely psychologic one. It is of the nature of a play of motives or activation of motives. We ascertain the cause of this activation of motives when we realize that we are compelled to break off in communicating the contents of a dream because thoughts present themselves which cannot be revealed—cannot be spoken of to others—without the injury of most important considerations, personal and private. Freud asserts that this is true of the content of every dream; that every dream contains thoughts which necessitate privacy. If, Freud says, he pursues the dream-thoughts *for himself,* he arrives finally at thoughts which surprise him, which he did not know existed in him, and which not only appear strange to him, but are also unpleasant and which he, for this reason, would energetically resist. Freud says that he cannot do otherwise than to suppose that these thoughts are really present in his soul-life (his subconsciousness?), and possess a certain psychic intensity or energy, but because they had been in a peculiar psychologic situation, they could not become known to him. i. e., could not reach his consciousness. He terms this condition *Verdrängung,* suppression. He says he cannot refrain from concluding that between the obscurity of the dream content and the condition of suppression, there is a causal relationship, and he concludes that the dreams had to be obscure in order that the tabooed dream-thoughts should not reveal themselves. The misrepresentation of the dream serves to conceal the latter.

Freud believes that the dream-work, *Traumarbeit*, is one of a series of psychic processes to which the origin of hysterical symptoms, phobias, obsessions and delusions are to be ascribed. Condensation and specially displacement are characters never wanting in the other processes as well. Freud believes that a whole train of phenomena of the every-day life of normal individuals, forgetfulness, unconscious mistakes in speech, in simple acts and other errors, are due to analogous psychic mechanisms.

Freud's therapeutic application of the dream consists in having the patient submit himself to the procedure already outlined, i. e., of allowing all of the thoughts suggested by the dream, no matter what their character, to find verbal expression, and, just as in his method of psycho-analysis, the suppressed, painful or shameful thought thus finds a vent. Freud assumes that even in the deepest sleep a certain degree of psychic activity is present which manifests itself as a watchfulness or guardianship over the sleeper. This guardian-like attention or watchfulness concerns itself among other things with a suppressed desire and forms with the latter the dream, the dream being a compromise of this guardian-like attention and the suppressed desire. Thus is produced a kind of psychic relief for the suppressed desire, for the dream represents the desire as fulfilled.

It is to be noted that the feature of Freud's conception of the dream is, first, its personal, intimate nature, dealing with a subject of such a character that the latter cannot be discussed without injury to the dreamer, without lesion of the proprieties, and second, that the dream always deals with a desire. Freud divides dreams as follows: first, those which consist of an unveiled, undisguised realization of an unsuppressed desire; second, those which consist of the realization of a veiled desire latent and suppressed; and third, those which consist of the realization of a suppressed desire, little or but slightly veiled or disguised. The secret, non-communicable nature of the dream and the desire, veiled or outspoken, constitute, according to Freud's theory, the moving factors of the dream.

Freud's theory, though ingenious, and, I believe, unnecessarily involved, challenges criticism from two points of view; first, as to the secret or sexual content which he declares every dream contains; and second, as to his method.

In discussing Freud's theory, as applied to the unraveling of the psychoneuroses, in a paper read before the Philadelphia County Medical Society some years ago, I pointed out that the first criticism—a truly glaring criticism—which offers itself is the peculiar view which Freud holds in regard to the origin of obsessions. Breuer in his first patient, the patient whose case originally suggested the method, fancied or perhaps did detect in the history a cause of self-reproach or blame which had led to her hysteria, and the unloading or confession of which led to her prompt recovery. At any rate the studies made by his colleague, Freud, have led the latter to some very remarkable conclusions, conclusions to which comparatively few neurologists as yet have been able to subscribe. Freud believes that the various obsessions, hysterical and otherwise, have their origin in some passionate sexual action or aggression of childhood. Obsessions are, he says, always reproaches changed or evolved from the suppression of the memory of reproaches having this sexual origin; in other words, the memory of the sexual action itself, being repulsive or abhorrent, is suppressed, but the feeling associated with the memory persists in the mind and now associates itself with or attaches itself to some other memory or action and that in this way arise the various obsessions. Others than myself have dwelt on the glaring inconsistency of the sexual immaturity of children and the intrinsic biologic improbability of this theory. Perhaps Freud has himself been impressed by this fact, for of late years it would appear that he has retreated to the age of puberty, attempting to save the situation, however, by saying that the memory of these sexual events is projected from puberty into the period of childhood. Whether every dream has a secret or sexual content must be left to the sober thought and honest judgment of ourselves and others; must be left to the testimony of human experience in general. As far as my own experience goes, as far as the testimony of those in whom I have studied the subject of dreams goes, I must come unhesitatingly to the opposite conclusion. It is true that dreams with sexual content do occur, that unquestionably they occur in young persons, especially in young men and are no doubt normal accompaniments of sexual evolution; but that all dreams possess this secret content is certainly not in accord with general human experience, any more than it is in accord with our experience as neurologists that every obsession, for instance, is due to the suppressed memory of a sexual aggression in childhood.

Further, it is extremely probable that Freud by his method suggests the memories of sexual occurrences to his patients; in other words, that he elicits from them a fictitious memory of sexual events in their childhood, of events that have never occurred. Indeed, Loewenfeld gives an instance of a patient of Freud who subsequently came into his (Loewenfeld's) hands.[1] The woman stated to him that the sexual events which she had related to Freud when under his treatment had really never occurred. She declared that the whole thing had been a piece of pure imagination.

Not only does the presumption of a secret content in the dream, sexual in character, challenge criticism, but Freud's method of dream analysis is likewise open to criticism, similar to that which we apply to his method of psycho-analysis of the obsessions. The method that he practices for the elucidation of the obsessions is carried out under a condition which is such as to bring about in the patient a state of actual or borderland autohypnosis. He places the patient, let us remember, on her back; she closes her mind to every possible external impression; she lies perfectly still; concentrates her mind on her thoughts; and then in giving her account of her past experiences is expressly instructed to allow herself to drift at will, to tell everything, no matter what, that enters her mind. It is further admitted that the process is very fatiguing. It may be doubted whether conditions more favorable to autohypnotic states could be devised, and the presumption is justified that there is but little credence to be placed in the saying of a patient in this condition. It is extremely probable—indeed certain in cases of hysteria—that under such circumstances the patient will respond with alacrity to the slightest suggestion, inadvertent or unintentional though this may be on the part of the physician. That confession of imaginary sins, especially sexual transgressions, should be made under these circumstances is not to be wondered at.

---

[1] Loewenfeld: Sexualleben und Nervenleiden, 1899, p. 195.

Now the very condition which Freud imposes in the analysis of the dream-content is equally comparable to an autohypnosis, and that under these conditions the material secured is unreliable, is extremely probable. It is presupposed that the mind, in reflecting on the dream, drifts at will without the guidance of what Freud calls the critique—which critique can be freely rendered as the personal equation of judgment. Such a severance of mental function as the conditions of the dream analyses imply, that is, the unrestrained drifting of thought and the suspension of all judgment, is not normal. Such a severance of function implies of itself a state of hypnosis—or a state of mind closely akin to hypnosis, and it certainly seems unphilosophic and unscientific to regard the various mental pictures resulting as representing the undoubted and intrinsic factors of the dream—as representing the essential features and the structure of the dream. There is nothing to justify such an inference, and yet Freud regards it as a foregone conclusion.

It is hardly the function of this paper to enter into a consideration and discussion of the origin and nature of dreams. Suffice it to say, however, that I believe, as does Samuely,[2] that dream conceptions arise just before the sleeper awakens, i. e., just as he is in the act of entering into consciousness. The dream conceptions are part and parcel of the act of awakening. The conceptions furnish the material from which the dream is subsequently constructed. This construction occurs only after waking consciousness has been established. The confused, simultaneously arising dream pictures are then arranged according to time and location, the lacunæ being filled in by the aid of the imagination and reflection. Semi Meyer[3] also believes that the dream history is usually constructed only after the person has awakened. According to Meyer, every dream is something added to the act of awakening. It is a phenomenon dependent on, and is a part of, the act of awakening. There is in every act of awakening an intermediate twilight state of mind, usually very brief, but sometimes prolonged, during which inroads, vague and indistinct, are made on the sensorium from without, and the conceptions thus arising, are, when the patient fully awakens, arranged automatically into some semblance of order and sequence both as to time and space. That long dreams, dreams of complex content and implying long duration of the dreaming act really occupy but a very short period of the dreamer's time has been repeatedly proved. Thus Flux[4] describes a dream in which the period of unconsciousness did not exceed ten seconds, and yet the dream dealt with a shipwreck with all its details, the time necessary for the occurrences being about three and three quarter hours. The truth is that the arrangement of the dream pictures is automatic, begins at once in the act of awakening, and is later often elaborated and dramatized. It is probable that when the awakening occurs quickly, i. e., when the transition to consciousness is sudden and complete, that the dream remains fragmentary. To take such a dream and submit its conceptions to a process, the essential features of which are indistinguishable from those of autohypnosis, may lead to almost any vagary. That the ideas resulting from this method are determined by the personal peculiarities of the individual, by his training, his education and his habits of thoughts; by his desires, his instincts and his sex, goes, I think, without saying; but that one has the right to ascribe to these ideas any value other than this, can be, to say the least, seriously questioned; to go so far as to say that because in one individual dreams usually have, or always have, a sexual content, therefore, we are to conclude that all dreams in all individuals have a sexual content, is, to say the least, not quite logical. To ascribe to ideas which are manifestly secondary abstractions, ideas evolved subsequently to the dream—a causal character, an etiologic value to explain preexisting symptoms, is again not quite logical. To say that the dream analysis of Freud unearths a repressed dream-complex, the unearthing of which gives relief to the patient, is merely to say that the patient dwelling on his dream and induced to speak without hindrance, merely tells the unpleasant, perhaps secret and personal fact or facts of his history which he would have told and constantly does tell without reference to any dream. The danger, however, arises, just as it does in Freud's psychoanalytic method, that the patient will fabricate, involuntarily or perhaps voluntarily, as did Loewenfeld's patient, and recite events that never occurred. Perhaps they are purely fictitious happenings to fill inconsistencies and lacunæ, and yet, arising spontaneously in the patient's mind, may be accepted by the patient as true and find a place among the memories of his actual experiences. Such a patient is, I believe, damaged, just as is a patient who takes away with him after an hypnosis, a persistent suggestion as to fictitious past occurrences.

We are all of us familiar with the relief which patients experience by giving a full account of their symptoms. Sometimes this account, although by no means invariably, embodies the recital of symptoms of a very personal and intimate nature and at such times the recital has all the force of a confession. That the relief of a patient under such circumstances is very great, we all of us know, and we know, too, that a strange and cumbersome procedure, such as is undertaken in a psycho-analysis, namely, the detailed recital of all the events of the patient's life, embodying especially the assumption of active, aggressive and other sexual occurrences in the patient's history, are unnecessary, just as they are painful, distressing and ethically objectionable; surely the dream analysis is alike unnecessary, if it be not, indeed, misleading and futile.

Finally, in the dream analysis, as in the other form of psycho-analysis, both the physician and the patient assume an expectant attitude of mind. The physician already believes, and the patient is involuntarily led to believe, that a cure of the monophobia, agoraphobia or what not, will supervene when a sexual trauma or aggression has been revealed; and it would seem that the more revolting or disgusting the incident unearthed, the greater its power to cure! Surely here is suggestion, involuntary and unintentional perhaps, but none the less suggestion. What also shall we say as to the rôle played by the shame, the self-abasement and the upheaval of the emotions, in the final result? Surely the theory of psycho-analysis commends itself to our understanding as little as does its practice.

Whether dreams ever really play a rôle in the etiology of nervous symptoms must, to say the least, remain an open question. We all know that patients not infrequently awaken from dreams in fright, as witness the familiar example of the nightmare, and yet to ascribe to the nightmare a uniformly sexual character, as does Ernest Jones,[5] is again stretching human credulity beyond the bounds of human experience.

[5] Jones: Am. Jour. Insanity, 1910, lxvi, No. 3.

That dreams are sometimes followed by symptoms, every alienist knows, but even here it is probable that the dream is itself really a product of the already existing psychosis. Such, for instances, are the cases recorded by Santi di Sanctis.[6] Kazowsky,[7] again, describes a case in which a dream of murder preceded the actual commission of a murder. Penta[8] describes cases in which periods of intense excitement of short duration followed dreams and in one of these cases the dream likewise preceded the murder. Others might be added to this list, but it is safe to say that in these cases the dreams were always symptomatic of the preexisting mental disease and in no sense prodromal.

If, in conclusion, we are asked as to the rôle that dreams play in etiology, we are justified, to say the least, in the inference that that rôle is a very doubtful one; dreams are probably always symptomatic and never causal. Finally also, we may conclude that their symptomatic value is of little consequence.

THE SO-CALLED ŒDIPUS-COMPLEX IN HAMLET [*]

JAMES HENDRIE LLOYD, M.D.
PHILADELPHIA

Of all Shakespeare's plays Hamlet is the one which has the most peculiar and abiding interest for medical readers. This is mainly so because of the problem of insanity which it presents. This problem has been as gravely discussed by alienists as though Hamlet were a real person and not a mere creature of the imagination. But in a wider sense the play appeals to the student of mental phenomena because of its psychologic, as distinct from its psychiatric, questions. The most accomplished literary critics have thus propounded many theories, and in Germany a whole body of literature has grown up about this question. To attempt even to enumerate these various theories is out of my present range, and I will merely quote one writer in *Blackwood's Magazine,* who in his despair announced that Shakespeare himself could not have written a regular dissertation on Hamlet—and then proceeded to write one himself. But if Shakespeare could not have given us a satisfactory explanation of the Prince of Denmark's mental state, I can hardly be expected to do so either, and I must beg to be excused from the attempt.

My object is not so much to discuss Hamlet as to discuss briefly a recent theory which has been advanced to explain Hamlet. The task is really not of my own choosing, but I was drafted into it by the council of this society, who must have thought I was peculiarly fitted still further to obscure the subject. They probably did not expect me really to pluck out the heart of this mystery, but merely to demonstrate that there are more things in heaven and earth than are dreamt of in my philosophy.

We have come to an era of what may be called subterranean psychology. We are invited to plunge boldly into the subconscious, the "subliminal," and in these dark underground recesses of the mind to search with confidence for the data practically of a new science. The eagerness with which this call has been answered by all manner of men and women is shown curiously in widely divergent tendencies, in medicine, in literature, and in religion; and as a result we have psycho-analysis, Christian Science, the Emmanuel movement in Boston, and the Œdipus theory of Hamlet as promulgated by Ernest Jones. All these tendencies can be classed together in what may be called the cult of Freud.

According to Ernest Jones the whole mystery of Hamlet is to be explained by the theory of Freud's "repressed emotions." This is his thesis in a nutshell. Hamlet is "suffering from an internal conflict, the essential nature of which is inaccessible to his introspection." In other words, the Prince did not know what it was that ailed him. Moreover, Shakespeare himself did not know what it was; the audience has never known what it was; the commentators do not know what it was; nobody knows what it was but Jones, and he has discovered it by the methods of psycho-analysis, applied to the play after three hundred years.

The nature of this conflict is about as follows: Hamlet as a boy had an intense passion for his mother. This was not what the world in its ignorance calls the natural affection of a child for his mother, but it was distinctly erotic: in short, the first manifestation of sexual passion We are assured that this is not uncommon, and that women of a passionate nature frequently inspire this feeling in their young sons. Jones even quotes with approval Freud's dictum that "the mother is the first seductress of her boy."

Hamlet soon learned, however, that this would never do. The conventions of the world, or of "the herd," as Jones calls it, frowned on such erotic emotions of a boy for his mother; consequently Hamlet early learned to "repress" these emotions. Here, you see, we are at once introduced into the Freudian amphitheater. Hamlet has a great store of "repressed" sexual emotions for his mother, which in time he forgets, but which are ready to assert themselves when the opportunity offers.

As a natural corollary to this youthful experience, Hamlet had developed a feeling of jealousy for his father. But this feeling also he had instinctively "repressed," until it was forgotten, relegated to the limbo of the subconscious; and in its place had even grown up a strong affection for him, as manifested in the play.

This being the state of Hamlet's subliminal mind, all these "repressed emotions" would probably have remained quiescent, deeply buried many fathoms deep in the subconscious strata of his psyche, if it had not happened that his uncle killed his father and promptly married his mother. The effect of this cataclysm was stupendous, and I confess that the psychologic processes as expounded by Jones are from this point somewhat difficult for me to follow, although I have read his paper very carefully twice over. As I understand the psychoanalysis, however, the result was somewhat as follows:

Hamlet had laid on him the task of avenging his father's death, and, as we all know, began that remarkable career of vacillation and declamation which leads no whither, and which constitutes the mystery of the play. Now, according to Ernest Jones, this is all to be explained by the surging up of these old "repressed emotions." Just why or how, I confess I do not see; but we are assured that the thought of killing his uncle, who stands as a sort of rival to him in his mother's affections, sets all this underground machinery to going (if I may be pardoned the term), and that this is so intolerably painful to Hamlet that it paralyzes his will and arrests his hand. The concatenation of events is not at all plain to me, but I give it as accurately as I am able to interpret Ernest Jones. The argument seems to require that there is some deep and obscure association of ideas in Hamlet's mind, which he himself does not recognize, but which evokes from his subconscious memory painful "repressed emotions" which were inspired in him in childhood by his mother, and which were sexual in tone. Whether this is genuine science or whether it is mere vulgar fantasy, I leave to the consideration of others.

---

Ernest Jones calls this the "Œdipus-Complex," a term which he also borrows from Freud, because he sees in it a train of psychologic phenomena similar to what is seen in the old Greek legend of Œdipus. Let us see.

The "Œdipus Tyrannos," one of the two dramas by Sophocles which embody the most familiar form of the legend, is one of the masterpieces of Greek tragedy. The hero is the son of Laius, king of Thebes, and of Jocasta, his wife. An oracle had warned Laius that he would meet his death at the hand of a son of his own; consequently Œdipus at his birth was given by his father to a herdsman to be exposed to die on Mount Cithæron. But the infant was rescued, and was reared by Polybus, king of Corinth, as his own son. When he grew to manhood he was taunted with being a supposititious child, and he repaired to Delphi to consult the oracle. The god warned him that if he returned to his native country he would kill his father and commit incest with his own mother. To avoid this fate he resolved to shun Corinth, thinking that to be his native country. Wandering through Greece, still ignorant of his own origin, he happened to meet his father, King Laius, attended by only a small retinue, and in an altercation he killed the king, of whose identity he was ignorant. At this time a monster, called the Sphinx, sent by Juno to ravage the kingdom of Thebes, proposed the celebrated riddle, on the correct solution of which depended the redemption of the city. Œdipus hastened to Thebes, answered the riddle, and was proclaimed king. To complete the horror of the situation he straightway married the widowed Jocasta, his own mother, both of them being entirely innocent, for they were ignorant of their mutual relationship. By her he had children, one of whom was his devoted daughter, Antigone. He was thus caught in the meshes of an appalling tragedy.

The drama of Sophocles deals entirely with this situation, and unfolds it with all the intensity and concentration which the unities of Greek tragedy had developed into a supreme art. No one can read this drama, even in an English translation of to-day, without being profoundly moved with the simplicity, the pathos, and the accents of an irrevocable doom which speak to us across the long lapse of more than 2,000 years.

There is nothing in this tragedy by Sophocles to invite the modern methods of psycho-analysis. There is nothing in it that I can discover of the subliminal or the subconscious or the play of "repressed emotions." It was contrary to the Greek genius to deal in such obscurantism. All is as clear and as open as day. The audience knew the story well; it was only the hero and his mother who were ignorant of their horrible involvement; and as an acute critic has pointed out, it is this very contrast between the attitude of the audience and the ignorance of the hero that gives to the tragedy a singular note of the irony of fate. When the final revelation comes it comes as with the climax of doom: Jocasta kills herself, and Œdipus puts out his eyes and goes forth a wanderer on the earth, led by the devoted Antigone.

I fail to see in this tragedy any essential resemblance to the situation in Hamlet. The Prince of Denmark was not involved in any mystery arising out of mistaken identity. He knew perfectly who his mother was, and she knew that he was her son. This alone is enough to stamp the radical difference between Hamlet and Œdipus. The theory that Hamlet had any "repressed emotions" of amatory passion for his mother, is entirely gratuitous, and outrages every sentiment of nature as well as every canon of art. There is no expression in the play that I know of that supports such a theory, and it is only by reading it into the play between the lines by a process of artificial psycho-analysis that such a monstrous theory has its origin. It is supported neither by science nor by literary criticism, and of all the theories yet sprung to explain the so-called psychology of Hamlet it is the vilest and the most far-fetched.

The emphasis laid on sexual ideas by Ernest Jones in his paper is highly characteristic of the whole Freudian school. They seem absolutely obsessed with ideas of sex. They cannot get their minds out of this channel; and it would be an interesting test of the value of their own psycho-analytic methods for somebody to turn their guns on themselves, and see to what repressed sexual emotions in their own subliminal strata is due this over-emphasis of a somewhat forbidden subject. Can it be that the whole Freudian phenomenon is a form of sexual neurasthenia breaking out among a class of idealistic men and women with a tendency to scribble?

I do not pretend myself to pose as a critic of Shakespeare, but there are some thoughts which I offer in conclusion, with the more confidence as they are not entirely my own. I do not believe myself that there is nearly as much of a profound mystery in Hamlet as the critics and commentators are disposed to see. They are looking for something which is not in the play, and they have consequently wrapped it in unnecessary obscurity. Mr. Furness, of this city, the most eminent of living Shakespearian commentators, sweeps the whole problem of Hamlet's insanity aside by saying that he was neither insane nor pretended to be insane. It is impossible to classify his insanity, or to make it accord with our scientific ideas.

As a dramatic writer, moreover, Shakespeare had his faults. In common with all English playwrights he ignored the law of unities as observed by the Greek dramatists. A comparison of Hamlet with the Œdipus of Sophocles makes this apparent. The Greek holds the situation thoroughly in hand and goes straight to the climax, but the climax in Hamlet is lame and unsatisfactory.

But in my opinion the most glaring inconsistency in Hamlet is the age of himself and his mother. He is represented as a man of thirty; this at once must place his mother well along in middle life, and yet she is presented as a woman in the full bloom of her sexual charms. This bears directly on the subject of this paper.

All readers feel the fascination of Hamlet. His personality has appealed to men and women far more than any fictitious character in modern literature. I believe this is the keynote of the alleged mystery and of the romance which surround him. His grace, his personal magnetism, his melancholy, his philosophizing, his wit, his princely station and bearing, his love for Ophelia, his unhappy destiny, have all served not only to attract but to dazzle mankind. A discerning critic has said that the deep and permanent interest is in the conception of Hamlet himself rather than in the plot. In other words, Hamlet is greater than the play. No theory is necessary to explain this: it is simply Shakespeare's transcendent poetic art which has presented us with a complex and lovable character.

If Shakespeare had his faults as a technical dramatist, we must remember that he was simply writing for the entertainment of a sixteenth century English audience. He was not writing history, or biography, or science, or metaphysics, and least of all was he indulging in any process of psycho-analysis. Probably no one would be more astonished than he at the theories of Freud and his followers. To take Hamlet and attempt to pump out of him a whole lot of "repressed emotions" of sexual love for his own mother, is not only disgusting, but is no more sensible than to stand by the side of a beautiful marble statue, and, with note-book in hand, to pretend to jot down the story of the statue's subconscious life as imbedded in the depths of its marble head.

Mr. Furness has somewhat tartly said that there has been much commenting on Shakespeare which is a nuisance and a weariness of the flesh. This was even before the appearance of Ernest Jones' essay, or of my present paper.

CHRONIC GLANDERS IN MAN

REPORT OF A CASE: PATIENT TREATED WITH GLANDERS VACCINE. APPARENT CURE

WALTER C. CRAMP, M.D.
NEW YORK

In 1906, C. D. Robin of the Royal Victoria Hospital, Canada, reported 156 cases of chronic glanders, collected from medical literature. Since this excellent review of the subject there have been reported but four definite cases, accessible to me—one by Post and one by Sieur in 1907, one by Dr. A. T. Bristow of Brooklyn, and one recently shown at the New York Surgical Society by Dr. Hitzrot. Several cases of acute glanders have occurred, however, and have been chronicled.

After reading Robin's article and noting his conclusions, drawn from an exhaustive study of his many cases, one is forcibly impressed by two salient facts; first, that chronic glanders in man is an exceedingly rare disease, unless many mistakes in diagnosis are made; second, that the mortality is extremely high, only 6 per cent. of the 156 cases reported being positively known to have resulted in a cure. These two facts alone seem to offer sufficient justification for the publication of the following case, which came under my observation in Bellevue Hospital in the service of Dr. J. D. Bryant, to whom I am greatly indebted for the privilege of studying and recording this case as one of those in which an apparent cure was obtained, the patient remaining free from the disease for a period of eighteen months. No further report of the case is possible, as the patient has returned to his native home.

In presenting this record the rule used both by Robin and Bollinger is employed to differentiate between the chronic and acute form of glanders, namely, the existence of the disease for six weeks or longer. In reporting this case, also, I have refrained from a positive statement relative to actual permanent cure, realizing that it is very difficult to state definitely just when a patient with glanders can be considered cured, as so many of those patients reported as affected, even after many months, and in a few cases after many years, finally succumb to the disease.

This patient, as stated above, had remained free from any symptoms of glanders for eighteen months, was in good health, doing hard work daily, and had also been under close observation. This patient was treated with glanders vaccine, which proved of inestimable value in controlling the disease. The vaccines were made by the New York Board of Health from a glandered horse and kindly furnished to me by Dr. W. H. Park. These vaccines were not standardized, and so the actual number of bacteria is not definitely determined, but estimated at fourteen to twenty million per cubic centimeter. The report of the case follows:

History.—M. M., aged 34, a Pole, a cement worker, was admitted to Bellevue Hospital, Oct. 20, 1908. There was nothing in the family history which could possibly have had any bearing on his illness. The patient's habits were good, he drank four or five glasses of beer daily, ate and slept well, and worked very hard. He was employed in making cement walks; was exposed to wet and cold a great deal, his feet often becoming wet and his clothes soaked by rain. In no way was he ever directly associated with the care or handling of horses, nor was any member of his family. No other member of his family was ill.

Previous Illness.—One year previous to his admission to the hospital the patient had had a "stitch" in his right side. He was ill about one week and made a good recovery, except that occasionally he had a slight cough without expectoration. Generally speaking, however, he enjoyed fair health, working each day and eating well.

Present Illness.—Four weeks previous to admission, the patient's clothing became wet through from exposure and the same evening he had chills and fever, followed by profuse sweating. He had similar attacks three or four times weekly previous to his admission. One week after the first chill, there appeared a swelling over the right forearm, followed the next day by one over the left forearm and right thigh, without any association of pain or tenderness over them.

Clinical Data on Admission.—When the patient entered the hospital he had a temperature of 100.2 F., pulse 120, respiration 24. Blood: Leukocytes, 11,400; polynuclears, 78 per cent.; lymphocytes, 17 per cent; transitionals, 2 per cent; basophils, 2 per cent; eosinophils, 1 per cent. Urine: amber, clear, urinous odor, sp. gr. 1.022, faint trace of albumin; many leukocytes, amorphous urates, and a few hyaline casts.

General Physical Examination.—The patient was of medium frame and poorly nourished; mucous membranes clean, but anemic; pupils equal, reacted normally to light and accommodation; tongue heavily coated, slightly tremulous; pulse regular, of moderate tension. There were a few sibilant râles over base of the right lung; no nasal discharge nor expectoration; inguinal and axillary lymph-nodes palpable; reflexes normal.

Lesions.—Small abscess over radial side of middle third of left forearm; another on ulnar side of right forearm near elbow; another on posterior surface of calf of right leg, five inches below knee, and still another about six inches in length over posterior aspect of left thigh at the middle third. There were no signs of inflammation referable to these tumors and no pain nor tenderness associated with them. These abscesses, which were deeply situated in the muscles, were opened under cocain anesthesia, the cavities irrigated with mercuric bichlorid solution and drainage instituted. The pus was of a chocolate color, fairly thick, with no odor. The report of the findings obtained by examination of the pus is given in full below by Drs. Norris and Pappenheimer of the Pathological Department of Bellevue:

PATHOLOGIC REPORT

"A deep abscess situated on the posterior and outer aspects of the middle third of the right thigh was aspirated with a sterile syringe, about 5 c.c. of pus being withdrawn. Morphologic examination of this pus on smears and in hanging drop revealed no microorganisms.

"Cultures made on slanted and coagulated Loeffler's blood-serum, and on agar tubes, remained sterile after a week in the incubating oven. With this pus two guinea-pigs were inoculated, one subcutaneously, the other intraperitoneally.

"November 7, seventeen days after inoculation, the pig inoculated subcutaneously was found greatly emaciated, and had developed at the site of inoculation an abscess of considerable size, say 3 cm. in diameter. The abscess was incised, and the pus evacuated. Smears made from this pus revealed a few Gram-negative rods, which closely resembled in their morphology the *Bacillus mallei*. Besides these rods of distinctive morphology, there were found a number of involution and degeneration forms, and of globules and round masses, not staining by Gram's method, but taking on an after-stain with fuchsin.

"Cultures made from this pus yielded in forty-eight hours, on slant glycerin-agar, a growth of Gram-negative rods, resembling the glanders bacilli in morphology. With this pus, an emulsion of a glycerin-agar slant was made and inoculated into two large male guinea-pigs, each pig receiving approximately half of the agar culture emulsion.

"The pigs showed a marked and prompt reaction after inoculation, and the morning following the inoculation both pigs were very ill, with hair standing on end, extremely sensitive to the touch, especially on the peritoneum, and with greatly enlarged testicles. The pigs were found dead the following morning, approximately thirty-six hours after inoculation.

"Examination of both pigs showed a diffuse general serofibrinous peritonitis, and the typical exudate on the tunica vaginalis. The organism was found in the exudate of both guinea-pigs in smears, and by culture. The two guinea-pigs inoculated with the human pus were greatly emaciated, and were chloroformed November 13, in a moribund condition, twenty-three days after inoculation. The pig inoculated subcutaneously showed no lesions in the gross beyond the abscess at the site of inoculation in the skin. The pig inoculated intraperitoneally showed a number of well-encapsulated abscesses in the peritoneum and retroperitoneal lymph-nodes, and in the skin at the site of the puncture of the needle, and abscesses of the liver.

"The bacillus which was isolated corresponded in all morphologic characteristics with that of the *Bacillus mallei*. It decolorized by Gram's stain. The cultural characteristics corresponded in every way to that of the glanders bacillus, giving a characteristic growth on potato and blood-serum.

"Microscopic examination of the tissues of the lesions of the two guinea-pigs inoculated with human pus show the typical lesions of glanders, with numerous characteristic bacilli."

A blood-culture made also at this time proved positive.

The patient ran an irregular temperature till Nov. 5, 1908, when he insisted on returning home.

In December of the same year the patient was seen by me, he in the meantime having received treatment in one of theNew York dispensaries. At this time the wounds were all healed and I decided to show him before the Bellevue Alumni Association in February, 1909, but when he was seen again, in January, 1909, two of the old wounds were discharging pus, the patient was having some elevation of temperature, chills and sweats. He was admitted to the isolation ward at Bellevue in this condition on Jan. 22, 1909, with a temperature of 102 F., pulse 108, respiration 24. He had a leukocyte count of 12,000; polynuclears, 78 per cent.; lymphocytes, 20 per cent.; basophils, 1 per cent.; eosinophils, 1 per cent. Staphylococci were found in smear and culture made from pus obtained from arm and leg, but no *Bacilli mallei*. No *Bacilli mallei* were found in the sputum. The agglutination test was negative.

Treatment.—January 29, 8 minims of glanders vaccine were injected into the gluteal region. In six hours the temperature rose from 100 to 104 F., pulse from 88 to 124, the patient had a severe chill and sweat, and there was considerable reaction in the region of the injection. The temperature dropped gradually to normal in three days and inflammation about the gluteal region subsided. This dose was considered too large and so on February 5, 4 minims were injected as before, the temperature rising to 102 F., and the pulse 108.

February 8, 4 minims were again injected; the temperature rose to 105.8 F., with chill and sweat. An interval of five days was then allowed before another injection of 4 minims was made. The temperature rose to 100 F., and pulse to 96.

February 21, 4 minims were injected. The temperature rose to 104.8 F., pulse to 118. About this time the patient was shown at the Alumni Association. At this time his general condition was markedly improved, but there was a slight discharge from the wound in the right forearm.

The patient insisted on going home and was subsequently treated by me at Bellevue Hospital Dispensary as follows: March 1, 1909, 4 minims of vaccine were injected. April 6, when he returned all wounds were healed and the patient's general health was excellent. He was given 4 minims, however, and again on April 20, May 4, May 18, June 4, and June 21, respectively, on which occasions there was very little, if any, reaction to the injection. Subsequently the patient was seen by me at different times, the last time being eighteen months after all his symptoms had disappeared. In October, 1910, in endeavoring to locate the patient, I was informed that he had returned to his native country, and so no further report is possible.

CONCLUSIONS

There are several points in connection with this case and chronic glanders as a whole which I wish to bring forward.

1. Cases of chronic glanders can easily be overlooked unless one is constantly on the lookout for the disease.
2. Multiple abscesses, especially on the extremities, without definite cause, should excite suspicion, as Robin has shown that in 80 per cent. of cases multiple abscesses occur.
3. In this case there was no direct association with horses.
4. The point of entrance of the infection was unknown in this case, no abrasion on the body being present and no history of a wound being obtainable.
5. There was never any nasal discharge.
6. The patient remained apparently cured for six weeks and then showed a return of symptoms.
7. No bacilli were found in the sputum.
8. Extreme exposure to bad weather seems to be a predisposing cause.
9. This case was proved to be one of glanders by laboratory methods and by reaction to the vaccine injections.
10. This patient was apparently cured by vaccine injections.

349 West End Avenue.

CASE OF CHOKED DISK AND PROGRESSIVE BLINDNESS DUE TO SARCOMA OF THE BRAIN

JEROME B. THOMAS, A.B., M.D.
SANTA CRUZ, CAL.

Some years ago I reported in part[1] a case of choked disk probably due to brain tumor. Recently I have heard of the termination of this case in operation and death, and I consider the complete case of enough interest and importance to submit for publication again. In giving the early history of the case I shall draw at length on the original record included in my earlier report.

Patient.—A man, aged 22, first came under my care Dec. 11, 1906, in the clinic of Dr. W. E. Lambert, New York Eye and Ear Infirmary; he stated that two weeks previously he had been "struck blind" at the car-barns, where he was waiting to take out the car of which he was conductor, but recovered the vision of his left eye about five minutes later to such an extent that he was able to take charge of his car for about two hours longer, when he was allowed to go home; he never regained the vision in his right eye. He had had a burning pain in the eyes just after the stroke of blindness, but had slept well that night, and since then had had no pain of that character. His vision at the time of examination was fairly clear but frequently blurred for a moment, giving him a depressing sense of insecurity and of impending blindness. His history previous to the sudden loss of vision was as follows: Three years before, and again, two years before, he had attacks of unconsciousness, epileptoid in character, during the night; one year before he had attacks of transient numbness of the right face, arm, body and leg, beginning in the arm and lasting a few minutes.

---

[1] Thomas, J. B.: Long Island Medical Journal, November, 1907.

Examination.—Right Eye: Total blindness; the optic nerve-head was yellowish gray, raised by swelling about 1 mm. above the surface of the retina; the central vessels were much engorged; there were several bright white splashes of retinal atrophy between the disk and the macula. This eye had probably been blind for several months, but the fact was not recognized by the patient until his other eye failed.

Left Eye: Vision 20/40. The optic nerve-head was raised about 1.5 mm. above the retina, and its borders were blotted out by a yellowish exudate extending into the retina; the central vessels were intensely congested, and the center of the disk was covered by a network of congested capillaries. The whole appearance was that of an acute process as compared with the atrophic changes in the other eye; the field of vision was about normal; both pupils were dilated and reacted to light, accommodation and convergence, though feebly at times; spontaneous oscillations of the pupils made it difficult to determine the pupillary reactions but the results were verified by several examinations made on different occasions.

Possible foci of infection were sought in the ears, nose, and accessory sinuses, but with negative results. An examination of the urine was negative. There were no traces of syphilis, and the patient denied having any venereal disease.

Treatment and Course of Disease.—After about three weeks' treatment with large doses of the iodid of potassium without improvement, the patient was given daily hypodermic doses of pilocarpin, beginning with gr. 1/12, and finally reaching a daily dose of gr. ¼.

Mercury and iodids were given by mouth at the same time. After three weeks of this treatment the patient was discharged from the wards. The exudate about the optic disk was more circumscribed and the central vision was a little more acute, but there still were frequent momentary lapses of vision. The field of vision was moderately contracted.

About Feb. 1, 1907, the headaches became more severe and the patient had occasional attacks of vertigo. His central vision was still 20/40, but he was more often subject to momentary lapses, and his field of vision was becoming ominously contracted. The consensual pupillary reactions were examined carefully on several occasions and found to be positive, though feeble. The tendon reflexes were normal, and the function of the cranial nerves normal: there were no areas of anesthesia, no symptoms of acromegaly; the temperature sense was normal.

Although there were no motor or other localizing symptoms on which to base a diagnosis of cerebral tumor, it was thought justifiable, in view of such marked symptoms of intracranial pressure as progressive choked disk and persistent headache and vertigo, to advise a decompressive operation for the relief of pain and with the hope of arresting the strangulation of the optic nerve fibers of the left eye. Both operation and lumbar puncture were refused.

By the third week in February the frontal headache and attacks of vertigo were still more severe. The patient appeared dazed at times like one awaking from a deep sleep; his vision had fallen to 20/100, and his field was telescopic.

The patient then ceased to visit the infirmary, and I lost track of him until April 10, 1907, when I examined him in Bellevue Hospital, by the courtesy of Dr. Alexander Lambert, in whose wards he had been treated for several weeks. The only trace of vision remaining was a slight and doubtful perception of light when flashed into the macular region of the left eye. He had frequent intense headaches, and vomited a little every day. Both pupils reacted feebly to light; the consensual reactions were doubtful. There was slight, if any, change in the swelling of the optic nerve-head. He was taking 150 gr. of potassium iodid daily for the relief of the pressure symptoms.

Operative Findings.—The patient was soon removed from Bellevue by his parents and the next news I had of him was that he had been operated on Nov. 26, 1907, at the City Hospital, service of Dr. H. D. Collins, to whom I am indebted for the final data in the case. A tumor was found in the cortex of the brain, about 2 inches in diameter, "lying partly in the posterior part of the left frontal and anterior part of the left parietal region." The tumor was diffuse and could not be enucleated. The patient died within a few hours after the operation; no autopsy was permitted. The laboratory reported the tumor as a "large round-celled sarcoma, very vascular."

Although there are several gaps in the history of this case and no post-mortem examination could be secured, it constitutes a valuable unit in the statistics of optic neuritis and brain tumor.

The case demonstrates the value of optic neuritis as a very early sign of brain tumor; it developed in this patient at least four months before the appearance of other distinctive symptoms.

Progressive narrowing of the field of vision in optic neuritis is of evil omen, although the central vision may remain nearly normal and the appearance of the nerve-head show no change. This fact is familiar to the ophthalmologist, but not always appreciated by the general practitioner or the surgeon.

The experience of my patient gives one courage to advise the decompression operation early for the relief of impending blindness before the appearance of motor or other localizing symptoms.

Dr. Saenger, the eminent Hamburg neurologist, said in his address[2] before the American Medical Association at St. Louis in 1910, that he preferred to postpone a decompressive operation until, with choked disk, the vision begins to show impairment. By this I infer that he refers to peripheral as well as central vision. Dr. J. A. Bordley, Jr., of Baltimore, discussing Dr. Saenger's paper and speaking as a collaborator of Dr. Harvey Cushing, said that there was no change in the optic disk with which he was familiar, from the active stage of hyperemia to the later stages of atrophy, in which a decompression operation was not advisable. Dr. J. Herbert Parsons of London, in discussing the same paper, stated that the advisability of surgical interference in these cases, and the time of operation as well, should be determined by the ophthalmologist rather than by the neurologist; for the only palliation in many of these cases is the retention of vision during the rest of the life of the patient, which may last for a period of months or even years. The neurologist is inclined to wait so long for the more definite and convincing focal symptoms that he often delays the palliative operation until the optic nerve fibers are irreparably injured. That such conservatism is unnecessary and is contra-indicated is proved by the experience of our best brain surgeons and the case is strongly stated by Dr. Saenger as follows: "Palliative trepanation of the skull according to the modern standing of surgery, in the hands of a skilful surgeon who has experience in neurologic work, is almost without danger and an extremely beneficial operation, which I should recommend in every case of inaccessible brain tumor, in order to ease the torments of the patient, and above all to save him from impending blindness."

---

[2] Saenger, Alfred: Choked Disk in Its Relation to Cerebral Tumor and Trephining, THE JOURNAL A. M. A., Sept. 24, 1910, p. 1100

Viewing my case history in the light of some of the conclusions reached by Leslie Paton[3] in his study of 400 cases of brain tumor, the following facts may be noted:

1. The tumor was precentral and the accompanying optic neuritis was very severe. Paton concludes that precentral tumors are nearly always associated with a fairly severe neuritis, whereas postcentral tumors are nearly always associated with a moderate neuritis. It is unnecessary to remind the oculist that the severity of the optic neuritis should be judged not so much by the loss of vision as by the height of the swelling of the disk, turgescence of the retinal vessels, the extent of hemorrhages and patches of exudate.
2. The eye on the opposite side of the tumor was first affected.
3. The difference in severity of the optic neuritis in the two eyes could not be noted because the process in the right eye had begun the atrophic stage and in the left eye was at the height of the acute stage when the patient first came under observation. Both the second and third signs as noted above are untrustworthy, according to Paton. In about one-half of his cases a difference in the severity of the neuritis in the two eyes was observed, but the more severe neuritis often occurred on the opposite side from the tumor.

REPORT OF A CASE OF ANENCEPHALUS

D. S. KALAYJIAN, M.D.

PARKER, S. D.

The following report of a case of anencephalus presents some points of interest.

Mother's History.—The mother, white, American, aged 42, was married at 17 and had nine children. Twenty-two years ago, she gave birth to her second child, a hydrocephalous female infant. She stated that she had unusually difficult labors with all her female children.

Present Confinement.—Labor occurred Jan. 29, 1911. On examination I found the abdomen unusually large, the umbilical region being rather flat, and the sides fuller than ordinary. The limbs of the fetus could be felt on the left side. By bimanual examination, a water sac could be felt, filling the roomy vagina and projecting from a partly dilated cervix. Combined version having failed, I anesthetized the patient, dilated the rigid os manually, cut the tough membrane, performed podalic version, and delivered an anencephalic fetus, which lived but a moment after birth. I estimated the amount of liquor amnii at nearly 4 gallons. The third stage of labor was normal. The placenta showed no abnormality, but the umbilical cord was about a foot long, as thick as a man's thumb, and markedly congested.

Description of Fetus.—The child, a female, weighed about 6 pounds and was well developed, except the head, which was hardly larger than a small orange. The external tissues were lacking over a space extending from just above the supra-orbital arch of the frontal bone to the superior nuchal line of the occipital and from the zygomatic process of the temporal bone on one side to the corresponding point on the opposite side. The sunken brain was exposed and showed cherry color through the delicate membrane covering it. The convolutions were very indistinct, except over the frontal lobes, which were elevated, round, and about half as large as a small English walnut. The mouth, chin and cheek, and the lower part of the nose were normal, but the root of the nose was decidedly flat and the eyeballs were protruding. There was a strip of hair about half an inch wide around the neck. Unfortunately no necropsy was permitted.

The case presents the following points of interest:

1. The birth of two abnormal fetuses from the same mother at an interval of twenty-two years, all the other children being normal. Edgar says of hydrocephalus: "It has been observed to occur several times in children of the same mother." I have failed, however, to find any reference to a mother giving birth to a hydrocephalous child at one time and to an anencephalous child at another.
2. Both of the monsters were females. Is this merely a coincidence?
3. A possible relation of hydramnion to anencephalus. J. C. Webster gives anencephalus as an etiologic factor for hydramnion.

REPORT OF A CASE OF BRONCHOPNEUMONIA, SHOWING POSITIVE BRUDZINSKI NECK AND COLLATERAL SIGNS

MARTIN J. LOEB, M.D.

NEW YORK

In view of the cases reported by Brudzinski and Morse, in which Brudzinski's neck sign was constantly absent in all diseases other than those of the nervous system, I believe that the report in my case will be of interest. Before proceeding, however, to the history of the case, I shall briefly describe these signs:

Brudzinski,[1] while trying to test the rigidity of the neck in a child suffering from tuberculous meningitis, observed that flexion of the neck caused the legs to become flexed on the thighs, and the thighs on the abdomen. He followed this observation up in other cases and found this sign to be positive in 95 per cent. of children ill with tuberculous meningitis, and in 100 per cent. of those ill with either cerebrospinal, serous or pneumococcus meningitis. The sign was found to be absent only in the late comatose stage (*état agonique*) of tuberculous meningitis.

Brudzinski found this sign present in one case of mongolian imbecility, in one case of meningism, and in four cases of arrested development. He never found the sign to be positive in any other acute disease, or in normal cases.

Morse,[2] who has examined 400 patients, agrees with Brudzinski.

TECHNIC TO ELICIT "NECK SIGN"

The head is forcibly flexed with the left hand, while the child is lying flat on its back; with the right hand, pressure is exerted on the chest to keep the child from being lifted. If the sign is positive, both legs will flex on the thighs and the thighs on the abdomen.

The identical collateral sign consists in flexing one leg on the thigh and the thigh on the abdomen when the opposite lower member will assume the same position.

With this brief description I shall proceed to the history of my case.

History.—Baby B., aged 9 months, had a normal but difficult birth; no instruments were used. It had been artificially fed since birth. Stools passed twice daily, yellow, no curds. Nutrition was good. Family history is negative. There is a history of scarlet fever (?) three weeks before I saw the child. The infant became suddenly ill on Jan. 27, 1911; the mother observed fever and cough.

[2] Arch. Pediat., 1910, xxvii, 561; Northrup: New Reflex Signs in Meningitis Diagnosis, The Journal A. M. A., Jan. 14, 1911, p. 114.

Physical Examination.—The head was abnormally shaped, the left occipital region sloping downward and being depressed. It had been so since birth. The anterior fontanelle was one-half inch wide; there was no bulging or pulsation. No flatness could be elicited over the skull. The tongue was coated. Prostration was intense. Respiration was rapid, but not accompanied by pneumonic grunt or dilation of the alæ nasi. The pulse-respiration ratio was 2½ to 1. The lips were slightly cyanosed. There was slight rigidity of the muscles of the neck. The chest showed diminished expansion on the left side. There was no dulness, and neither râles nor bronchial breathing, though on the third day small mucous râles and bronchial breathing could be made out in the lower midaxillary region on the left side. The abdomen was not large, was rather soft and flabby. The spleen and liver were slightly enlarged. Heart action was rapid but there were no murmurs.

Reflexes: The pupils were normal and reacted to light; there was neither nystagmus nor ptosis of the lids. Brudzinski's neck and collateral signs were present. Kernig's and Babinski's signs were also present.

All these signs were elicited up to the third day. Between the third and seventh days I did not try to obtain them. On the seventh day the temperature was normal and these signs were no longer obtainable.

The temperature ranged between 102.5 to 104 F.; respiration ranged from 65 to 90 and was irregular; pulse varied from 160 to 200. The child made an uneventful recovery.

THE TREATMENT OF CANCER WITH BODY FLUIDS AND CANCEROUS ASCITIC FLUID

EDWARD H. RISLEY, M.D.
BOSTON

This paper is a report of the work done at the Massachusetts General Hospital, under the direction of the Cancer Commission of Harvard University, during the months from February to September, 1910, inclusive, on the treatment of inoperable cancer with the various normal and abnormal body fluids and with cancerous ascitic fluid.

This line of work was suggested by the results obtained by Hodenpyl of New York, which were reported in February, 1910.[1] The purpose of the present investigation was twofold: (1) to determine whether any curative properties existed in the ascitic fluids of cancerous patients; and (2) to determine what effect the various normal and abnormal body fluids, non-cancerous in origin, had on the cancer patient or his tumor. The theory advanced by Hodenpyl in regard to the action of the fluid in his apparently spontaneously cured patient, was along the lines of other theories of immunity. This theory was that the patient in this case must have manufactured within herself some substance in the nature of an antibody, which was detrimental to the growth of her cancer and which eventually caused its retrogression. Subsequent autopsy in this case, however, showed that the patient eventually died of metastatic cancer not demonstrable during life. Weil, in a subsequent report of the analyses of Hodenpyl's fluid and fluids from other cancerous and non-cancerous cases, was unable to find, by any biologic or chemical test, any antibody or any specific substance in any of these fluids whereby they could be differentiated from one another. The nature of the action of Hodenpyl's fluid on cancer remains, therefore, unexplained. Hodenpyl believed that in his case there was produced a specific antibody for the cancer cell. Whether that be true or not, we know of many cases in which the patient resists the inroads of cancer for many years, and MacKay[2] in England has collected from the literature nearly fifty authentic cases of more or less complete spontaneous retrogression of cancerous growths. Spontaneous retrogressions of various tumors, including cancer, are known to occur, but the process by which this is brought about has not been determined. We can conceive, however, of the production in the body of some substance which acts on the tissues surrounding the tumor so that the stroma necessary to the sustenance of the tumor is made to degenerate, possibly by the development of a connective tissue barrier which cuts off its nutrition, or of a substance which acts as an antibody against the cancer cell or its toxins. It is, therefore, not unreasonable to suppose that the cancer patient, as well as the patient with an infection, can manufacture substances which tend to retard the cancerous process. With this theory as a working basis the present clinical experiments were undertaken.

The cancer patients of one group (the group which comprises the main part of this study) were treated with ascitic fluids obtained from patients with cancer in all stages of the disease. An effort has been made to obtain, as far as possible, ascitic fluids from patients resistant to their disease, with the idea that the amount of antibodies per cubic centimeter of fluid in these cases would be larger than in very active or non-resistant cases.

In a second and smaller group, cancer patients were treated with the various normal and abnormal body fluids, other than cancerous fluids, in order to determine their effect on the cancer patient and his disease. In a third group, untreated patients were watched coincidentally for the purpose of comparison with the series of patients treated with the cancerous and the non-cancerous fluids. With these two classes of controls a satisfactory check could be made on the patients treated by the cancerous fluids. The fluids used in the second series were:

1. Normal blood-serum.
2. Hydrocele fluid.
3. Spermatocele fluid.
4. Ascitic fluid from a case of alcohol cirrhosis.
5. Ascitic fluid from a case of incompetent heart.
6. Pleuritic transudate resulting from broken compensation.
7. Pleuritic transudate: non-tuberculous in origin.

Bile, cerebrospinal fluid and chyle have not been used.

None of these fluids, except spermatocele fluid, which exerted a noticeable stimulant effect, especially on females, has had any beneficial effect on the cancer patient or his cancer so far as observed.

A series of ten patients (later treated with the cancerous fluids) was given a trial of from two weeks to one month with these non-cancerous fluids. The latter were given mostly in large doses so as to get all the effect possible. No local symptoms in the tumors, such as were witnessed with the cancerous fluids, or constitutional reactions, were witnessed even with doses of 60 c.c. of any of these fluids. Normal blood-serum was given only in small doses of from 1 to 5 c.c., and gave none of the phenomena of anaphylaxis. In one or two cases a slight rise of temperature was recorded after the largest doses of fluids and also after a 5 c.c. dose of blood-serum. Leukocyte counts were not recorded in this series. It is conceivable that a continuance of the largest doses over a longer period might produce some constitutional reaction. As no beneficial results were seen in the cancer patient or his tumor after one month, this series was discontinued, as it seemed reasonable to suppose that the time was sufficient for the appearance of some favorable or unfavorable symptoms.

[2] Brit. Med. Jour., July 20, 1907. Also Wells, H. G.: The Resistance of the Human Body to Cancer, The Journal A. M. A., May 29, 1909, p. 1731.

For the main part of this work the following cancerous fluids have been used (they are designated in this paper by the patient's last initial):

1. "T" fluid, obtained from Mrs. G. M. T., aged 79, whose mother died of cancer; five brothers died of tuberculosis. Patient had had many febrile diseases. Four months ago she had gastric distress, pains later, vomiting with gradual increase in size of abdomen; much loss of weight. On examination, patient showed cachexia; glands above clavicle, in axillæ and groins; abdomen slightly distended, mass 3 by 4.5 cm. in epigastrium, tender, shifting dulness in flank. Patient was tapped; 3.580 c.c. alkaline fluid obtained, sp. gr. 1,011; albumin 1.6 per cent; culture, negative; slight tinge of bile. Small lymphocytes 78 per cent.; large lymphocytes 16 per cent.; polynuclears 5 per cent. Wassermann reaction, negative. Clinical diagnosis, cancer of liver.

This fluid was the most effective in producing sloughing of tumor masses. Whether this was due to the small content of bile we are unable to state. (The later use of a non-cancerous fluid with large bile content produced practically no sloughing.)

2. "K" fluid, obtained from M. K., aged 53, who had two brothers; one sister died of tuberculosis. For three months, patient had had pain in abdomen, vomiting, loss of weight (25 pounds) and increase in size of abdomen. On examination, liver edge was not felt; abdomen was tense; fluid wave present; edema of legs up to knees. After tapping, nodular masses size of hen's egg and larger were felt all over the abdomen; large mass in left pelvis. By tapping 4,000 c.c. clear dark-yellow fluid were obtained; culture, negative; Wassermann, negative. Clinical diagnosis, general abdominal cancer, active.

This fluid has been practically inert.

3. "L" fluid, obtained from Mrs. K. L., aged 28, who was operated on five years ago for malignant disease of right ovary. May, 1910, patient was in fair flesh and general good condition, but had to be tapped every four weeks. There was a hard, lobulated, slightly tender mass size of grapefruit in right lower quadrant. Fluid was pale yellow; sp. gr. 1,010. Culture, negative. Wassermann, negative. Clinical and pathologic diagnosis, malignant papilloma of right ovary.

This fluid has been valuable in relieving symptoms and retarding the growth of several cases.

4. "P" fluid, obtained from Miss E. P., aged 31, who had an operation in June, 1901, for abscess of right ovary; 1908, repair of hernia in scar. At this time a small mass in right pelvis was felt but was undisturbed. May, 1909, the abdomen began to swell again. July, 1909, the malignant ovarian mass was partially removed; patient made a good recovery. Patient was then in excellent general physical condition; in good flesh, up and about everywhere, but had to be tapped every four to six weeks. Fluid was dark yellow, slightly viscid; sp. gr. 1,024; culture, negative; Wassermann, negative. Clinical and pathologic diagnosis, malignant papilloma of ovary.

This fluid is from the most resistant type of case and produces marked reactions. It has been especially effective in several uterine cases in checking hemorrhage, and in other cases in stopping pain and has seemed to produce more retardation than any other fluid used.

5. "H" fluid, obtained from Mrs. H. H., aged 58, who had, for several months in 1905, right-sided abdominal pain with gradual increase in size of abdomen. Operation in November, 1905, revealed a right-sided malignant ovarian mass which was partially removed. Patient made an uneventful recovery, gained weight and seemed in perfect health until about April, 1910, when she began to have symptoms of increasing constipation, but no pain, loss of weight or change in size of abdomen. Physical examination was negative. At operation, May 17, 1910, recurrent papillomatous mass was found with a little free brownish fluid. Fluid was brownish, watery, sp. gr. 1,010; slight blood content; albumin, 2 per cent; culture, negative; Wassermann, negative.

This fluid seems to have had a decided retarding effect. Not enough was obtained, however, to last more than for two months' treatment. But it was from one of the most resistant types of cases and probably had some specific effect.

TECHNIC

The peritoneal cavity was in each instance tapped under sterile precautions and the fluid drawn off into a sterile bottle and put on ice until used. No standardization was attempted and no preservative was added. The following precautions were taken before the fluids were used: 1. A culture was taken to prove them free from bacteria. 2. A negative Wassermann reaction was required from the patient from whom the fluid was drawn. 3. A series of injections was given to cancer mice to prove that the injections were in no way harmful to administer to human beings. Daily injections of 5 minims of each fluid were given subcutaneously to different series of cancer mice. These were large doses for mice. If no harm came to the mice, and none did, except in three instances, which were due either to a fault in the technic of injection, or to a contamination of the fluid with bacteria, which occurred in one case, the fluid was then used on human beings. These precautions were considered necessary before the institution of this form of treatment, for we were dealing with an entirely new experimental fluid of unknown potency and content, and every safeguard should be used before subjecting even the hopeless cancer patients to its influence.

The fluid had no apparent effect on the growth of mouse tumors.

The patients treated all had inoperable growths, either primarily so or because of recurrence or metastases. All grades of the process have been treated. No case was refused because the process was too extensive, for we wished to get our data from unselected cases; hence, the work has been largely with decidedly unfavorable cases. The patients have been treated as out-patients, reporting three times a week for injections. Fourteen of the cases have been treated as house patients, with large daily injections, for periods of one to two weeks at a time. The clinical diagnosis was unquestionably cancer in every case. In all but three this was confirmed microscopically. In all, forty-five cases have been treated.

The injections were given in four different ways:

1. Subcutaneously in the skin of the abdomen or breast, rather removed from the local disease, in large doses.
2. Subcutaneously, as near the tumor as possible, in large doses.
3. Into the substance or base of the tumor in small doses.
4. Remote from the tumor in small doses.

The dose varied from 5 minims, for the small dose, to 50 c.c. for the large dose; the usual dose, which was given regularly in most cases, without producing either local or constitutional reaction was 15 c.c.

Patients varied noticeably in susceptibility, some getting constitutional reaction with 10 c.c., while others got no reaction with 50 c.c. This variation seemed to be due more often, however, to the nature of the fluid than to the patient. Reaction at the point of inoculation varied from none at all to a temporary redness, soreness and even induration, lasting from twelve to twenty-four hours. In obese patients the reaction was usually marked. No abscesses ever developed. Local hyperemia and some swelling practically always occurred in the tumor itself immediately following the injection, and lasted a few hours, whether the injection was at a distance from, or near to, or into the tumor. It seems to me that this one fact speaks more clearly than anything else for the specificity of these fluids. The fact that a definite local reaction in the tumor itself can be produced within a few hours after injection by a substance injected at a distance from the local disease, indicates strongly the existence of some specific substance in these fluids, which acts on the tumors themselves. The exact way in which this action is brought about and the nature of the substance causing the effect, we have not been able to determine. It is hoped that further biochemical investigation may be able to throw some light on this important point. Constitutional symptoms varied from slight headache to general malaise, chills and fever, nausea and, rarely, vomiting. The temperature seldom went above 102 F. in any case, although large doses occasionally produced a higher rise. A temporary leukocytosis developed in the cases with the most marked reactions. Urinary analyses showed in no case any evidence of an acute nephritic condition being started up. Acute nephritic conditions have been reported by Beebe in New York, and a routine urinary examination should be made as a precaution in all cases under this form of treatment. The patients were started on 3 to 5 c.c. and increased at each injection up to 50 c.c., if well borne, except in those cases in which it was the intention to keep the dose small.

The following histories give the course of each case in detail.[3] Some patients reported very irregularly, while others were allowed to rest from treatment from time to time in order to observe the effect, after a certain number of doses.

Case 1.—Mr. C. S., aged 61, had a growth which appeared one year previous to examination, as a small dull-red lump the size of a marble over mid-sternum, which was cauterized repeatedly, but grew steadily larger, and ulcerated, with much pain. At examination, patient was a large-framed, nervous old man, with ruddy color. Over mid-sternum was an orange-sized, fungoid, ulcerated, protruding mass with depressed center and cauliflower edges. X-ray showed extensive involvement of sternum. Pathologic diagnosis was cancer. February 21 to March 29, 1910, Coley serum was given up to 3 minims at a dose, with no improvement or change; much pain. April 1, 1910, patient was started on "L" fluid (cancer of ovary of five years' duration) and received 25 c.c. every other day till April 11, then 50 c.c. daily up to June 1, 1910. The first five doses caused softening of the edges and increase in discharge and later a marked filling up of the ulcer in the center took place so that bone could no longer be felt at the bottom as before, and no increase in size of the tumor was noted. The patient had to take large doses of opium, however, to control the pain, which was present all the time. A large gland developed in the right axilla after about two months, and the patient very slowly became more feeble; but the original tumor seemed to have been checked in its growth and to have remained at a standstill for the three months the patient was under treatment. June 1, 1910, the patient contracted a severe "cold" and has not reported since.

In this case retardation seemed to have been effected for nearly three months by large doses of fluid from a fairly resistant type of case.

Case 3.—Mr. W. T., aged 52, had cancer of upper and lower jaw; submaxillary gland on the left was the size of a marble. Two similar masses along ramus of jaw on left and smaller nodule above one molar tooth on upper jaw. Clinical diagnosis was cancer. March 17 to 25, three doses of 2 c.c. hydrocele fluid were given, with slight increase in size of nodules. March 29 to April 23, ten doses of 25 c.c. of "L" fluid (cancer of ovary, five years' duration) were given; injections were always followed by local hyperemia in tumor, sometimes slight bleeding of gums and marked constitutional reaction with chill, headache and increase in pain. "T" fluid (cancer of liver with bile) was tried but produced such marked constitutional reaction and swelling of neck that it was stopped, and from April 25 to May 23, thirteen injections of "P" fluid (cancer of ovary, nine years' duration), were given with rapid increase in size of tumor of jaw, which on May 0 pointed and broke, discharging small bits of cancer tissue. May 23 treatment was discontinued at patient's request, as he was having much pain.

In this case neither hydrocele nor the two fluids from the most resistant cases accomplished anything at all, but rather seemed to hasten the rapidity of growth. The patient gradually grew weaker and died Sept. 1, 1910, with no change for the better.

Case 5.—M. D., a man aged 58, had an epithelioma of the leg excised in 1908. There was recurrence in the parotid within eight months. Pathologic diagnosis, cancer; rapid growth occurred after several partial removals; ulcerated. The patient was treated for four months with large doses of x-ray. Face swollen, lips protruding, drooling; large, red, deep ulcerated area replaced whole parotid region and right upper neck and cheek. Abundant discharge. April 9, 1900, 15 c.c. "L" fluid (cancer ovary, five years' duration), followed by marked local reaction in tumor evidenced by acute swelling, increase in discharge and excessive pain. April 21, patient entered ward and kept under the influence of morphin while nine injections of 50 c.c. each of "L" fluid were given, resulting in a marked increase in the discharge of serum and tissue from the ulcer, but no improvement in the condition. In this patient pain was so excessive that treatment could not be continued. It is suspected that the previous use of such large doses of x-ray was an influencing factor. The patient declined rapidly and died six days after the last treatment. This was an extensive, rapidly-growing case and the patient received absolutely no benefit from the serum except the increased discharge.

Case 6.—Mrs. N. G., aged 56, two years ago had a lump in the right axilla opened and removed; the wound never healed. Examination showed an indurated, puckered scar in right axilla, with red edges and sinus. Piece removed proved to be cancer. The breast showed no lumps or indurated areas. There were two hard glands the size of English walnuts above right clavicle at edge of sternomastoid. From April 12 to May 11, thirteen injections of "K" fluid (carcinomatosis of abdomen) were given, with cessation of slight discharge from sinus, and occasional very painful heavy condition of the breast following the injections. March 14, 1 c.c. "T" (cancer of liver with bile) fluid was injected directly into most indurated part of tumor, with resulting renewal of discharge from sinus and slight increase in size of tumor mass. This was a slow-growing condition and practically no change was noticed except those relating to the discharge. The glands in the neck, however, seemed to have grown considerably smaller. Patient was still under treatment at time of this report. There was practically no change from April to August 1, when patient stopped coming for a month. She was seen Sept. 20, 1910, when the mass in the axilla had increased 1 cm. in size; the corresponding arm was much swollen and the patient had lost considerable weight. In this case retardation lasted nearly four months. Jan. 1, 1911, patient was much emaciated and had involvement of lungs.

Case 9.—Mr. C. H. A., aged 70, had an infiltrated, ulcerated epithelioma of right jaw removed October, 1909. November, 1909, dissection of neck was done, with removal of internal jugular vein for rapid recurrence. Examination April 16, 1910, showed portion of lower right jaw missing. There was a small pea-sized ulceration at mid-scar, slightly nodular along scar; a more prominent nodule just under the ear. Pathologic diagnosis was cancer. General condition was excellent. April 16 to May 28, sixteen doses of 5 minims each "T" fluid were injected directly into various nodules in scar, with marked alleviation of pain and slight softening of nodules, and until May 28 the patient showed marked improvement; the recurrence, which had been very rapid before, seemed to be completely held in abeyance, but on May 28 it was found that since May 23 a hard mass had developed under the molar in the right upper jaw. This case was evidently retarded for over a month by the use of "T" fluid (cancer of liver with bile), but suddenly, as in Case 8, flared up after a considerable period of quiescence. Patient stopped treatment June 3, and died July 7, 1910.

---

[3] On account of the length and number of the case reports not all of them have been included in the paper as printed in The Journal, but all will be found in the author's reprints. Those selected here illustrate the various phases of the subject.

Case 11.—M. F. W., aged 34, had a growth which appeared November, 1909, as a lump the size of a small marble under skin on right side of neck. January, 1910, the lump became ulcerated. No treatment was given. Examination showed orange-sized, hard, slightly red, tender mass under right parotid, with three ulcerated areas exuding pus. Ulcers were not continuous. Breath was foul. Patient was unable to open mouth, which was sore inside. Pathologic diagnosis was cancer. From April 21 to May 31, eighteen injections were given, averaging 25 c.c. each, of "T" fluid (cancer of liver with bile). The first injection of 3 c.c. caused extensive sloughing and moderate hemorrhage. The next three injections were followed by increase in pain also. After six injections the growth was breaking down fast and after ten, large pieces of tumor tissue dropped away. This extensive sloughing plus a mild injection throughout the mass caused much pain, sore throat and a very disgusting condition. Daily dressings were done by a district nurse, but even they did not control the profuse, bloody, very foul discharge. Patient was getting very feeble. The tumor had increased about double in size up to one week prior to report, since when it remained stationary. In this case the fluid undoubtedly caused a more marked and rapid breaking down of the tumor-cells. A fluid with small content of bile was used. The patient discontinued treatment June 7 and died June 14, 1910, without any relief.

This is the case in which the most marked sloughing was produced.

Case 13.—Miss E. P., aged 31, was the patient from whom fluid "P" was taken. Operation was performed in 1901; drainage of abscess (?) of ovary, probably malignant. In 1908 a second operation was done: repair of hernia in scar. Small mass in the right lower quadrant of abdomen was not removed. A third operation was performed in 1909: partial removal of malignant right ovarian mass. Pathologic diagnosis was papillary adenoma. April 22, 1910, patient was in excellent general condition; had had no loss of weight; in fact, had had some gain lately. Color was good. Patient was about everywhere; she suffered no inconvenience except that she had to be tapped every four to six weeks. There were bilateral, grapefruit-sized masses in each lower quadrant. April 25 to May 9, ten injections of 50 c.c. each of her own fluid were given subcutaneously, with no reaction of any kind. These were daily injections. After leaving the hospital patient had biweekly injections of her own fluid, and remained in excellent condition; tappings were more frequent and the mass in the pelvis seemed more pedunculated and smaller. Further operation for removal was advised. Patient was operated on in October, 1910, and mass practically completely removed. Patient had had no return of tumor or fluid by Jan. 1, 1911, and seemed in perfect health.

This was an interesting case, in which the patient was apparently benefited by reinjections of her own fluid. This case seems to illustrate the benefit of giving of autogenous serum.

Case 14.—Mr. F. C., aged 60, for two months had had a swelling of the gum of the right lower jaw. Teeth were removed without relief. Examination showed swollen, indurated, nodular, slightly ulcerated gum of right lower jaw from angle to median line, pushing the lip forward, with marble-sized glands under jaw. Patient's general condition was good. May 13, 1910, 15 c.c. "P" fluid (cancer of ovary, nine years' duration) were given, followed by no symptoms. May 18, a loose piece of the cancer tumor was excised and transplanted under skin of left breast. Pathologic diagnosis was epithelioma. May 31, no "take" had been effected and patient was again started on the fluid. Tumor was increasing rapidly.

This transplantation experiment was tried in the hope that if the transplant could be made to grow it might retard, as Gay has found in mice, the original tumor. Patient reported irregularly up to August 1, but was gradually losing strength and the growth increasing in size.

Case 15.—Mrs. I. M. Q., aged 34, had a growth which appeared in the left breast, just outside the nipple, three and one-half years previous to admission, as a lump the size of an egg. Nine months later patient had her last child, but there was no milk in left breast. The tumor broke through skin one year previous to admission but never discharged. No treatment was given. Examination showed a tumor the size of a fist, hard and nodular, with dry ulcerated area the size of a quarter in the left lower quadrant of the left breast. There were many large glands in axilla and above both clavicles; a small septic area at the top of the mass about to break, which did break after first injection. Patient had doses of 20 c.c. "L" fluid (cancer of ovary, five years' duration) with marked reaction at site of injection in the form of a hard, tender lump and heavy breast, with much pain after many of the injections. Patient's general physical condition was excellent at the start. May 10, 1910, the breast had become much softer under treatment and the ulcerated areas discharged more profusely. Since August 1 patient had had but one injection and the breast meanwhile became much harder again and the ulcerated areas dried up. The fluid evidently had a specific action in this case, as shown by the marked softening while under treatment. It was a slow-growing case and little change was noticed other than the softening during the four months of treatment. Jan. 1, 1911, patient was still alive but had metastasis in right tonsil and was beginning to fail and to show evidences of metastasis in the brain. Patient died Jan. 13, 1911, with typical symptoms of brain tumor.

Case 17.—Mrs. M. N., aged 42, six years prior to admission had a lump appear in the left breast, which was "drawn" by a quack. Three years later it returned. Quack treatment was continued. Six months prior to admission another lump appeared in the right breast. Examination showed almost complete solidification of both axillæ, and both sets of pectorals with cancer nodules; both breasts were ulcerated and dry; the left the size of one's palm, the right the size of a half dollar. Patient was in excellent general health; color very good. May 14, 1910, to May 31, patient received five injections "P" fluid (cancer of ovary, nine years' duration) with decided relief from pain; slight constitutional reaction with first two doses. There was no increase in discharge. The fluid acted as a tonic. The ulcers cleaned up materially. The patient's health was still good after four months' treatment. This was a slow-growing process, but seemed to have been benefited. Patient reported Jan. 1, 1911, that she was well except for "rheumatism," and that there then had been no change in her breast at all.

Case 19.—Mrs. L. J., aged 48, a widow many years, had had two children and two miscarriages; there had been much laceration. Three months prior to admission leukorrhea appeared, which became foul, and one month later pain in back and vagina developed. Examination showed foul discharge; vaginal vault extensively indurated; cervix nodular, hard, fissured. Patient's general condition and color were excellent. May 5, 1910, cautery and curettage of cancer of cervix was done. Pathologic diagnosis was cancer. Treatment was started May 23, 1910. Patient was very obese and had several severe local reactions at site of injection, but immediately after treatment was instituted the flowing and pain ceased and the discharge at first became increased and later decreased. Sept. 27, 1910, patient was still in excellent condition, had no pain, but considerable discharge from a process which was slowly enlarging and extending to rectum. In October, 1910, patient had suppression of urine from blocking of both ureters. She entered hospital, had ureters catheterized, but was discharged against advice, to be taken home by sister to die at home. She has been lost track of.

The most noticeable effect of treatment in this case was the cessation of pain and hemorrhage.

Case 27.—Mrs. E. W., aged 49, widow, had a "lump" in the front of her neck for ten years. Operation was performed in 1908 for carcinoma of thyroid. Pathologic report was cancer. There was almost immediate recurrence. On examination was found to be short and stout; general condition good; no cachexia. There was a hard, purplish, indurated, nodular mass involving whole thyroid region, slightly more prominent on left, reaching to below sternal notch and up to right parotid and right tonsil: with many small glands surrounding: a very extensive process. There was a slight numbness of right arm; no pain. July 5 to Sept. 30, 1910, patient received "P" fluid. After the third injection the tumor mass became much softer, and after two more injections the purplish color disappeared and the skin took on an almost healthy color. It was impossible to give this patient over 10 c.c. doses, as she got violent constitutional reactions from larger ones. She left off treatment for one month and during that time the old tense purplish color came back and the stony hardness of the mass. Considering the rapidity of growth before treatment it seems certain that the fluid had caused some retardation in this case.

CASE 31.—Mrs. C. B., aged 56, widow, had always been well until January, 1910, when she had pain when she sat down. The coccyx was removed and hypernephroma, extending to sacro-iliac joint on left, found and confirmed by pathologic examination. Five weeks prior to admission a lump appeared in the buttock. There was no pain, but discomfort on sitting. Examination showed a large-framed, obese, red-nosed woman, with poor superficial circulation, acne rosacea of face, and red scar 1½ inches long at base of sacrum; no nodules in scar. There was a hard, firm, slightly lobulated mass in right buttock, apparently springing from deep structures; no tenderness; rather tense. Pelvic examination was negative. A mass 4 by 6 inches was indefinitely determined. July 5, 1910, to Sept. 30, 1910, 15 c.c. average doses of "P" fluid were given with very slow growth of tumor to 8 by 8 inches, but considerable softening in tumor. This patient had marked local reactions after injections and numerous constitutional reactions, so that fluid could not be pushed to a high dosage. The only noticeable effect was the very slight softening in the mass following injections. The process later was growing more rapidly. From Oct. 1, 1910, to Jan. 1, 1911, the tumor grew only very slowly. At the time of this report it measured 9 by 9 inches, but was slightly harder. The patient was able to take 50 c.c. at a dose of the fluid and had no pain. The patient's condition was excellent.

This case proved to be very interesting, and a condition which gave no promise for relief has been greatly retarded.

CASE 36.—Mr. J. N. W., aged 56, had a growth which appeared twenty years ago as a small, hard pimple back of left ear and broke out and healed up off and on for five years; fifteen years ago patient had it "drawn" by a "quack." Operation was performed August, 1909. The epithelioma was excised and a plastic operation done on the ear. The growth recurred in September, 1909. The patient had *x*-ray irregularly afterward; had Coley serum for five months with gradual slow increase in ulceration under unsettled diagnosis. Pathologic report finally settled the lesion as epithelioma. Examination showed a spare, "wiry" man in excellent health and good color; lobule of left ear absent; crescentic ulceration around base of ear and partially healed ulceration nearly surrounding whole ear; slight ptosis of left lower eyelid. July 16 to September 30, patient received doses of 10 c.c. each of "P" fluid, with increased discharge from ulcerated surfaces at first, followed by slow cleaning up of ulceration, which then looked much cleaner and more healthy than before. General health was still excellent. In October all of the ulcers above the ear were hard and covered with skin. In November ulceration started in below the lobe of the ear and has been growing slowly ever since, and the last four or five injections had seemed to hurry up the destructive process so that on Dec. 31, 1910, the patient was advised to omit treatment for a month. Facial paralysis became complete on left side. Jan. 20, 1911, process had not spread further and there were islands of scar tissue present in several places. February 1, more scar tissue. Considerable reparative process going on.

CASE 37.—Mr. A. S., aged 58, had syphilis in 1879; was treated off and on for ten years with no resulting symptoms. One year prior to admission a small crust formed on the left side of the neck back of and below the ear; there was no ulceration until six months prior to admission, since which time it ulcerated and gradually spread and grew deeper. There was some pain. On examination the patient appeared well developed and nourished; a slightly pale man, and husky voice. There were old brownish scars over the legs and back. On the left side of the neck, back of and below ear, was an ulcer ½ to 1 inch deep, with ragged edges, but fairly clean, 2½ by 3½ inches across; edges not much undermined. The sternomastoid muscle and several small vessels and nerves were exposed in the bottom of the wound. There were small whitish epitheliomatous-looking patches in bottom of ulcer. Pathologic report was epithelioma, without doubt. July 16 to September 30, the patient received *x*-ray and "P" fluid in small doses twice a week with no change for the better, but with gradual deepening of the ulcer under the ear. The ulcer was clean, no hemorrhage. Complete facial paralysis on left side slowly developed and patient began to look a little paler, and was getting weaker. This patient had normal blood-serum for one month before the "P" fluid was started. No effects were noticed constitutionally or locally from biweekly injections of 1 c.c. blood-serum and certainly the "P" fluid, in small doses, has had no effect. During November and December, 1910, large doses, up to 50 c.c. were tried, but the process went swiftly on, causing an almost complete anatomic dissection of the neck down to the vertebral column. The patient's condition, however, did not suffer much and it seems as if the large doses of fluid had stimulated and nourished him considerably.

CASE 39.—Mrs. A. C. C., aged 41, had had no children or miscarriages. For five months prior to admission there was a gradually increasing vaginal discharge, not especially foul. The catamenia were not much affected. Three weeks prior to admission patient began to be very constipated and abdomen became bloated with gas. She vomited repeatedly, and had very little relief from enemas. She noticed that the uterus was lower down than normally. The patient was a small, dark-skinned, very thin, sallow woman, with pulse poor, abdomen distended, visible peristalsis, no masses. On vaginal examination the cervix was found low, hard, and with an ulcer with ragged, raised edges; the uterus was increased in size and almost completely obstructed the rectum. The patient was relieved from this attack of obstruction by one week in hospital; she went out in very poor condition. July 29, 1910, to September 30, biweekly doses of "P" fluid were given with several severe reactions, but rapid improvement in general condition, lessening in discharge and pains and gain in weight. This patient was started on four doses of 5 c.c. each of spermatocele fluid, which produced a marked stimulating effect. The cancer was slowly growing and ulcerating more rapidly, but the general condition had improved from almost *in extremis* to be very good indeed. From September to October 30, the condition remained about the same but the tumor continued to grow until the mass almost completely filled the pelvis, shutting off the rectum and nearly shutting off the bladder. Patient's strength continued good and she had little pain. The serum has been of very doubtful benefit in this case, although it seems as if the stimulating effect of large doses may have kept up her general physical condition.

CASE 40.—Mr. C. H. M., aged 59, several members of whose family died of tuberculosis, had fever and ague at 18. For thirty years patient had a tumor and a sore on the right side of neck posteriorly, which ulcerated fifteen years ago, was excised once, and "drawn" six or seven times. His voice was hoarse since October, 1909. Examination showed a tall, spare, husky-voiced man, with good color; head slightly bent to left; sternomastoid on right tense. Over an area the size of a silver dollar was a hard indurated-edged ulcer with fairly clean base and granulations. Several surrounding nodules and the tissues around for 1 or 2 inches were hard and contracted, most of which seemed to be scar tissue, but some of which was typically cancerous. Examination of the larynx showed right vocal cord in cadaveric position, and paralysis of right recurrent laryngeal nerve, from presence of the disease, probably. July 27, 1910, to August 3, as house patient, he received large daily doses of "P" fluid, with severe constitutional reaction after the last two doses, but practically no change in the local condition, except, perhaps, a little softening of the edges, but with continued relief from the pain in the brachial plexus which had been complained of. August 3 to September 30, 25 c.c. of fluid were given once a week with little change, except that the ulcer seemed cleaner. This had been a very slow-growing process, and aside from the permanent relief from pain showed no change after two months' treatment. On Jan. 1, 1911, patient was admitted to the hospital and the ulcer curetted and skin grafted, with relief of pain.

Case 43.—Mr. R. W., aged 66, had always been well until two or three years prior to admission, when a lump appeared on the side of the neck and grew slowly. It was excised several times; excision with a plastic operation was done June 1, 1910. Since then patient had a recurrence of what examination showed to be epithelioma, and much pain, which required a grain of morphin a day to control. June 23 to July 30, 5 c.c. doses of "P" fluid were given every day, with complete relief from pain, but with increase in discharge and spreading of process. Letter from wife September 30 stated that patient had not had the serum for nearly six weeks; he had gradually failed in strength of body and mind and was expected to live only a few weeks. The process had spread all over the jaw, several sinuses led into the mouth and the patient was in a pitiful condition. The only benefit in this case, therefore, was complete relief from pain while under the serum treatment.

Case 44.—Miss F. H. S., aged 50, had an operation June, 1909, for carcinoma of left breast, three months after appearance of a lump near the nipple. There was recurrence in the scar after nine months. Examination showed a strong, large-framed woman in excellent health. There was a ¾-inch linear, red recurrence in mid-scar; no pain; marble-sized nodule, with several pea-sized nodules in skin of chest wall under axilla. The arm had been swollen nearly twice its normal size since the operation. Aug. 18, 1910, to Sept. 30, 1910, the patient received 5 c.c. doses of "P" fluid twice a week, with no increase in size of nodules during this time and a noticeable decrease in the purplish-red color of skin over nodules. The swelling of the arm was controlled by massage. This case was taken early and ought to have been a favorable one for retardation. Up to Nov. 15, 1910, the disease seemed to be held completely at a standstill, but afterward there was more pain and a very slight increase in the size of the nodules. The general health, however, remained excellent.

Case 45.—Mr. H. T., aged 65, Dec. 29, 1909, had an eyebrow excised with a plastic operation for epithelioma. There was recurrence in right side of neck in May, 1910. At time of admission patient had small, hard glands under right jaw and a mass the size of a pigeon's egg under the symphysis of the jaw. The breath was foul. There was no involvement of mouth. September 20 and 27, "L" fluid was administered, with some softening in mass. Fluids were continued to Oct. 25, 1910, when patient evidently had an infection of the diseased area, with swelling, pain and redness. This subsided under poultices, and patient was admitted to hospital in November and the greater part of the mass removed. He made a good recovery. Patient remained in this condition for one month, with no increase in size of remaining nodule. Jan. 15, 1911, there was a second flare-up of the process and rapid increase in size of mass, with breaking down in several places.

This was another jaw case in which the process seemed to have been checked for a time, but which later developed with lightning-like rapidity. This series makes one doubt the beneficial influence of the ascitic fluids in jaw cases. They even seem to be harmful in some cases.

Definite results witnessed in this series of cases are as follows:

In five cases there was a decrease in, or absolute abolition of, the pain previously complained of. These were cases in which maximum doses were given (Cases 19, 22, 33, 40, 43).

In three cases there was a decided increase in the discharge from an ulcerated surface and a breaking down of cancerous tissue, considerable portions of which sloughed away entirely—enough to cause moderate hemorrhage. In no case was a fatal or even dangerous hemorrhage produced. Moderate increase in the discharge from an ulcerated or broken-down surface has been noticed in practically every patient treated. This in some cases was only temporary, but was followed later by noticeable cleaning up in the ulcer and more healthy granulations.

Cessation of bleeding in several cases of uterine cancer was seen, especially in Cases 16 and 19.

Increase in pain was experienced in Cases 12 and 5, the latter patient, who had been having very large doses of x-ray previous to injection, had excessive pain even with very small doses of the fluid. In Case 37, however, the patient also had large doses of x-ray with his treatment, but had no increase in pain.

There was apparent retardation of the growth in eight cases for periods of two to five months, and in three others for a period of over one month. These tumors were growing very rapidly when started on the serum, and, when compared with other cases in this series, as well as in the control series, it seems justifiable to state that they have actually been retarded. These are Cases 14, 8, 9, 12, 4, 6, 13, 22, 26, 27, 31.

Physical as well as psychic effects of this treatment are often marked. Twelve patients have remained in excellent general physical condition, gaining strength and weight in spite of a slowly growing process, and this has been seemingly due to the stimulating effect of the fluid. This fact may be of some importance in relation to Leary's treatment of marasmic infants with ascitic fluid.[4]

On the other hand, in no case was there actual shrinking in the size of the tumor, and from the rapid increase in the size in two cases (3 and 12), there seems to have been a decided increase in the rate of growth of the tumor; due apparently to the use of the fluid.

There was no constant effect on so-called metastatic rheumatic pains.

In no instance was any marked harm done. One dose of a fluid, which "went septic," previous to being administered to several patients, caused marked constitutional symptoms which, however, passed off in twenty-four to forty-eight hours and left no ill effects so far as could be observed, the reaction being similar to that experienced with Coley serum.

The number of fluids available from resistant cases has not been large so that it cannot be positively stated that they always have a more specific action on the cancer than the fluids from less resistant cases, but it has been noted that local and constitutional reaction has occurred more often from the use of the fluids from resistant cases, and from this we are led to believe that their action is more specific, and hence beneficial.

CONCLUSIONS

A trial of seven months' duration has now been made with a series of forty-five cases, comprising variety enough both in the fluids used and in the type of cancer treated to warrant the following statements in conclusion, based on a careful analysis of the results in this series.

1. The various transudates and exudates of the body, cancerous and non-cancerous, have no effect in retarding the growth of cancer in mice.
2. The use of cancerous ascitic fluid from patients in the active or even moderately resistant stages of the disease has no permanent effect in preventing or checking the growths of cancer, or permanently benefiting the cancer patient.
3. The other non-cancerous body fluids are even more inert.

---

[4] Boston Med. and Surg. Jour., Aug. 18, 1910, p. 283.

4. Temporary beneficial effects may be noticed for periods of one to five months, but the course of the disease is in no way permanently retarded.

5. Temporary relief from pain, especially in uterine cases, and in other cases in which large doses can be given, and retardation of the growth for periods varying from one to five months, may be expected in a small per cent. of the cases.

6. Noticeable benefit in the general physical condition has resulted in one patient with cancer of the ovary by the injection of her own fluid.

APPENDIX

Since the completion of this report on the first forty-five cases, Oct. 1, 1910, twenty additional patients have been treated, with practically the same results as in the reported cases, which have confirmed our stated conclusions.

The information obtained from these twenty additional cases, and the more complete following up of the forty-five original cases, emphasized the following points:

1. Great symptomatic relief can be obtained in a good percentage of the patients treated, evidenced by relief from pain and improvement in nutrition and general physical condition.
2. Retardation is noticeable and prolonged from one to six months in many cases.
3. Ascitic fluids are liable to hasten the process in practically all mouth and jaw cases.
4. This work, together with the use of the *x*-ray in other cases, and curetting and skin-grafting sluggish epitheliomatous ulcers, has impressed me with the fact that much can be done for the relief of the seemingly hopeless inoperable cancer patient. While cures and benefit cannot be expected in every case, in spite of the fact that no cures have been accomplished, the work has emphasized the fact that much symptomatic relief can be given to suitable individual cases.

527 Beacon Street.

CHEMICAL DERMATITIS FROM INCOMPATIBLE EXTERNAL APPLICATIONS

A. M. MENDENHALL, M.D.
IOWA CITY, IOWA

It is a well-known fact that dermatitis is frequently caused by internal medication. With somewhat less frequency do we see a case of dermatitis caused by a combination of internal medication with a wrongly chosen external application—as for example, iodids internally and calomel dusting powders externally. Still more rarely do we see a case of dermatitis caused by chemically incompatible drugs used externally; and it is for this reason that I consider the following case of sufficient interest to be reported:

History.—A patient, male, came to me suffering from a typical case of impetigo contagiosa. There were eight or ten lesions irregularly distributed over an area about 8 cm. in diameter in the left anterior cervical region. Ammoniated mercury ointment was ordered.

Dermatitis.—The patient returned the following day to say that shortly after the first application of the ointment the area began to burn and sting severely. For several hours he underwent a great deal of discomfort. On examination it was found that a very large area, probably from 15 to 20 cm. in diameter, was highly inflamed. It was of a diffuse bright red color, with several small blisters and larger blebs which contained a thin seropurulent exudate. Some of the larger blebs were from 1 to 2 cm. in diameter. Careful inquiry proved that no mistake had been made in the ointment used. Inquiry was then made as to whether the patient was taking iodids. This inquiry was answered negatively, but brought out the fact that the so-called colorless tincture of iodin had been used externally.

This tincture of iodin had been prepared by adding to ordinary tincture of iodin enough sodium thiosulphate to displace the color. It should be remembered that such a pharmaceutical preparation would result in a mixture of sodium iodid and sodium tetrathionate, and that since it would no longer contain free iodin it should not be called "tincture of iodin" ($2Na_2S_2O_3.5H_2O+I_2=2NaI+Na_2S_4O_6\ 10H_2O$).

I attributed the condition to biniodid dermatitis. As a means of corroboration some of the "tincture of iodin" and the ointment were rubbed up together and the white ointment was at once converted into a pink or brick-red. Extraction of the oil by ether left a brick-red granular precipitate.

The reaction in and on the skin between the sodium iodid (NaI) of the mixture and the ammoniated mercury ($HgNH_2Cl$) of the ointment had evidently resulted in the production of biniodid of mercury (HgI_2), which, through its irritating influence, had produced a dermatitis.

A PECULIAR CAUSE OF INTESTINAL OBSTRUCTION

ISRAEL BROWN, M.D.
NORFOLK, VA.

Patient.—E. Z., a white man, aged 29, family history negative, was seen first by family physician September 8, suffering with pain in the abdomen, was given purgatives without any relief. Next day purgatives and enemas were given without any relief. In the afternoon, when I saw the patient, he had pain of an intense griping character and vomiting; he retained nothing by stomach; had no fever. The diagnosis was intestinal obstruction.

Operation.—When the abdomen was opened in the median line, free fluid was found in the abdominal cavity. In the ileum, about two feet from the ileocecal valve, two hard lumps, 2 inches apart, were found obstructing the lumen of the intestine. The intestines were incised, the foreign bodies removed, the intestine sutured, and the abdominal wound closed.

The patient made an uneventful recovery.

The foreign bodies consisted of unmasticated dried apples. The patient had been eating, the morning of his illness, apples dried in portions of halves and quarters, swallowing them without much mastication. The portions after entering the intestines continued to swell, as dried apples do, and obstructed the lumen of the intestine.

Therapeutics

GENERAL PROPHYLAXIS OF TYPHOID FEVER

In many particulars, no disease surpasses typhoid fever in its importance. It attacks, as a rule, healthy adults, causing a sickness that may last for weeks and even months, and may frequently end in death. It is one of the most preventable of all infectious diseases; it is, therefore, almost inexcusable that it is so widely prevalent.

It is now generally recognized that the essential agent in the causation of typhoid fever is the *Bacillus typhosus*. Since its discovery in the early '80s, and subsequent careful investigation by a number of students, our knowledge of the method of its transmission has been greatly increased. The bacillus has been found in the blood, in the feces, in the urine, and in the bile. It cannot always be discovered in the early days of the disease, but in the second or third week it can generally be detected. It may persist for years, even as many as twenty-five or fifty, after the patient has become convalescent. It may also exist in the body, and particularly in the feces and urine of individuals who have never themselves, so far as can be determined, suffered from an attack of the disease, but who have taken the infection into their bodies in some perhaps unexplained way. These individuals in whom the bacillus exists are known as "typhoid carriers," and those in whom the bacillus exists, but who have never suffered from an attack of the disease, are known as "contact carriers."

The problem in the prevention of typhoid fever is the destruction of the bacilli which are excreted by the patients suffering from the disease, or by the typhoid carriers. It might seem that this would be a simple task, and it has been claimed that typhoid fever might be stamped out in any country within a year, but such a very desirable and Utopian result seems very unlikely of accomplishment in our generation.

To consider first the measures which should be adopted in the case of the patient who is ill with typhoid fever: It is the duty of the physician to lay down such rules for the guidance of the patient and his treatment as will effectually prevent the dissemination of any of the morbific bacilli. The physician's first and most important duty is to make an early diagnosis of the disease. It has been too much the practice in past years for the physician to neglect this important part of his work. Patients have been treated for malaria, for simple continued fever, for bilious fever, and many other real or imaginary conditions who actually were suffering from typhoid fever. There is no excuse to-day, and there has not been much excuse within the last twenty or thirty years, for any physician to overlook the possibility of his patient having typhoid fever on the first day of his attendance. This does not mean that he must actually make a positive diagnosis of the disease at his first visit, but it does mean that he must be on the alert to consider the possibility that his patient may have typhoid fever; and if he does this he will save himself and the community a great deal of trouble.

While possibly the infection may be communicated by a person in the first few days of the disease, this is not nearly so probable as during the second and third weeks, when the danger is the greatest.

The bacilli are found most frequently and most abundantly in the feces. It has long been recognized that in them the chief danger of the transmission of the disease lies, and it has long been recognized that their effective disinfection is most important and most necessary. This the physician should insist on. There are various methods of doing this. The feces immediately on being passed should be covered with a 5 per cent. solution of phenol, and the hard masses should be broken up so that the disinfectant will thoroughly penetrate the fecal matter and come in contact with all microorganisms which may exist therein. Other disinfectants may be used, such as the chlorid of lime, corrosive sublimate, cresol, and the sulphate of iron. The utmost cleanliness should be used by the attendants in connection with the movements of the bowels. The skin surrounding the anus should be carefully washed with a disinfectant solution, and the cloths used for this purpose should be put in paper bags and subsequently burned. The attendant also should, after bathing the patient, always wash her hands in a disinfectant solution. In a similar manner the urine should be discharged into a vessel and mixed with a disinfectant solution.

The bacilli can sometimes be found in the sputum, and if the patient has any cough, the sputum should be collected on cloths and burned. Even if the patient has a dry cough, expectorating the so-called droplets from the mouth, pains should be taken to collect this on pieces of cloth which should be burned.

All bedding should be soaked in a disinfectant solution and boiled before being washed. The cups, glasses, dishes, knives, forks, spoons, and napkins used by the patient should also be disinfected before being washed.

During convalescence, the feces and the urine should be subjected at intervals to bacteriologic examination, to determine whether the bacilli are still present. It has been found that they may be absent at one time, and may reappear later, so that repeated examinations are necessary. The patient should be carefully isolated until repeated examinations have shown entire absence of bacilli, both from the feces and the urine. When these rules have been observed in the care of any patient suffering from typhoid, he, his friends, and the physician, will rest assured that there will be very little likelihood of his communicating the disease to anyone else directly or indirectly.

As has been stated, the disease may be carried directly from the patient suffering from the disease, or from a so-called bacillus-carrier. The bacilli may be received directly by a person who does not possess immunity to the disease by handling articles, such as clothing or utensils used in eating, which have been contaminated by fecal matter, urine, or sputum from a typhoid patient. A far more common mode of infection is indirect method, which embraces infection through water and through various food supplies, especially milk and oysters. Many epidemics have been due to the infection of a water-supply from patients suffering with typhoid. This may occur to a limited water-supply, such as that furnished from a well or spring to a single family or to a few families, or to the water-supply of a large city. It was recognized many decades ago that a well, spring, or water-supply might be infected by improper disposition of the fecal discharges of a patient suffering from typhoid. Before disinfection was generally recommended and occasionally done, it was a common practice to throw the discharges from the bowels onto the ground in any convenient place, or into a so-called privy. If this happened to be in winter, when the ice and snow melted, or in any season of the year, when the rain fell the bacilli contained in the discharges were washed away through the ground, and if a spring or well or brook happened to be in the way of this current of flowing water, it was sure to be contaminated with the bacilli, and the people who drank of the water were very likely to become infected with the disease. With the more general spread of the knowledge of the nature of the disease and the manner of its introduction into the system, this method of transmission is becoming less frequent and less important.

Another important agent, and perhaps at the present time the most important of all, is the milk supply. It has been determined that typhoid bacilli multiply in milk, and this is true of very few other media. The milk may be contaminated in various ways, either directly from patients suffering from the disease, or from a bacillus-carrier. The infection may occur from handling the milk with infected hands, or from the use of infected water in washing the cans and bottles in which the milk is carried. This is to-day perhaps the most common, and yet the most elusive method of transmission.

Shellfish in general are said to be common media for the transmission of typhoid, but the oyster is the chief agent in this communication. This happens in the following manner: The oysters are taken from deep water and placed in shallow, fresh water in order that they may absorb the fresh water and, as the expression is, become fattened. This shallow water is very likely to become infected by sewage from surrounding houses, and if there happens to be a case of typhoid fever in a house, the sewage of which drains into the bed where the oysters are fattened, the oysters are likely to absorb the bacilli and carry them to anyone who eats the oysters, unless they have been thoroughly cooked.

TYPHOID BACILLUS-CARRIERS

One of the most interesting, and perhaps the most important, problem connected with the prophylaxis of typhoid fever which has attracted study and discussion during the last dozen years is that of the typhoid bacillus-carrier. It is only within comparatively recent years that it was discovered that a not inconsiderable number of cases of typhoid fever, whose origin had been inexplicable by the ordinary known methods of contagion, were due to infection from persons whose excretions contained the typhoid bacilli, although they had not recently themselves been ill with the disease.

These bacillus-carriers were found to be divided into two classes: one class embracing those who were known to have had well-marked attacks of typhoid fever; the other, those who had not suffered an attack of typhoid, so far, at least, as it was possible to learn from a study of their pathologic history. These latter individuals are believed to become infected with the bacilli by contact with some individual suffering from typhoid fever, but through the possession of some immunity they do not suffer the ordinary febrile attack of the disease, but the bacilli remain within their bodies and undergo multiplication and subsequently are excreted.

Under another form of classification these bacillus-carriers are distinguished as: (1) precocious carriers, which includes persons who have been recently infected with the disease but have not yet shown symptoms of it, although they may later do so; (2) the convalescent, temporary or transitory carriers who have passed through the disease and are convalescent from it, but whose excretions still contain the bacilli; (3) the chronic carriers, those who after an interval of three or four months have not ceased to present the bacilli in their excretions.

It is generally recognized that typhoid bacilli occur in the blood in a large majority of patients suffering from typhoid fever. In the feces, they are found most frequently about the third week of the disease. Various observers have found them in from 33 to 100 per cent. of cases in the third and fourth week of the disease. They are less commonly found in the urine, in ordinary cases, but it is generally agreed that they are found there in from 20 to 25 per cent. of typhoid patients. Some observers believe that in all cases in which the bacilli are found in the urine, there will also be found a slight trace of albumin. They may appear in the urine early in the disease, and in the majority of cases disappear in from three to thirty days, but in exceptional cases they may persist much longer. These facts render it important, from the standpoint of the sanitarian, to observe the cases of typhoid fever during convalescence much more thoroughly than has hitherto been done. When it is considered that these bacillus-carriers may continue to excrete bacilli for from one to fifty years after the original attack of the disease or the original infection, the immense importance of preventing their existence is easily recognized.

The natural corollary of these observations is that the health authorities in every city should conduct systematic observations of the urine and feces of every typhoid fever patient until repeated examinations on different days show that both these excretions are free from typhoid bacilli. It has been suggested that when the typhoid bacillus-carriers have been entirely eliminated that very much will have been done to entirely abolish typhoid fever.

When it has been determined that a certain individual is a typhoid carrier, the next problem is how to stop his elimination of typhoid bacilli. This is a problem which is both important and difficult. Where the bacilli are eliminated with the feces, it must be taken into account that the gall-bladder is a very important focus for the development of the bacilli. This is often associated with inflammation of the gall-bladder and with the development of biliary calculi. In fact, long before the existence of bacillus carriers was even suspected, it had been noted that people who had had typhoid fever were especially likely to suffer from inflammation of the gall-bladder and from biliary calculi.

The attempt has been made to destroy the bacilli in the gall-bladder and intestines by the administration of various drugs, among which may be mentioned hexamethylenamin (urotropin), salol, beta-naphthol, oil of turpentine, sodium salicylate, chloroform, calomel, and bile and its salt. All of these drugs, however, have but a temporary effect. The most useful are hexamethylenamin, sodium salicylate, and salol. Even the *x*-ray has been tried, but seems to be of little value.

When the bacilli are found in the urine, hexamethylenamin has been tried, and while it does decrease the number of bacilli eliminated during its administration, they often reappear when the use of the drug is discontinued.

When drugs fail, the vaccines, preferably the autogenous vaccines, have been used with apparent benefit in several cases. The usual dose is from 40,000,000 to 1,000,000,000, repeated several times. This treatment with vaccines is the more efficient the earlier during convalescence it is commenced.

The carrier himself usually suffers little inconvenience from the presence of the bacillus within his body. In some cases there may be gall-bladder symptoms, due to inflammation of the gall-bladder, or to the formation and presence of calculi. Occasionally headaches are complained of. Sometimes intestinal disturbances are noted, especially in the spring, summer, or late autumn. When the carrier is aware of his condition, and of the efforts which are taken to cure him of it, if of a nervous temperament, he may develop a form of neurosis. Sometimes the carrier may succumb to a general infection by his own bacilli causing auto-infection.

Neurasthenia an Insanity.—In pure neurasthenia there is no disturbance of the general relationship of the individual to his environment, no disorder of conduct, and therefore no insanity. It is unfortunate that the term "neurasthenic insanity" should have been applied to patients suffering from this condition in whom, while there is admittedly no insanity, the mental symptoms are exceedingly prominent. It is totally erroneous to speak of insanity, however we may qualify it, in regard to persons who are not insane, and a better term for these conditions of neurasthenia in which the symptoms are largely mental would be "psychasthenia gravis."—A. F. Tredgold, in the *Practitioner.*

IMPURE AIR AND MEDICINE

Impure air has long been considered the direct cause of many diseases which modern medicine can no longer explain on that basis. Laymen still not infrequently ascribe such diseases as typhoid and diphtheria to "sewer-gas" contamination, and the very name of malaria bears testimony to the erroneous theory with regard to it formerly held by the medical profession. But there remains a large and important class of diseases, principally of the respiratory tract, in the production of which atmospheric impurities play no small part. So, for instance, workers in the dust-producing industries are notoriously liable to tuberculosis, to say nothing of the added danger in the case of those dusts that in themselves are poisonous.

The vast expansion of our modern industrial centers, with the aggregation of large numbers of smoke- and soot-producing furnaces, has opened a new phase of the subject, and one whose exact significance is still a matter of dispute. The ultimately injurious action of the constant inhalation of smoke and carbon particles can almost be assumed as self-evident; but that it has effects of any great seriousness cannot be regarded as proved. In a long series of articles Ascher[1] has sought to demonstrate, by both statistical and experimental evidence, the directly injurious action of the "smoke plague" in causing death from acute inflammatory diseases of the respiratory tract.

On the other hand, Gebecke[2] in a recent article, disputes Ascher's findings, both experimental and statistical. Inasmuch as his statistical data are for the most part derived from the same sources as those of Ascher, the ultimate result seems merely to demonstrate anew the proverbial fallaciousness of such evidence. But, nevertheless, Gebecke's article serves to indicate that our modern smoke evil has not the pronouncedly harmful effect on the mortality rate that one might be inclined to assume. In regard to such diseases as may be considered as directly air-borne, such as those produced by the poisonous dusts, or by inhalation of "infectious droplets," the situation is of course quite different. The recent rapid spread of the pneumonic form of plague in North China demonstrates strikingly the potentialities of direct respiratory infection; and occupational dust-poisoning, although far less wide-spread, has been considered of sufficient importance to justify legislative control in some parts of Europe at least. The means taken to combat the evil are as ingenious and as varied as are the different industries in which it occurs. Moistening of material, substitution of innocuous ingredients for the poisonous ones, and removal of dust at the point of origin, are all taken advantage of when possible. But there still remain several industries in which these procedures are inapplicable, and in the worst of these, as for example the alkali, chrome, and dry lead works, the German government prescribes the use of respirators. A comparative experimental study has been made of the different types of these by Schablowski;[3] and his results are of interest as revealing the inefficiency of many such devices. Twenty-six of a total of thirty-seven masks of different manufacture permitted the passage of 30 per cent. or more of dust, some allowing as much as 89 per cent. to pass through. Of the remaining eleven, five were variations of the same model, and two were respirators constructed experimentally by Kobrak.[4] These last consisted simply of a fine-mesh batiste, fastened in cowl fashion by means of constricting bands about the forehead and shoulders, with an aluminum frame to keep the gauze some distance from the mouth and nose. Such a mask, it was found, absolutely prevented the passage of infectious droplets forcibly expelled by sneezing from a distance of 30 to 40 centimeters. With dust it was not so effective, as 18 per cent. passed through. On the substitution of filter-cloth for the batiste, this was reduced to 11 per cent., but at the expense of some degree of the comfort with which it was borne. The best of the commercial masks, similarly equipped, was just about as effective.

The data cited here seem to point out in some measure the difficulties that lie in the way of adequate legislative control of occupational diseases. As Schablowski somewhat pessimistically states, the choice of respirator in any given case would depend on the chooser; if the employer chose, the cheapest would be selected; if the male laborer, the most comfortable; and the female laborer, the most becoming—no one apparently being greatly concerned with the practical efficiency of the device.

THE CHOLERA SITUATION

Official reports indicate that cholera has appeared in Hawaii, 35 cases and 26 deaths having occurred between February 25 and April 16, 1911. This close approach to the Pacific Coast and actual infection of the island territory gives cause for concern at this time, when the disease has apparently receded from European ports.

[2] Gebecke: Ztschr. f. Hyg. u. Infectionskrankh., 1911, lxviii, 105.

[3] Schablowski: Ztschr. f. Hyg. u. Infectionskrankh., 1911, lxviii, 169.

[4] Kobrak: Ztschr. f. Hyg. u. Infectionskrankh., 1911, lxviii, 157.

The present pandemic that has now threatened both our Atlantic and our Pacific coasts began in India in 1902, and in that year spread to China and the Philippine Islands. Since then the disease has gradually but steadily extended, both by caravan routes and by sea, until Persia, Arabia, Egypt, Syria, Palestine and Asia Minor were infected. Had the infection stopped there, American shipping would have been in no great danger, but outbreaks also subsequently occurred in Russia, a few cases were reported from Germany, and during the past fall and winter rather severe outbreaks have occurred in different parts of Italy and the Madeira Islands.

During the past year, cholera prevailed in serious form in Japan, which was an added menace to the west coast, and now that the disease has reached Hawaii, the danger to the United States is more direct and threatening than at any time since 1892.

That there has been real danger of the introduction of cholera during the past few months is shown by the fact that cases were discovered among arriving aliens at the ports of New York and Quebec. The fact that Italy was declared free from cholera Jan. 31, 1911, and Funchal on February 24, is, on the other hand, reassuring, but the knowledge of the liability of recurrence of the disease in previously infected localities must be borne in mind.

It is altogether probable that the disease will recur in some parts of Europe during the coming summer, and render necessary close quarantine supervision over transoceanic shipping. During the recent past this supervision has consisted in the sanitary inspection of ships and passengers at both foreign and domestic ports, close medical inspection of aliens, and the notification of state and local health authorities regarding the destination in the United States of all arriving aliens.

Such precautions would seem to furnish more than adequate protection; yet, owing to the fact that the infection of cholera may be carried by healthy individuals showing no signs of the disease, it would be possible for a bacillus-carrier to enter the United States without detection, and the nearer the approach of cholera to our shores, the greater is this danger. The present situation, therefore, demands that federal authorities shall be provided with all adequate facilities to prevent the introduction of the disease and its spread, should it unfortunately gain entrance; and all health officers should be especially alert and look with suspicion on any intestinal disturbance, particularly in individuals recently arrived, or associated in any way with newcomers.

Neurasthenia and Movable Kidney.—Neurasthenia is an exceedingly common symptom of movable kidney. To those well acquainted with the anatomy of the kidney and the difficulty with which the organ is displaced from its position surgically, the idea that neurasthenia can cause movable kidney appears absurd. Neurasthenia can no more cause movable kidney than it can dislocate a joint.—C. W. Suckling, in the *Practitioner.*

PRESIDENT TAFT'S MESSAGE TO PHYSICIANS

> President Taft was tendered one of the most extraordinary receptions and banquets, as well as a demonstration of popularity last night, that has marked his career as President of the United States, and in being the guest of honor of the Medical Club of Philadelphia . . . received fitting tribute for his humanitarian endeavors while secretary of war and as chief executive.

Thus is expressed the layman's view—that of the Philadelphia *Public Ledger*—of the splendid testimonial banquet and reception tendered by the physicians of Philadelphia, of Pennsylvania, and of the whole country —for the country as a whole was represented—to the President of the United States last week at Philadelphia. The officers and members of the Medical Club of Philadelphia are to be congratulated on the well-planned and dignified testimonial to the President of the United States in recognition of his services to sanitary science and as an appreciation of his aid in the advancement of public medicine.

No other president has been so honored by the medical profession; and no other president has so honored the physicians of the United States. But it must be said also that no other president has been brought into contact with physicians and their work in so many ways—has had such a practical knowledge of what medical science has done and is doing—for no other president has had the opportunities for personal observation of the results of scientific sanitation that President Taft had in the Philippines, in Cuba, in Porto Rico, in the Canal Zone and as Secretary of War. His address to the thousand physicians at the reception—and to the medical profession of the country, for he took pains to emphasize the fact that he had a message for the medical profession of the United States—was a gratifying appreciation of the economic and humanitarian benefits that have resulted from modern medicine. It was also an evidence that, for a layman, the speaker had an unusually wide knowledge of medical affairs and grasp of medical science and what it has accomplished.

As one listened, one could not help believing that, if President Taft could have his way about it, public health matters would be given greater recognition by the national government than they are now given, even to the extent of the creation of a department of public health, with a secretary in the cabinet. Of course he did not say so. He did not even hint at a department of public health, or intimate that he had ever heard of such a proposition; but others thought of it, and three speakers who followed him mentioned it aloud, and with emphasis. Not that there was any indication of a desire on the part of any one to make use of the opportunity to advance the idea of a department of public health or any other measure; on the contrary, the spirit that prompted the function and that prevailed throughout the evening was that of brotherly love and of respect for the President, who by word and deed, in the many responsible positions he has occupied, has shown a knowledge of medical science and an appreciation of its importance, from the economic as well as from the humanitarian aspect, as has no other public man. The medical profession feels more than ever assured that President Taft is in sympathy with the plans for increased federal activity for better public health.

Current Comment

LIFE-SAVING ABROAD AND LIFE-WASTING AT HOME

It is significant, and by no means gratifying to our national pride, that President Taft,[1] when desiring to demonstrate the value of modern sanitary methods, was forced to draw all his illustrations from our island and provincial possessions. Modern sanitary science has abolished yellow fever in Cuba, discovered the cause and largely controlled the ravages of hookworm anemia in Porto Rico, barred yellow fever and Chagres fever from the Canal Zone, isolated leprosy in Hawaii and the Philippines and aided in the investigation of beriberi. This work has practically revolutionized conditions in our tropical possessions and has enabled the President to say that "in the short twelve years that we have been responsible for the health of our people in the tropical climates, we have made more progress in the discovery of methods of prevention and cure of tropical diseases than all other countries have made in the past two centuries." Modern sanitary methods backed up by intelligent and authoritative administration have indeed worked wonders in the tropics; but what of our own country? Tuberculosis, typhoid, pneumonia and the appalling black plague of venereal infection still lay waste the land. They are tolerated chiefly because we are accustomed to their presence. If tuberculosis were a newly discovered tropical disease, if typhoid fever were limited to the tropics, how horrified would we be at their ravages and how warmly would we applaud any efforts of the national government to control them! But through long association, we have become tolerant of their presence and reconciled to their destructiveness. Yet modern sanitation, if permitted, can effect as marvelous changes here as in the Canal Zone or in Havana.

PUBLIC HYGIENE AND PRIVATE PRACTICE

In his response to the toast "The American Medical Association," Dr. Welch emphasized one fact thoroughly familiar to physicians but not yet appreciated by the public, which should be given the widest possible circulation. He said: "Public hygiene and preventive medicine have acquired an economic and social significance among the organized forces of civilization but little appreciated to-day by the general public or by legislators and administrative officers of government. They occupy a field quite apart from systems and schools of medical practice." The opponents of increased governmental activities for the conservation of life are apparently unable to discriminate between the practice of medicine by the individual physician and the application of demonstrated scientific facts in public hygiene. In no other way is it possible to account for the fact that efforts to increase the health functions of the federal government have been regarded as an invasion of the personal rights of the individual. He who cannot distinguish between the treatment of an individual typhoid fever patient by an individual physician, and the removal of the cause of typhoid fever through the purification of the water-supply of a community, is still in an elementary state of education. The treatment of the individual patient is not and should not be a matter of governmental concern. The correction of insanitary and unhygienic surroundings and conditions is of the highest importance to the modern state and is worthy of its utmost activities.

THE PRESIDENT VERSUS "LIFE"

In a former number[1] we quoted the profound and learned comments of *Life* regarding the use of typhoid vaccine in the army. In his address before the Philadelphia Medical Club, President Taft said on this point: "Now we have a division of 1,800 men in Texas and California. They have been there for two months living under canvas and in a country soaked with rain. . . . I need not recall the dreadful record of sickness from typhoid fever in the camps at Chickamauga. . . . Of the volunteer regiments mobilized during the Spanish-American war, 90 per cent. [about 16 per cent. of the men] became infected with typhoid fever within eight weeks after the date of mobilization. To-day, two months after mobilization with the modern health regulations and by the use of vaccine against typhoid, not one case of typhoid has appeared in the entire force, except that of one teamster who was not vaccinated." This seems to be a question of veracity between President Taft and *Life*.

HUMAN FALLIBILITY

To one who, from time to time, looks over the accident bulletin of the Interstate Commerce Commission, it is not a little discouraging to see the number of accidents that continue to occur in spite of the endeavor of railroad officials to prevent them. One safeguard sought for is to have more than one employee responsible for the carrying out of one particular order so that, if one man forgets or fails, the duty will be performed by another, or, at least, the error detected; and yet we find an engineer rushing past both torpedo and red lantern, a conductor and engineer both misreading an order, a telegraph operator making an assumption contrary to written orders in his hand—each an instance of human fallibility. Then the trains come together and lives and property are lost. The human mechanism often seems far more fallible than mechanical safety devices. One reason may be that we are not accustomed to investigate cause and effect so rigorously in the case of the human as in that of the inanimate machine. When disaster occurs from the wrong working of a steel and iron machine, people do not stop with saying "The machine was to blame"; those who pay the cost of the new one usually find out whether the old machine was made of poor material, constructed on wrong principles, worn out or inefficiently operated; and they endeavor to avoid that cause of failure for the future. When a wreck occurred through the failure of a telegrapher to transmit orders or of an engineer to read them, if we may judge by the reports of those acquainted with the circumstances, the tendency in the past too often has been to stop with "fixing the blame," without endeavoring systematically to go further and find out how such errors can be eliminated thereafter. A letter published in this issue indicates that the railroads of the country are awake to their responsibilities. This is gratifying and creditable. Our correspondent, however, seems to take the position often assumed, namely, that the road cannot justly be held responsible for accidents due to failure of employees to carry out orders. We believe that more exhaustive study of the problem will show that a public service corporation is as responsible for the quality of its employees as for that of its machinery; as responsible for their discipline as for the repair of its equipment. Since, no matter how much may be required of inanimate machines, the directing human element can never be wholly eliminated, we hope that systematic study of railroad accidents from the point of view of the circumstances which affect the working of the human mechanism will some day help to reduce the total as nearly as possible to the sum of the humanly unpreventable.

CHILD WELFARE EXHIBITS

In the education of the public in hygienic and health matters, the child welfare exhibits that have been held in a number of cities constitute an important agency. The exhibit recently held in New York City was a pronounced success, being attended by a large number of people. An exhibit is being held in Chicago (May 11-25) and great interest is being taken to make it a success by both the municipal health department and the various public welfare agencies. Among the features of the exhibit are demonstrations of the methods of care and feeding of infants, infant hygiene, illustrations of defective methods and their results, graphic representations of the high death-rate of infants from preventable causes, the causes and manner of preventing blindness in infants, the problems of fresh air and light, play and play-grounds, the effects of work and the hours of work on children, what municipalities and the various social welfare agencies are doing for the welfare of the children, and by charts, placards, figures, pictures, exhortations, demonstrations, etc., showing what may and should be done for the advancement of the welfare of the rising and the coming generations of children to make them healthy, strong and efficient citizens. As indicated by the success of the New York exhibit, the demonstration in Chicago should have valuable educational results.

SACCHARIN AN ADULTERANT

The referee board that was appointed to review some of the decisions of the Bureau of Chemistry has recently concluded its investigation regarding the use of saccharin in foodstuffs. Those of our readers—and they are many—who received with regret the board's decision regarding the use of benzoate of soda, will be pleased to learn of its decision in the case of saccharin. The board reports that "the continued use of saccharin for a long time in quantities over three-tenths of a gram per day is liable to impair digestion; and the addition of saccharin as a substitute for cane sugar or other forms of sugar reduces the food value of the sweetened product and hence lowers its quality." On the strength of these findings, the United States Department of Agriculture has declared that after July 1, 1911, saccharin-containing foods will be regarded as adulterated within the meaning of the Food and Drugs Act. As saccharin is several hundred times sweeter than sugar and by no means an expensive product, it has been used for years as a substitute for sugar by manufacturers who are more concerned with their dividends than with the quality of their products. Enormous quantities have been used as a sweetening agent in the inferior qualities of ginger ale and it has been used to some extent by the manufacturers of canned corn, peas, etc., to lend an artificial sweetness to these products. Fortunately, this form of fraud—for it is a form of fraud—will have to cease, so far as goods for interstate commerce are concerned, after the first of July of this year.

Medical News

ILLINOIS

Hospital Corner-Stone Laid.—The corner-stone of the Deaconess Home and Hospital of the Central Illinois Conference of the Methodist Episcopal Church, Peoria, was laid, with impressive ceremonies, May 3.

State Surgical Institute for Children.—Companion bills, providing for the establishment of a state surgical institute for children under 14 years of age and appropriating $60,000 for buildings and $15,000 for furnishing, were passed by the House of Representatives, April 26, without a dissenting vote. The establishment of the institute is dependent on the donation of 160 acres of suitable ground for a site.

Optometry Bill Defeated in Senate.—The State Board of Health announces that Senate Bill No. 140 to regulate the practice of optometry in the State of Illinois was defeated in the senate, May 3, by a vote of 14 to 10. Eighteen more senators were present but did not vote. To pass a bill, twenty-six votes are required. This action is said to kill the house bill which is still in the subcommittee of the judiciary committee of the House of Representatives.

Personal.—Dr. Arthur F. Wilhelmy, Decatur, has been detailed for duty at the maneuvers, San Antonio, Tex.——Dr. and Mrs. Hugh M. Orr, LaSalle, sailed for Europe, May 3.——Dr. Charles W. Hall has been appointed physician for Kewanee Township.——Dr. James D. Harlan has been made mayor of Fairfield.——Dr. Wiliam G. Alexander has been elected president and Dr. William C. Danforth secretary of the Evanston Tuberculosis Institute.——Dr. Theodore F. Gerould, Centralia, has been appointed diphtheria coroner of Marion County.

District Society Meeting.—The District Medical Society of Central Illinois held its thirty-seventh annual meeting in Pana, April 25, and elected the following officers: President, Dr. Melvin P. Parrish, Decatur; vice-presidents, Drs. John H. Miller, Pana, and Edgar B. Kerr, Westervelt, and treasurer, Dr. John N. Nelms, Taylorville.——The annual meeting of the Rock Island Medical Society was held in Rock Island, April 11. The following officers were elected: President, Dr. Warner L. Eddy, Milan; vice-presidents, Drs. Evlan Sargent, Moline, and William D. Snively, Rock Island; secretary, Dr. Albert Nicholas Mueller, Rock Island (reelected); treasurer, Dr. Arthur Thomas Leipold, Moline (reelected); delegate to the state society, Dr. Henry S. Bennett, Moline, and alternate, Dr. Joseph R. Hollowbush, Rock Island.

Approves Endeavor to Raise Standard.—Henderson County Medical Society, at its last meeting held in Stronghurst, adopted resolutions setting forth the existence of a number of unnecessary medical colleges from which great numbers of *incompetent or illiterate* physicians are graduating; that some of the best equipped medical colleges, owing to competition, are graduating improperly qualified physicians; that state boards of examiners have not proved themselves capable of neutralizing the lenient tendencies of certain medical colleges; that many teachers in medical schools reap undue advantage from their connection with such schools in the way of honors and fees; and that the *foregoing conditions* are disastrous to the country practitioner; and resolving that the management of the American Medical Association be thanked for the services already rendered in the way of elevating medical standards, and that it be requested to employ its utmost endeavors still further to raise the standards of medical education and of medical practice in the United States.

Chicago

Hospital Enlarges Site.—Provident Hospital has acquired property north of its present location as the result of a campaign which brought in seventy-eight contributions, ranging from $1.00 to $1,000 each.

Hurt in Auto Wreck.—Drs. James A. Jennings and H. E. Corley, while riding in their automobile across a grade crossing of the Chicago Terminal Railroad, May 4, were struck by a train and painfully injured.

Much Communicable Disease.—During the week ending May 6, twenty-six cases of diphtheria were received at the Contagious Disease Hospital. Twenty-eight patients were discharged, recovered, two died, and sixty-four patients still remain under treatment. The Isolation Hospital received seven cases of small-pox, all of unvaccinated individuals, discharged five patients, recovered; one patient died, and thirty-one remain under treatment.

Staff Returns to Hospital.—Drs. Alice Conklin, Henrietta M. Farquharson, Bertha Van Hoosen, Grace Campbell, Lois L. Wynekoop, Sara J. McCollum and Louise Acres, who were discharged from the staff of Mary Thompson Hospital on charges of alleged insubordination March 1, have been reinstated, and, beginning with May 9, the institution is operated under new management. The new plan provides that the Chicago Woman's Club will be represented on the board of control by eight of the twelve members.

MARYLAND

Personal.—Drs. Timothy Griffith and J. Marshall Price have been appointed members of the Board of Health of Frostburg.

Increased Accommodation at Sanatorium.—A contract has been entered into, that will provide accommodation for two hundred advanced tuberculosis patients at the State Tuberculosis Sanatorium.

County Society Election.—Montgomery County Medical Society held its annual meeting and election at the Chestnut Lodge Sanatorium. Dr. James Dudley Morgan, Chevy Chase, was elected president; Dr. Frederick N. Henderson, Rockville, vice-president; and Dr. John L. Lewis, Bethesda, secretary and treasurer. (reelected).

Hospital Transferred to Church Authorities.—The papers formally conveying the Maryland General Hospital to the Methodist Episcopal Church were signed April 27. The conveyance was made in return for the assumption by the church of the debt of $167,000 which rests on the institution. The relations of the faculty of Baltimore Medical College to the institution remain unchanged.

No Attempts to Violate Pure Food Law Discovered.—Dr. Charles Caspari, Jr., Pure Food and Drug Commissioner, says that not a single deliberate attempt to violate or evade the state pure food law has, as yet, been discovered. In his opinion, the law has two defects which should be corrected: it grants permission to sell substandard goods, provided the formula is printed on the package, and it requires that every case be taken before the criminal court for settlement.

State Physicians' Meeting.—The one hundred and thirteenth annual meeting of the Medical and Chirurgical Faculty of Maryland was held in Baltimore, April 25-27, under the presidency of Dr. Franklin B. Smith, Frederick. The following officers were elected: President, Dr. Hugh H. Young, Baltimore; vice-presidents, Drs. J. L. Rieley, Pocomoke City, Daniel E. Stone, Mount Pleasant, and Joseph A. Chatard, Baltimore; secretary, Dr. John Ruhräh, Baltimore; treasurer, Dr. William S. Gardner, Baltimore; trustee, Dr. James W. Humrichouse, Hagerstown; councilors, Drs. Charles O'Donovan, Baltimore, Lewis C. Carrico, Bryantown, James E. Deets, Clarksburg, and Harry B. Gantt, Millersville; delegate to the American Medical Association, Dr. G. Lane Taneyhill, Baltimore; alternate, Dr. James J. Carroll; and members of the State Board of Medical Examiners, Drs. Lewis A. Griffith, Upper Marlboro, and James A. Stevens, Easton.

Baltimore

Faculty Appointments.—The following are recent appointments to the faculty of the College of Physicians and Surgeons: Dr. Charles E. Simon, professor of clinical pathology and experimental medicine, with Drs. G. Howard White and W. Milton Lewis as assistants, and Dr. Henry L. Whittle lecturer on physiologic chemistry.

Personal.—Dr. William Simon, the autochromatic photographer, is confined to his home with a slight attack of typhoid fever.——Dr. Lewellys F. Barker, who was operated on, April 10, for appendicitis and gall-stones, left the hospital, May 3.——The appointment of Dr. James M. H. Rowland to the Baltimore School Board has been confirmed by the city council.——Dr. Norman F. Hill underwent operation at Mercy Hospital recently, and is reported to be in serious condition.——Dr. Joseph C. Benzinger fell recently, breaking his arm.

Commencement at University.—At the approaching commencement of the University of Maryland, the address to the graduates will be delivered by Dr. Harvey W. Wiley of the Department of Agriculture, Washington, D. C. The honorary degree of LL.D. will be conferred on Christopher Johnston, M.D., A.M., Ph.D., professor of oriental history and archeology in Johns Hopkins University, who is a son of the late Dr. Christopher Johnston, for many years a leader in the profession of the state, and professor of surgery in the University of Maryland.

Favor Tropical Disease Congress at Baltimore.—The medical faculty of the University of Maryland has declared in favor of holding the Congress on Tropical Diseases, proposed at the recent meeting of the Medical and Chirurgical Faculty of Maryland, in Baltimore, as a recognition of the part played by the medical profession at the opening of the Panama Canal. It is pointed out that Drs. James Carroll, Walter Reed and Jesse W. Lazear received their training and inspiration in Johns Hopkins Hospital and the University of Maryland. The proposal is said to be meeting with general approval.

MASSACHUSETTS

Transfer of Nursery.—By a recent decision of the supreme court, the property of the Boston Day Nursery has been turned over to the dispensary in ratification of an arrangement entered into by mutual consent of both corporations, and actually in effect since last October. The dispensary is maintaining a hospital of sixteen beds for infants and children.

Bequests.—Under the terms of the will of the late Harriet E. Goodnow, Sterling, $5,000 is bequeathed to the Massachusetts General Hospital, $5,000 to the New England Hospital for Women and Children, and $5,000 to St. Margaret's Hospital; with the proviso that the money be used in each instance for the endowment of Waite memorial beds.

Hospital Notes.—The new St. Margaret's Hospital, Dorchester, Boston, was opened for public inspection, May 5. The building is situated on a high elevation and contains thirty-three private rooms. The hospital is an open-staff institution. ——On April 26, Dr. Caroline Hastings turned the first spadeful of earth for the foundation of the hospital, home and training school of the New England Moral Reform Society, on the old Fisher estate, Jamaica Plain.

Personal.—Dr. Henry J. Barnes, professor of hygiene in Tufts Medical School, Boston, announces that he will sever his connection with the school at the close of the present year.——Dr. Moses Greeley Parker, Lowell, was elected president-general of the Sons of the American Revolution, May 3.——Dr. and Mrs. John Bergeson, Boston, sailed for Europe, April 19. ——Dr. and Mrs. Martin T. Field, Salem, have gone abroad. ——Dr. Francis A. Bragg, Foxboro, has been reappointed medical examiner for Norfolk County.——Clement F. Coogan, Pittsfield, has been made a member of the State Board of Health vice James W. Hull, deceased.

MICHIGAN

Small-Pox in Hospital.—Small-pox which developed in the Homeopathic Hospital, Ann Arbor, April 22, was positively diagnosed as such, April 24. There were five cases and the patients have been quarantined on an upper floor of the institution.

Antituberculosis Association Formed.—At a meeting, held in Blissfield, April 18, at which Dr. Alfred S. Warthin, Ann Arbor, secretary of the State Society for the Prevention of

Tuberculosis, delivered an address, an antituberculosis society was organized and Dr. Rosingrave M. Eccles, Blissfield, was made chairman of the organization committee.

Personal.—Dr. James H. Bogan, Mackinac, while splitting wood a few days ago, cut off his left forefinger with an axe. ——Dr. Paul C. Dulitz, Detroit, has been elected president of the poor commission of Wayne County, and Dr. Otto Scherer, vice-president.——Dr. William Acker has been appointed city physician of Monroe.——Dr. Isaac W. Houston has been elected health officer of Marshall.——Dr. Clarence Young has been reelected mayor of Allegan.——The governor has sent to the senate the nomination of Prof. Robert L. Dixon to succeed Dr. Frank W. Shumway, Lansing, as secretary of the State Board of Health.——Dr. Henry A. Newkirk has resigned as health officer of Iron Mountain.——Dr. Charles N. Bottum, Birch, has been appointed physician of the Morgan Heights Sanitarium, Marquette.——Dr. James E. Mead, Detroit, major M. C., N. G. Mich., has been ordered for duty to the maneuver camp at San Antonio.

NEW JERSEY

Personal.—Dr. Richard Cole Newton, Montclair, has been appointed a member of the State Board of Health.——Dr. William H. Kensinger, Camden; Frank J. Hughes, Union, and Elmer S. Loomis, Mercer, have been appointed members of the State Tuberculosis Commission.——The residence of Dr. Robert H. P. Ellis, Paterson, was damaged to the extent of about $14,000 by fire and water, April 19.——Drs. William Franklin Faison, Louis Franklin, Oliver R. Blanchard, Edward Leonard Bull and William Phyle, all of Jersey City, will open a sanitarium on Fairmount Avenue in the Bergen section.

Health Officers' Association Organize.—At the meeting of the executive officers of the Board of Health of New Jersey, held at Newark, April 17, a permanent organization, known as the Health Officers' Association of New Jersey, was formed, with the objects of advance of knowledge relating to public health and sanitation and the encouragement of social intercourse among health board officials. C. H. Wells, Montclair, was elected president; John O'Brien, Jr., Plainfield, vice-president, and J. Scott MacNutt, Orange, secretary and treasurer. An executive committee was elected and the officers of this committee were instructed to draw up a constitution and by-laws to be presented at a meeting to be held May 17. All health officers allowed state board of health licenses are eligible for membership and, doubtless, this privilege will be extended to other health board officials and employees and members of local boards of health.

NEW YORK

Site for Tuberculosis Hospital.—An option has been given to the special supervisors' committee of Broome County on a tuberculosis hospital on the property owned by Mrs. W. B. Cleves, on the summit of Mount Prospect, near Binghamton, for $15,000. The building has been used for twelve years as a summer hotel and can, it is said, be utilized for a tuberculosis hospital with little remodeling.

Health Board Prohibits Exposure of Food.—Commissioner Lederle believes that the exposure of food to the dust and dirt of the public streets is a measure to health and has directed inspectors of the department to enforce strictly the sanitary code relating to the conditions under which food products may be sold when exposed outside of stores. The police department has been called on to assist in this work.

Hospital Notes.—Rockaway Beach has just opened its first hospital. It is a brick structure, built at a cost of $100,000, which was raised by popular subscription.——Mrs. O. H. P. Belmont and others who founded the Hempstead Hospital, Mineola, L. I., are said to be dissatisfied with the management of this institution. Recent action by the directors aims to do away with the hospital and to sell the property to Nassau County for an almshouse.

Antisyringe Bill Passes.—The assembly has passed the Boylan bill making it unlawful to sell at retail or give away hypodermic syringes or needles, unless the purchaser has a written order from a duly licensed physician or veterinarian. When syringes are sold to persons with orders the dealer is to enter the date of the sale and the name and address of the purchaser in a book kept for that purpose. The object of the bill is to reduce the rapidly growing drug habit.

Personal.—Dr. Robert E. Doran, Albany, has been appointed superintendent of the Long Island State Hospital, Flatbush, and Dr. Edward P. Case, Patchogue; has been appointed missionary of the American Board of Commissioners of Foreign Missions and, after six months' study in Paris, will go to Aintab, Turkey, and later to Erzeroum, Persia.——Dr. Eugene B. Horton has been appointed city bacteriologist of Niagara Falls, vice Dr. Harry C. Dumville.——Dr. G. H. A. Clowes, Buffalo, has gone abroad.——Dr. Charles H. Ludlum, Hempstead, is reported to be seriously ill with septicemia.

Bill Affecting Cold Storage.—The Senate Committee on Public Health has amended the Brennan bill and reported it favorably. The bill proposes to limit the period that foodstuffs could be kept in cold storage to six months, or if the State Commissioner of Health, or the State Commissioner of Agriculture permitted it, to one year. In its new form the period has been extended to ten months. Butter products are excepted and may be kept in cold storage for twelve months. The new bill requires the stamping of all foodstuffs received by cold storage warehouses with the date of receipt and gives the State Commissioner of Health authority to inspect and supervise all storage and refrigerating plants, to adopt reasonable rules for the protection of the consumer, and to designate persons to inspect warehouses.

New York City

New Hospital.—A new hospital in connection with the Ottilie Orphan Asylum in Jamaica, Queens Borough, has been dedicated.

Faculty Changes.—Dr. Henry Pike has been appointed assistant professor of physiology and will have charge of the undergraduate course at Columbia University.——Dr. Warfield C. Longcope, of the University of Pennsylvania, has been appointed assistant professor of medicine.

To Teach Office Hygiene.—The new Union Hospital, it is announced, will undertake to direct business and professional men, educators and ministers as to sanitary conditions under which they should work, and the length they and their employees should work each day and each year to make the most of their time, abilities and health.

Personal.—Dr. William L. Russell, Brooklyn, sailed for Europe April 29.——Fire in the residence of Dr. Joseph D. Nagel, New York City, April 30, caused damage amounting to more than $3,000.——Dr. Louise J. Bucholz, New York City, was given a surprise call April 22 by her friends of the Alumnæ Association of the New York Medical College and Hospital for Women, on the occasion of the twenty-fifth anniversary of her entrance into practice.

NORTH CAROLINA

District Society Meeting.—The fourth annual meeting of the Sixth District Medical Association was held in Durham under the presidency of Dr. William A. Graham of that city. The following officers were elected: President, Dr. John M. Manning, Durham; vice-president, Dr. Charles Henry Peete, Warrenton, and secretary, Dr. Charles Augustus Woodard, Durham.

Personal.—Drs. J. Howell Way, Waynesville, and William Oliver Spencer, Winston-Salem, have been reappointed members of the State Board of Health.——Dr. Bessie Puett, Dallas, has completed her term of service as assistant physician at the Williamsburg (Va.) State Hospital for the Insane and will enter practice at Dallas.——Major Eugene Beauharnis Glenn, Asheville, M.C., N.C.N.G., has resumed practice after absence of a month at the army maneuvers in Texas.

OHIO

Personal.—Drs. William T. Corlett and J. P. Sawyer, Cleveland, have returned from Europe.——Drs. Rodger Perkins and Howard D. Haskins, Cleveland, have been appointed to make an investigation as to the practicability and possibility of efficient chlorin disinfection of the city water-supply.——Dr. Lester E. Siemon, Cleveland, has been appointed a member of the State Board of Medical Registration and Examination. ——Dr. James A. Park, Columbus, fractured his right arm while cranking his automobile, April 20.——Dr. Edmund C. Brush, Zanesville, chief surgeon of the Ohio National Guard, has been retired with the rank of brigadier general.——Dr. Frank S. Thompson has been appointed a member of the Dayton Board of Health.

Tuberculosis News.—Dr. Henry Baldwin, superintendent of the Springfield Tuberculosis Hospital, has erected two tents adjoining the main building for incipient cases.——The directors of the infirmary for indigent tuberculosis patients of Stark County have suggested that a brick wing be added to the infirmary hospital at a cost of about $5,000.——At the first annual meeting of the joint board of commissioners in charge of the Kinnane Tuberculosis Hospital, it was reported that the average cost per patient had been $1.69 per day. There have been thirteen deaths since the hospital opened. Three patients left the hospital with the disease arrested, and at the end of the fiscal year eighteen patients were under treatment.——The new district tuberculosis hospital, Lima, has cost, for the site, $6,525, and for equipment and appurtenances $65,378.44. The hospital will now accommodate about thirty patients.——A resolution was introduced at the Cleveland Common Council, April 10, authorizing the expenditure of $238,329.12 for the erection of a tuberculosis sanatorium.

Cincinnati

Personal.—Dr. David I. Wolfstein, who was operated on recently for appendicitis in the Jewish hospital, has returned home.——Dr. Charles T. Pearce sailed for Europe, April 30. ——Dr. Otto Jeuttner suffered a stroke of paralysis, April 18, and is reported to be in serious condition.——Dr. James A. Rudolph has resigned from the health department to accept the position of milk and food inspector at Anderson, S. C.——Dr. Karl Zapp, at one time a prominent physician of Cleveland, is ill at the City Hospital with pernicious anemia.

Academy Censors Censure President.—At the meeting of the Cincinnati Academy of Medicine, April 17, the Milk Commission of the Academy, consisting of Drs. Albert Friedlander, Henry A. Woodward and Otto P. Geier, presented its fourth annual report and incorporated the following resolutions which were adopted:

> WHEREAS, Certain members of this Academy have, by innuendo and otherwise, cast reflection on the integrity of the members of the commission in special reference to the financial administration of their work; and
>
> WHEREAS, It has been suggested to the dairymen under the commission's supervision that they have been charged exorbitantly for such supervision; and
>
> WHEREAS, Such action directly impugns the honor of the members of the commission; now therefore,
>
> We, the members of this commission, do demand that these insinuations and the entire administration of the commission, from its inception to the present time, be searchingly investigated by the Board of Censors of the academy, who shall have power to employ an expert public accountant to assist them in their work. Furthermore:
>
> We ask that this report by the Board of Censors be submitted in writing and made the special order of business of the Academy of Medicine for 9 o'clock on Monday evening, May 1, 1911.

A motion prevailed that the academy reelect the commission in recognition of its faithful and beneficent labors. At the meeting of the academy May 1, the board of censors submitted an exhaustive report, which, on motion, was adopted. The report after reviewing the splendid work of the Milk Commission, described in detail their methods of investigation, including the investigation of all accounts by a certified public accountant, and their examination of all who were in any way connected with the affair. Not only was the Milk Commission exonerated from every charge made against them, but the censors adopted a vote of censure against Dr. William D. Haines, president of the Academy, Dr. Frank Lamb and Dr. George Strobach, editor of the *Cincinnati Lancet-Clinic*, on the ground that they had been guilty of unprofessional conduct in their methods of investigation of the work of the Milk Commission.

PENNSYLVANIA

One Board Medical Bill.—On May 4 the "One Board Medical Bill" was passed by the house on second reading, all proffered amendments being rejected.

Gift to Consumptive Home.—Through Dr. Herman L. Duhring, superintendent of the Protestant Episcopal City Missions, the treasury of the Home for Consumptives, Chestnut Hill, has received $2,000.

New Hospital.—The Armstrong County Physicians' Association has sold stock to the amount of $75,000 for the new hospital at Kittanning, which is to cost $100,000. The details for the purchase of the site on which the hospital is to be built have been completed.

Personal.—Dr. Robert Steele has been elected health officer and Dr. Oliver S. Weddell city physician of McKeesport.——Dr. Elmer G. Kriebel, Worcester, is ill with typhoid fever. ——At the reorganization meeting of the Board of Health of Reading, Dr. John N. Becker was elected president; Dr. Samuel L. Kurtz, a member of the committees on adulterations and poisons, and law and ordinance, and preventable diseases; Dr. William F. Marks, a member of the committees on drainage, sewerage and water supply, school hygiene, and registration and vital statistics; and Dr. Charles Roland, a member of the committee on registration and vital statistics.

Health Work in Pittsburg.—The annual report of the director of the department of health and charities, Pittsburg, mentions that the site for the tuberculosis hospital, for which $200,000 has been appropriated, will soon be selected, and that the plans will be ready shortly for the garbage incineration plant which is to cost $100,000. During the year there were 9,601 deaths, an increase of 2 per cent. over the preceding year, which is due, in great measure, to the great number of cases of infectious diseases, particularly measles. The medical inspectors made 80,000 inspections of school children during the year and the bureau of milk inspection, 17,797 inspections.

Philadelphia

Free Lunches for School Children.—The experiment begun in March by the lunch committee of the Home and School League, in order to prove the beneficial effects of the three-cent lunches (a warm meal at noon) on fifty children selected from the Woods School has been prolonged for an indefinite period.

For a Stricter Poison Law.—A conference at which Dr. Neff, Director of Public Health and Charities, and Dr. Christopher Koch of the State Pharmaceutical Board were present, was held at the private office of Coroner Ford, for the purpose of drafting a new and more stringent law governing the sale of cyanid of potassium and other deadly poisons and placing the bill before the legislature.

School for Consumptives.—Because of a disagreement with the superintendent of buildings of the board of education, the Phipps Institute has withdrawn its offer to erect an open-air school for incipient consumptives and generally weak children on the roof of the General McCall School, and instead will build its shelter and conduct its experimental classes on the roof of the College Settlement Building at Fifth and Christian Streets.

Dr. Oliver's Bequests.—The will of Dr. Charles A. Oliver gave his entire estate, valued at $15,000, to charity. The will directed that the estate be divided in three parts and the income be distributed: for the establishment of the Charles A. Oliver operating room at the Wills Eye Hospital for indigent blind and lame, to the University of Pennsylvania for an annual gold medal to the leading medical student in ophthalmology, and to the College of Physicians for the purchase of journals on ophthalmology. Dr. Oliver left his ophthalmologic library to Harvard University.

Plans to Reduce Infant Mortality.—Dr. Joseph S. Neff, Director of Public Health and Charities, has asked the mayor to send a special message to Councils urging that body to appropriate $5,000 to further the summer campaign against infant mortality. The plans for this work include the maintenance of the open-air hospitals on the Race and Chestnut street piers, keeping them open day and night, the establishment of a third recreation pier at Shackamaxon Street Wharf and the erection of a tent for open-air treatment of babies in Fairmount Park, provided the Park Commission will grant permission.

GENERAL NEWS

Orthopedists to Meet.—The twenty-fifth annual meeting of the American Orthopedic Association will be held in Cincinnati, May 15-17, under the presidency of Dr. Albert H. Freiberg. Headquarters will be in the Hotel Sinton. One of the features of the meeting is announced as the address by Dr. Edward H. Bradford, Boston, on "Currents and Counter-Currents in Medicine and Surgery."

Congress Committee on Organization.—The seventh meeting of the committee on organization of the International Congress on Hygiene and Demography was held in the Army Medical Museum, Washington, D. C., April 15, with Dr. Abraham Jacobi, New York City, in the chair. Dr. Joseph W. Schereschewsky, U. S. P. H. & M.-H. Service, was made director of the exhibition. An exhibition building is to be constructed on government land between the Washington monument and the Continental Memorial Hall for an exhibit in connection with the meeting of the International Red Cross in the spring of 1912, and the plan for this building, which has a floor space of 17,500 square feet, may be modified so as to accommodate the exhibit of the congress. The proposal will be investigated. The executive secretary was instructed to invite the executive officers of the life-insurance companies of the United States and Canada to contribute suitable exhibits of their mortality experience or medical statistics, with due regard to the elements of age, race, nativity, occupation, locality, anthropometry and other pertinent facts of medical or general interest.

PRESIDENT TAFT AND THE MEDICAL PROFESSION

Banquet and Reception to President Taft and Invited Guests

Given by the Medical Club of Philadelphia at the Bellevue-Stratford, May 4, 1911

The Medical Club of Philadelphia gave an elaborate banquet May 4, President Taft being the guest of honor. This delightful affair is commented on editorially in this issue. A report of the speeches follows, some of them being given in full.

The reception following the banquet was held in the greater ballroom of the hotel, beginning at 9:30 p. m.

DR. WILLIAM L. RODMAN, president of the club, presided and felicitously presented each speaker. In an appreciative tribute he introduced the President, saying, in part:

We could, sir, as loyal and patriotic Americans, spend more time than is allotted to us in reviewing your magnificent administration, its fruitful and beneficent results, and commend you for the unflinching courage and admirable patriotism shown in administering to the affairs of the nation. Twice in as many years have you called the national Congress to assemble in extraordinary session that it should do its plain duty by the people and enact legislation that it had failed to pass in ordinary session. It would be a superlative pleasure to review at length the many things which you have done for your fellow citizens at large, and which have caused you to be acclaimed by the foreign press as having done more to make possible international peace than any of your illustrious predecessors or contemporaries.

But we are only a lot of doctors, interested but untrained in matters of state, devoted to our profession and grateful to all who have lessened human suffering and have, by the opportunity offered by public station, inspired and enabled us to do better work in the line of our calling. No one, sir, has shown a greater appreciation of what American medicine has done, and can do, than yourself. Every official act as governor, secretary and President, affecting matters medical, has demonstrated your comprehensive and judicial grasp of the question under consideration.

The 8,000,000 inhabitants of the Philippines can never forget that you gave them educational, administrative and commercial advantages hitherto unknown to them; but, better than these, you, by a wise administration, gave them health by encouraging the study of tropical diseases, which has practically put an end to devastating epidemics of cholera and plague; and by segregating all lepers on the Island of Culion leprosy will eventually be stamped out. The hospitals of Manila are splendidly equipped, admired by all who visit them, and must ever remain as a monument to your constructive genius. In your brief administration in Cuba that troublous and turbulent people were quieted as if by the magician's wand. There you nationalized sanitation by causing to be created a department of health with representation in the cabinet. Formerly a perpetual menace to this country's health and commerce, Cuba is now visited by thousands as a winter health resort.

But greater than this was the work wrought on the Isthmus of Panama by the Medical Corps of the Army under your orders as secretary of war. This zone, for many years so inhospitable to human life that it was abandoned by the French, is now as healthful as Washington or Philadelphia. A work is there progressing, with a pace which almost staggers the imagination, that must, when finished, increase our importance as a world power, double the efficiency of our Navy and add countless millions to our commerce. Congress and the nation support you almost solidly in your insistence that so important, so costly, so strategic a position should be fortified. To do less would be to indulge in iridescent dreams that the day of universal peace—indeed, the millennium—were at hand.

But I should say that your greatest work, so far as our profession is concerned, was your urgent insistence in both of your annual messages to Congress that all of the governmental forces, outside of the Army and Navy, should be coordinated into an effective whole, and made into a Bureau or Department of Health. This the American medical profession has wanted, advised and worked for at least a quarter of a century; but you, sir, are the first president who has both recognized that it should be done and courageously insisted on it.

Much more could be said, but the proprieties of the occasion require that I should give way to one whom every body has come to hear. "Nothing can cover his high fame but Heaven." Therefore, gentlemen of the club, I wish to present you, your guests, and this magnificent audience to the President of the United States.

Address of President Taft

PRESIDENT TAFT arose amid cheers and, after the demonstration had subsided, said, in part: The "City of Brotherly Love" is one of the most important medical centers in this country. When, therefore, this Medical Club invited me to attend one of its meetings I gladly accepted, because it seemed to me that if I had any message to the medical men of the United States I could not find a more favorable place to deliver it than here.

Since 1898 and the Spanish war the people of the United States have been a colonizing and colony-holding people. We have become responsible for the welfare of Cuba, Porto Rico, the Isthmus of Panama and the Philippines. We have had under our care and guardianship the hygiene and the health of tropical peoples, and, while I should be the last one to minimize the importance and value of the benefits that we have conferred on the inhabitants of the tropics thus coming under our government of a political and economic and educational character, I do not hesitate to say that we have been most distinctly successful in the measures we have adopted, maintained and enforced for the improvement of the health and physical condition of these peoples in the torrid zone, over whom we have assumed guardianship.

It is not too much to say that the prevalence of yellow fever in Cuba and its constant recurrence as an epidemic in Havana and other cities of that island, so near to our own shores, threatening death to our own southern cities, was one of the chief causes, and, I may add, one of the real justifications for the popular feeling that led to the Spanish war. Hence it was that no sooner did we take Cuba, to bring it under our control, then the most strenuous efforts were directed toward cleaning it up as a pest-hole and changing its character as a neighbor dangerous to health.

The same task fell on us in assuming possession and control of Porto Rico, in undertaking the government and improving the conditions in the Philippines, and finally in the preparation of the Canal Zone for the construction of the canal. In the first three of these tasks of hygienic reform the control of governmental methods devolved in the first instance on the Army, because the early governments were all military governments. In consequence the health regeneration in these three colonies became the work of the Medical Corps of the Army; and so well was it performed that when the necessity for cleaning up the Canal Zone and making it healthful became apparent we took a member of the Army Medical Corps and put him in charge.

THE SANITARY REGENERATION OF CUBA AND PORTO RICO

It was while we were in Cuba that Walter Reed, an army doctor, investigated and verified the correctness of the theory announced some little time before, that the germ of yellow fever was conveyed from one human being to another by a certain species of mosquito. This discovery revolutionized the method of treating yellow fever, and it was made clear that the great effort and expenditure of money required to clean up Havana and the other infected towns, while useful in the prevention of other diseases, had little or no effect to prevent yellow fever. An entirely different course of procedure had to be followed. It was adopted in Havana and the other cities of Cuba, and was most successful; and one of those officers engaged in the work was Colonel Gorgas, of the Army Medical Corps.

Then we took over Porto Rico. We found that in that island the people were not suffering so much from yellow fever, but there was what was called "tropical anemia," and it was not long before an army doctor, Bailey K. Ashford, discovered that this was not the result of starvation and the absence of nutritious food, but was a disease due to the presence in the intestines of the so-called hookworm, and that it yielded to treatment, and that the many deaths and the general disability that the hookworm produced in the people of Porto Rico could be avoided in the future by comparatively simple and specific treatment. Half a million people have been the recipients of this treatment and have recovered, and a second campaign is now being planned of greater thoroughness, preparation and practice, which will doubtless rid the island of this disease.

THE TASK OF SANITATION IN THE PHILIPPINES

In the Philippines we did not encounter yellow fever, for that as yet had not reached the Pacific; but we found there, in glorious exuberance, cholera, bubonic plague, beriberi, malaria, small-pox, amebic dysentery and leprosy. By improving the water-supply and introducing mountain water into Manila, at a cost of $2,500,000, and by the introduction of artesian wells in many of the towns and villages of the interior, by regulations as to the food-supply, by a new sewage system in

Manila, costing $2,000,000, and by regulations securing the proper and safe disposal of sewage in the smaller towns and villages, and by the use of inoculation with cholera lymph, we have greatly reduced the number of victims from cholera in those islands. By a wholesale vaccination of all the inhabitants of the Philippines, carried on carefully and rigorously, we have practically stamped out small-pox of all kinds in the islands, in which the black small-pox of the most virulent type, flourished before our coming. By a crusade against rats and a cleaning up and destruction of the foci of the disease we have taken all the terrors in the Philippines out of bubonic plague. By careful attention to the destruction of the mosquito we have greatly moderated the injurious effects from malaria, and, while amebic dysentery continues to be a most dangerous and lingering form of disease in the Philippines in many cases, if treated in time it is subject to the control and cure of the remedies discovered and adopted there.

When we went to the Philippines lepers were at large. There were leper hospitals in Manila, in Cebu and in some other parts of the country, but the horrible and sickening character of them beggars description. We have segregated the lepers in all provinces in the islands to the number of 4,000, and have taken them to Culion, a beautiful island in the southern seas, have given them almost a self-governing colony and have made them so happy and comfortable that we have now no difficulty in inducing all persons afflicted with this disease to join the colony. The effect of this segregation has been to reduce the new cases annually of leprosy to 16 per cent. of what they were formerly.

One of the most obstinate and difficult diseases in the Philippines, and, indeed of the whole Orient, has been what is called "beriberi." For a long time the cause of it was beyond our discovery. But now it has been definitely traced to the use of polished rice as food. I need not go further than to say that 24 per cent. of the Japanese army were afflicted with beriberi during the Russian-Japanese war. The change of this food from polished to unpolished rice has practically stamped out the disease in the Philippines. This is a discovery since I left there, and I speak of it without practical knowledge, but only on report, but I know that the disease was under examination by the expert pathologists and investigators during my entire stay in the Philippines, and that the present discovery is only in keeping with the progress and success made in every other direction in the official inquiries made into the causes of tropical and Oriental diseases and their cure.

I may add that the investigations which have been made by our physicians into the character of the intestines of the native Filipinos indicate that those intestines are, if I may so say, a veritable "zoologic garden" of germs, microbes and bacilli that greatly enfeeble the race, and that by proper treatment might be eliminated, and the constitutions of the people at large greatly strengthened; and in the course of our stay in the Philippines I doubt not but that this method of strengthening the race will be pursued with greater and greater success.

SANITARY ENGINEERING IN THE CANAL ZONE

With all this experience, secured by our army doctors and those civilian physicians who followed them in Cuba, Porto Rico and the Philippines, we came to the problem of the construction of the Panama Canal, in a region as pest-ridden as any on the face of the earth. It is not too much to say that yellow fever and malignant malaria, known there as the "Chagres fever," contributed more than any other one cause to the failure of the French to build the canal; and when we went to the Zone to begin operations we found there lingering and ready to offer the same obstacles up to that time so fatal to success in this great work; but the Spanish war and the responsibilities it had thrust on us had given such light on the method of meeting and reducing these obstacles that we have finally swept them away. It took two years for us to make the necessary preparations before we could begin the work of excavation and construction. Those were a hard two years, with thoughtless critics demanding when the digging was to begin, criticizing every effort made and prophesying a dismal failure of our work. But we had selected as our medical officer a man who had acquired his knowledge in Havana and had practiced the new remedies there, and, with the resources of the government at his back, Colonel Gorgas changes a pest-ridden zone into a district as free from disease as any of the states of the south. He stamped out yellow fever so that for now more than four years there has not been a case on the Isthmus, and he reduced the malignancy and extent of malaria on the Isthmus to such a point that the percentage of deaths in the foreign population in the Zone is considerably less than in our large cities. He has made the Zone a pleasant place and a healthful place to live in. This great work of construction goes on without thought now of the dangers which made French success impossible.

Is not such a record one on which we can dwell with the utmost national pride? Does it not speak marvels for American courage, energy and scientific thoroughness, skill, research and power of original discovery? Other countries have been in the tropics for nearly two hundred years, and yet I do not think it an exaggeration to say that in the short twelve years that we have been responsible for the health of our peoples in tropical climates we have made more progress in the discovery of methods of prevention and cure for tropical diseases than all other countries have made in those two centuries.

OTHER SANITARY ACHIEVEMENTS

And now we have a division of 18,000 men in Texas and California. They have been there for two months living under canvas and in a country soaked with rain and deep with profanity-provoking mud. But so effective have been the regulative and preventive methods adopted to reduce sickness that the percentage of sick men is less than it was in the posts from which these men were mobilized. I need not recall the dreadful record of sickness from typhoid fever in the camps at Chickamauga and other camps established during the Spanish-American war. The percentage of typhoid cases was so high that it is hard to believe. Of 120,000 men there were twenty thousand cases, with a case mortality of 7 per cent. Of the volunteer regiments mobilized during the Spanish-American war 90 per cent. became infected with typhoid fever within eight weeks from the date of mobilization. To-day, two months after mobilization, with the modern health regulations and by the use of vaccination against typhoid, not one case of typhoid fever has appeared in the entire force, except that of one teamster, who was not vaccinated. It is hard to credit the accuracy of such a record. But, as I have it directly from the war office, I can assert it as one more instance of the marvelous efficacy of recent medical discoveries and practice.

When we consider how in times past the efficiency of an army has been reduced by large percentages through disease we can realize what an important part of the army the Medical Corps has become. But, without reference to war, when we consider the enormous advances made in the discovery of methods of preventing disease in the tropics, by members of the Medical Corps and under government auspices, and all within the last thirteen years, I think we may take pardonable pride in the record.

We expended many lives and much money in the Spanish war and in the discharge of the responsibilities that have followed that war. But they are as nothing compared with the benefits to the human race that have already accrued and will continue to accrue from the discoveries made under the conditions and necessities which the exigencies of that war and the governmental burdens following it presented.

I congratulate the Medical Corps of the Army, I congratulate the medical profession at large (for these discoveries were not all made by army doctors), that they have had the opportunity, and have seized it, to make such progress in relieving the suffering of the human race and in becoming, in so conspicuous a way, the benefactors of mankind.

Following his address President Taft was made the first honorary member of the Medical Club of Philadelphia, his certificate of membership being handed to him by Dr. Rodman.

Dr. Rodman, introducing Dr. S. Weir Mitchell, said: It is fitting that the President of the United States should be followed by the most distinguished and widely renowned physician in America, one who shares with Lord Lister of Great Britain, the mother country, the honor of being the world's two most famous medical men. We should felicitate ourselves, Mr. President, on the fact that the English-speaking peoples have given to science the greatest living physician and the greatest living surgeon. Not only does the gentleman I shall next present represent the noblest, the most cultured, the most ethical sentiments of American medicine, but he is your friend and former host, and the *beau idéal* of the Philadelphia profession. It gives me great pleasure to present—he needs no introduction—Philadelphia's most illustrious citizen, the eminent physician, the medical author, the historian and poet—"a man so various that he seems to be not one, but all, mankind's epitome"—S. Weir Mitchell.

The Debt of the Country to Physicians

DR. S. WEIR MITCHELL, Philadelphia, said, addressing President Taft: It is pleasant as citizens of the world to congratulate you and ourselves on your endeavor to establish arbitration and promote peace between the two great branches of the English-speaking race; nor could there be a more fitting occasion to remind you, and through you the people of this country, how deeply they are in debt to the American physician. For us this occasion is eloquent of opportunity. Your own profession of the law owes to you the illustration of judicial appointments where the only partiality shown was for ideal fitness and the possession of personal qualities such as your own life on the bench and at the bar has amply exemplified.

I said, sir, just now, that the country was in our debt. I would like to add that the country is of late more heavily than ever our debtor. We owe it to you, and I may add in part to your energetic predecessor, that you have given to the members of our profession who represent us in the ranks of the Army the first chance in the history of the world to prove what the intelligent despotism of educated discipline can enable the physician to effect for mankind. The chief of staff of the Army, General Leonard Wood, once—and he says "always"—a physician, with a group of young surgeons, swept the yellow-fever plague out of Cuba and freed the world from this terrible scourge; alas, at what sad cost! They cleared the island also of malaria and there and in the Philippines put an end to small-pox. You, sir, well know that it was Colonel Gorgas and his staff who have made so swiftly possible the gigantic engineering surgery which will have cleft the Isthmus of Panama from sea to sea. This was our opportunity; it was unique; and I beg to remind you, sir, and my fellow physicians, with pride, that our use of it was an unequalled display of hygienic competence.

You, sir, may not recall as I do what we did in the great war which welded the states into one. North and south the physicians remained an undivided guild in the service of humanity, while churches and the state were rent asunder. What our brothers in the south lost we do not know. We, ourselves, lost in battle 51 killed and 83 wounded, and 283 who died from disease. We have asked, sir, no reward; neither pensions, places, ambassadorships, nor even presidencies, have been for us. No memorial speaks of these great services; our dead are unrecorded in the annals of the war. The land is populous of statues of private and general; there remains for us the unrewarded consciousness of duty simply done in obedience to a creed old before Christ had spoken His great message to the world. You are, of course, aware that after a great victory general or admiral had sometimes been rewarded by the thanks of Congress. Is it too much to expect that when our flag leads a procession of the navies of the world through that great canal, Congress will commemorate the event by thanking, in the person of Colonel Gorgas, those who have read mankind a lesson in sanitary efficiency and for whom no other reward is possible? Again, Mr. President, accept our thanks for the latest chance to read into action our creed of duty.

We have been in the past nobly equal to every task laid on us, and, perhaps, sir, we may hopefully look forward to seeing in some future cabinet a secretary of health, who will enable us to do on a larger scale what we have so admirably effected in the far-sown islands of the sea.

DR. RODMAN, introducing Dr. William H. Welch, said: It is now the highest honor that can come to one of our profession to be chosen president of the national Association. Thrice on the Lupercal did Caesar put aside the crown offered by Mark Antony, but, it is said, each succeeding time more gently than before. It is within the knowledge of many here that he whom I shall next present, and who is now the honored president of the Association had, before his election, more than thrice put the crown from himself, and in a way that left no one to doubt that this gentle, wise and excessively amiable man could, when necessary, be as impregnable as Gibraltar itself.

I unhesitatingly declare that he has done more for American medicine than any medical man since Samuel D. Gross; for while possessing an unusual gift for conceiving and directing "big things," he has not been tied down by the exactions inseparable from private practice. Therefore has he conceived and directed great clinical hospitals and experimental laboratories, and has been the chief inspiration to more medical teachers and molders of thought in various cities and pathological laboratories of America than any living man. To-day he is in the Hopkins School or Hospital, in Baltimore; to-morrow, in the Rockefeller Institute in New York; and the next day, directing the Foundation in Washington; leaving on the midnight train for Chicago to run the American Medical Association. I introduce to you Dr. William H. Welch.

The American Medical Association

DR. WILLIAM H. WELCH, president of the American Medical Association: The city of Philadelphia has had a large share in making the medical history of this country. To-night it is contributing an event unique and memorable in the reception by this medical club of the President of the nation as its guest of honor. This is an event in which the whole medical profession of this country cannot fail to rejoice and take pride, and I esteem it a high privilege, Mr. President, to be permitted to offer to you, in behalf of the American Medical Association, our cordial greetings and best wishes, and to express to you our profound appreciation and great pleasure in the honor conferred by your presence on this occasion. Permit me especially to express the appreciation and thanks which I am sure all physicians in this country would desire me to offer for the inspiring words which you have spoken and for the fine tribute which you have paid to the work of members of our profession in our colonial possessions. Your voice will carry to the larger public that record of achievement which should be a source of pride to the whole country and to the world.

The American Medical Association, with an actual membership approaching 40,000 and with a much larger potential membership, represents the organized medical profession of this country. During the sixty-five years of its existence it has been a great unifying force, which has reflected the conditions and the progress of American medicine. By improving medical education, [illegible] standards of professional conduct, by [illegible] of beneficial medical and sanitary laws, by protecting physicians and the public from frauds, by promoting the science and art of medicine, by preaching the gospel of public health, and in various other ways this Association has rendered important service, not to the medical profession alone, but also to the people as a whole.

The great conquests over disease which have been set forth to-night so clearly and fittingly by the President are wholly the result of a remarkable extension of our knowledge during the last three decades into the nature and causes of the infectious diseases, which are the diseases of the greatest racial and social significance to mankind. At no previous time in the world's history could such a record of triumphant achievement have been attained. It is in the power of man to control to-day great pestilences, such as yellow fever, cholera, pernicious malaria and the plague, and even more devastating, although from their familiarity less dreaded diseases, such as tuberculosis, typhoid fever and infantile diarrhea, because Koch and Pasteur and Ross and Reed and a host of workers in the new fields of bacteriology have discovered how these diseases originate and spread, and have thereby placed sanitary practice on a rational and scientific foundation. It is immensely gratifying that our country has been able to furnish to the world the most striking example in the history of preventive medicine of the conquest of a great scourge by the extirpation of yellow fever through the discoveries of Reed, Carroll and their colleagues of the Army yellow fever commission and the practical application of these discoveries by Colonel Gorgas—all names of undying fame. These, as well as all of the discoveries in this domain, are triumphs of the experimental methods of research.

We know that you, Mr. President, in your administrative duties in the Philippines, in Cuba and on the Isthmus, have been brought into close touch with this life-saving work of physicians and sanitarians, the results of which, as you have authoritatively stated, constitute the greatest of our services to the peoples of these possessions, and we know also that you have aided and furthered this work in important ways by your advice, cooperation and sympathy. I desire on this occasion, on behalf of my colleagues of the medical profession, to pay tribute to the great services which you have thus rendered, and to the intelligent and sympathetic interest which you have repeatedly manifested by word and by deed in the cause of public health.

Public hygiene and preventive medicine have acquired an economic and social significance among the organized forces of civilization but little appreciated to-day by the general public or by legislators and administrative officers of government. They occupy a field quite apart from systems and schools of medical practice. The great International Exhibition of Hygiene, which has just been opened in the city of Dresden, affords an impressive demonstration of the methods and results of public health administration and activities, and of every kind of effort in the conservation and promotion of the health of the peoples of the world. It is deplorable and greatly to our discredit that of all the civilized nations of the world ours is the only one not officially represented in this international exhibit. We have, however, an opportunity to make partial amends for this slight dereliction by adequate governmental support and vigorous efforts in behalf of the success of the International Congress of Hygiene and Demography to be held in the city of Washington in September, 1912, on the invitation of our federal government.

It is a remarkable and significant fact that in order to make an impressive showing of what our country has done for public health we have to pass beyond the boundaries of this broad land which we inhabit and tell of what we have done for the peoples of distant islands and on the Isthmus of Panama; and it is true that our nation has organized better for scientific and practical sanitary work in these possessions than it has done at home.

We have a few highly efficient municipal and state departments of health, but we should have many more. The contributions of the Massachusetts State Board of Health to the principles of purification of public water-supplies and of sewage disposal, and of the New York City Department of Health to the administrative control of tuberculosis are recognized everywhere as of the highest importance. The state of Pennsylvania is setting the pace for the rest of the country in liberal support and efficient conduct of its department of health.

The activities of the Public Health and Marine-Hospital Service, our chief national health agency, have greatly improved and extended in recent years on both the scientific and the practical sides, but a larger and better plan of organization of our federal health agencies is urgently needed.

The health of the people is the greatest asset of the nation and should be the first consideration of governments. The interest of medical men in this subject differs in no respect from that of the rest of the community, nor is this interest longer confined to the medical profession. It is incredible that any one who has any realization of the suffering, inefficiency and enormous waste to the country resulting from preventable disease and insanitary conditions of living and of work can fail to appreciate the incalculable benefits to our people which would accrue from larger hygienic activities of the national government in ways entire consonant with our form of federal government and within the proper scope of such government.

Did our federal government not fall so far short of its plain duty in the way of promotion of public health, we should find here at home records of as beneficent achievement as those which have been cited from distant lands, and our own people would reap the full benefits of that ever-advancing knowledge of disease and its prevention, which carries its messages of hope to mankind.

Dr. Rodman, introducing Dr. Charles A. L. Reed, said: We have heard from the distinguished President of the American Medical Association, who has told us of its achievements and its purposes. I shall next present a man who had much to do in making the Association what it is, for it was under his presidency that the epoch-making reorganization occurred. A Cromwell was needed and the alert, the lion-hearted, the determined president of 1901 was equal to every constructive and parliamentary emergency at the meeting in St. Paul.

Moreover, he, as Chairman of the Committee on National Legislation, has served not only the profession, but the public in a way that few appreciate. As a member of the committee for ten years, together with the distinguished gentleman who has just spoken, I know something of the splendid work he has done in bringing about necessary and wholesome changes for both profession and public.

Although living in the Middle West and carrying on an extensive practice, he never hesitated to go to Washington when the call of duty was sounded. He recked not whether it was the Army reorganization bill, the pure food law, or the Dodds bill under consideration. He was always there and his presence was an inspiration to his followers, and a dismay to opponents.

I present to you the Queen City's best-known surgeon and author, the fellow-townsman and admirer of our distinguished guest—"one not in the rôle of common men"—Charles A. L. Reed.

National Medical Legislation

Dr. Charles A. L. Reed, Cincinnati: The Medical Club of Philadelphia stands for much in this country. It typifies not only fraternity, organization and effective ultraism, but shows the strength and vitality of the present-day movement, not only to lengthen but to broaden and to make happier the span of human life. That movement is fortunate in having here to-night such a leader as President Taft has shown himself to be. As Governor-General of the Philippines, he established medical education on a governmental basis in that country. As Secretary of War, as I happen to know, he cut the bands of red tape that officious officialdom had wrapped about Colonel Gorgas and that were hampering him in the very sanitary administration that alone has brought the great engineering achievement at the Isthmus within the range of possibility. So with the sanitation of Cuba, the reorganization of the Medical Corps of the Army, the enforcement of the pure food law and the development of the great Red Cross organization, President Taft has shown himself the actual leader in the very movement in behalf of the people to which movement alone the medical profession stands consecrated.

What shall be the next forward step? What are some of the conditions to be met? The people of this country are dying from preventable causes alone at the rate of more than one a minute. This is an impressive fact whether viewed from an economic or humane standpoint. It is likewise impressive that Congress has failed to furnish an adequate national mechanism to assist in staying this havoc, a havoc that is equivalent five times over, to the death every year of every officer and man in both the Army and Navy of the United States. It is true that we have some public health agencies scattered throughout five departments of the Government and it is likewise true that each of five members of the Cabinet takes a whack at being national health officer. This, of course, is all very absurd and, as I know from personal investigation in Europe only last summer, it makes us the laughing-stock of the world. But Congress seems to be destitute of pride as it appears to be destitute of interest in this subject. It seems to be sorely afflicted with constitutional lawyers who have been authoritatively defined by President Taft as lawyers who have ceased to be lawyers and gone into politics. These wiseacres seem to think it constitutional for the government to educate the people to protect swine but not to educate them how to protect themselves against disease. They seem to think it incontestably constitutional to control interstate commerce but entirely unconstitutional to control the sanitation of that commerce; or, in other words, they assume that the healthfulness of an interstate commodity is no attribute of that commodity at all. They concede that the government can and does exercise jurisdiction over the navigation and commerce of interstate waterways but contend that it has no right so to regulate the sanitation of such waterways as to make such navigation and commerce possible. In the Ohio Valley we have a thousand miles of river and a thousand miles of typhoid; from which it would seem to be entirely constitutional for the United States to use its streams for the dissemination of disease and the destruction of the people.

The derelictions of Congress in dealing, for instance, with the plague condition in this country cannot be hidden by its surreptitious expenditure of a half million dollars epidemic fund every year in fighting conditions many of which ought never to have become established. I could lengthen this indictment against Congress by giving you a fresh count every minute for an hour. It is enough to say that for every one of the more than 600,000 deaths from preventable causes in the United States every year each member of Congress has a certain measure of individual responsibility. The sooner he is made to feel that responsibility and feel it by votes of the people, the better. As the President has just stated, clearly the next step forward must be a more highly evolved national health service. Whether "department," "bureau," "commission" or "board" it should be so constituted that every available agency and every branch of modern science shall be brought to bear in solving the complex problem of human health and human efficiency.

Dr. Rodman, introducing Surgeon-General Stokes, said:

The sister service, the Navy, is in every sense the equal of the Army—they cannot be dissociated—and by its ability, its chivalry and cosmopolitanism, has so maintained the credit of our country in foreign lands as justly to cause it to be one of the chiefest prides of the American profession. No wiser and better administrative act was ever done than that which placed medical officers in command of hospital ships. If hospital ships are necessary, and assuredly they are, who else can so well command them as well equipped surgeons? We have with us to-night one who commanded the hospital ship *Relief* in the now famous cruise around the world. He originated a war plan which adds to the military efficiency of the fleet, attends to the humanities of battle, and bids fair to revolutionize some features of naval warfare. The judgment he displayed, together with his executive ability and charming personality, caused him to be promoted to the honorable post of surgeon-general—a position that he now adorns, and should for many years adorn. "He has a head to contrive, a tongue to persuade and a hand to execute."

I take great pleasure in presenting one, who, though surgeon-general and holding the rank of admiral, likes to be caned plain doctor—Charles F. Stokes.

The Sanitary Organization of the Navy

Dr. Charles F. Stokes, Surgeon-General, U. S. N.: With the exception, possibly, of medicine and surgery, no branch of science has been more completely revolutionized than that of naval warfare. Not only has this great change been effected in ships and personnel, but in spirit and aims. Spars, sails and wooden hulls have given way to the grim monsters of steel that carry our flag to-day. The change in the personnel has been almost as radical. The agile, cat-like top men, of the age of spars and masts, have been replaced by the seaman-mechanic, the gunner-mechanic and mechanics of other sorts. The muzzle-loading rifle, of decidedly indifferent effectiveness, has given way to the high-powered breech-loading rifle with smokeless powder, and a projectile of almost a ton of metal. Instead of, as in the past, having its field of usefulness limited largely to the treatment of sick sailors, the Medical Department of the Navy, to-day stands side by side with the fighting branches in adding to military efficiency and all that has to do with making the winning of battles possible.

You physicians in civil life are giving considerable attention to the so-called occupational diseases. Those diseases have been for a long time the subject of careful study by naval medical officers, not on economical and humanitarian grounds, as they would interest you, but on the score of pure military efficiency; for example, the solution of the problem of sustaining life in disabled submarines is a complex proposition. It is something more than simply generating oxygen and removing carbon dioxid; it has to do with the so-called fatigue-poison, hydrogen given off by batteries, the gasoline emanations, and so on. The men who manipulate the search-lights must be screened from actinic rays, otherwise their sight is seriously damaged. Ears must be prepared for and protected against the blasts of gun-fire. The continuous use of telescopic sights by gun-pointers frequently leads to serious impairment of vision. It is on these men that we must rely for accuracy of fire. The constructors may give us stable battleships, the ordnance officers high-powered rifles, and the commanding officers may maneuver the ships with consummate skill; still, if the men who point the guns cannot see straight, we are not going to have hits, and the outcome of battle may hinge on this remediable defect.

An ophthalmologist of recognized ability is studying the vision of gun-pointers in the Atlantic fleet, and without doubt the crippling effects of this industrial disability will be averted and military efficiency thus very materially advanced.

Sanitation has made the building of the Panama Canal possible; with the completion of the canal the field of operations of the battleship fleet will be practically doubled; in other words, the Atlantic fleet will be placed within striking distance of the Pacific and conversely the Pacific fleet will become effective in the Atlantic. No more impressive demonstration of the value of sanitation to a military establishment could be pointed out.

Any war plan which fails to take into consideration the sanitary features of the problem—the term sanitary is used in its broadest military sense—and to benefit by the best advice obtainable along these lines, should be cast aside as incomplete and likely to break down under actual battle conditions. Such a plan, must, of necessity, be *one-sided*. Until recently the Atlantic fleet was so organized that, had it gone into battle, the breakdown in the medical department would have been one of the most appalling in history. This condition of affairs was the result of a one-sided development. The awakening of a new spirit in the Navy Department, one of coordination and cooperation, in other words team-work, with military efficiency as its prime object, has made the solution of this problem possible. It is perfectly plain that medicine and surgery, by virtue of what they are doing and have done to promote military efficiency, stand in the front rank of the fighting arms of the nation to-day, and any attempt unduly to subordinate them or to deprive them of the recognition that is their due should be combated to the bitter end.

If the regulations or the laws make it impossible to put into operation effective organization and administration, then the laws and regulations must be changed to meet the new conditions. If these conditions of naval warfare have been such as to relegate to oblivion wooden ships, sails and spars, and with them much of the romance of the sea, then there should be no hesitation in casting aside cherished traditions, often clung to tenaciously for the sake of these traditions themselves, to make way for practicality and effective accomplishment. Responsibility should be recognized by appropriate rank and in this, as compared with foreign navies in all branches of the service, there is much to be desired.

The watchwords of the Navy Department to-day—and these watchwords have been instilled into us by our illustrious Commander-in-Chief—are, first and foremost, military efficiency, to be accomplished by coordination and cooperation, team work, close scrutiny of expenditures, the avoidance of needless waste; in other words, effective practical economy. Organized along these lines it is safe to say that the Navy will give as good an account of itself in the future as it has in the past, and its very preparedness will make it a potent factor in maintaining peace.

Dr. Rodman, introducing Surgeon-General Torney, said:

There is no abler, more representative, more patriotic a body of soldiers on the face of the earth, whether in peace or on the firing line, than the Medical Corps of the United States Army. It has not only demonstrated this ability and patriotism in times of war, when almost superhuman strength and courage were necessary to attend properly to the large number of wounded entrusted to its care, but it has done even more in peace, by demonstrating the cause of yellow fever and malaria, and ameliorating the terrors of each. The heroic and self-sacrificing experiments of Carrol, Reed and Lazear can never be forgotten either by their medical confreres or humanity for whom they died.

The Medical Corps of your Army, Mr. President, made it possible to build the Panama Canal after others had signally failed in this audacious and world-astounding enterprise. It was placed in such command, sir, by your orders as secretary of war. Its work has been characterized by Dr. Mitchell as "[illegible]" and so successful was the operation that [illegible] operator, was unanimously elected Pres[illegible] Medical Association.

We have with us this evening the distinguished head of this corps, a man, "modest, kindly, all accomplished, wise." I now call upon and introduce to you that surgeon, soldier, gentleman—General George H. Torney.

Sanitary Progress in Fort and Field

Dr. George H. Torney, Surgeon-General U. S. A.: Of the records of the history of our country there are none more interesting than those of the Medical Department of our Army. It began at the siege of Boston in 1775. Without going into details it will suffice to state that no adequate provision was made for its administration until it was forced upon Congress by General Washington, because of the large *morbidity* and *mortality* rates amongst the troops of the Revolutionary Army.

At the end of the Revolutionary War the Army was practically disbanded, and its medical department went out of existence. After the War of 1812 there was a reorganization of the Army, but in this reorganization the Medical Department received scant consideration.

Engaged in that war was Assistant-Surgeon Beaumont, who was destined to make his name in the medical history of his country. In 1822 Alexis St. Martin, of whom you have all read, suffered from a wound of the stomach, which was finally cured, leaving a fistula. Fortunately for science he fell under the care of Surgeon Beaumont and when in 1825 the wound of the stomach of Alexis St. Martin had healed, Surgeon Beaumont began his experiments in the study of the physiology of digestion. In the light of history Beaumont should be given the credit as the first *scientific* investigator in physiology in our country. For it was he who instituted and carried out his investigations with all the acuity so well illustrated by modern methods. His work will endure forever.

The Mexican War brought to the Medical Department of the Army a grave responsibility in the care of the sick and wounded, and also the management of epidemics in a foreign land, and those of you who have had experience in this work will appreciate the labor involved in the solution of such problems. In this connection it must be remarked that the medical department of an army on a peace basis is inadequate in personnel for war, and this statement applies to all other armies as well as our own. The very suggestion for adequate provision of the medical department of an army seems to appall the administrative authorities of the service.

When the Civil War began the Medical Department of the Regular Army was small in numbers, and on it was thrust the medical administration of a vast army which, through the early part of the war, could not be made efficient because of inadequate personnel and lack of appreciation of its needs.

The Civil War developed Jonathan Letterman, a surgeon of the Army, of whom but a few of you have heard, but whose name stands out most prominently in the medical history of the War of the Rebellion. It was he who organized and administered the Medical Department of the Army of the Potomac under a system which was adopted by other armies in the field. There was much opposition to his policy of administration, but the War Department and Congress ultimately recognized its merit.

At that period the Medical Department had frequently 80,000 patients under its care. Exceptionally these numbers ran over 100,000, and in one instance 120,000 patients. To-day Letterman's system for the administration of the medical affairs of the Army of the Potomac has been adopted as original by the military authorities of Europe without credit to its author, and with no mention of the United States.

After the termination of the Civil War the medical and surgical history of the War of the Rebellion was written by the officers of the Medical Department of the Army ,and to-day it stands as a monument of the industry of the men who engaged in this work. At the same time was begun the Index-Catalogue of the Library of the Surgeon-General's Office. At first it was a pamphlet of twenty small pages; to-day it is the greatest work of its kind in the world.

From the end of the War of the Rebellion to the beginning of the Spanish War, the Army of the United States was occupied in subduing the hostile Indians on what was known as the frontier. In these wars the officers of the Medical Department were fully engaged with their brothers of the line and exposed to the same dangers. At the outbreak of the Spanish War the personnel of the Medical Department was inadequate in numbers for the care of its own sick, and the sudden increase in the volunteer forces, for which no adequate provision had been made, added to its burden.

During this war a board composed of Vaughan and Shakespeare of the volunteer forces and Reed of the regular Army investigated the epidemic of typhoid fever which preveailed in the volunteer Army. The conclusions of this board are valuable to our profession. It is my belief that it proved that typhoid fever is a contact disease in the majority of cases.

After the Spanish War investigation was immediately begun in the study of tropical diseases, which resulted in proving by the board of which Walter Reed, surgeon, United States Army, was the directing head, that the mosquito is the intermediate host for carrying the infecting toxin of yellow fever. Of the brilliant results that followed this investigation you all know. It was due to this discovery that Gorgas, in Cuba, was enabled to stamp out yellow fever, and on his transfer to Panama, as chief sanitary officer, following the same methods to prevent the development of the disease on that Isthmus. It was this discovery, also, that enabled Kean of the Medical Corps of the Army, in Cuba in 1906, as chief sanitary officer of that island, to stamp out yellow fever after it had recurred in that island; and by his efforts to establish a department of public health which is to-day a model for the world. Measured in terms of money it is estimated that the discovery by Reed has already more than paid the cost of the Spanish War, the Philippine War and of the construction of the Panama Canal. I wish also to mention Ashford of the Medical Corps of the Army, who in 1902 began his investigations in Porto Rico as to the cause of the anemias among the inhabitants of that island. His report, with Dr. King of the Marine-Hospital Service, that the hookworm was the parasite that causes a large percentage of disability in tropical countries, was published in 1904.

To-day the Army Medical Department is engaged in an antityphoid campaign for the prevention of that dread disease. This campaign has followed the work of the typhoid board, composed of Musser, Thayer, Lambert, Vaughn, O'Reilly, Russell, Councilman and Flexner. To-day, in Texas, there is a division of the United States troops, every man of which is vaccinated against this infection. In that division not a single case of typhoid fever, which is the disabling disease of armies, has occurred. In the Spanish War typhoid fever developed in 90 per cent. of all the regiments within eight weeks after their organization.

I hope that the import of this statement will be fully impressed on you, since, from a medical point of view, this is history.

Tropical Medicine.—The eighth annual meeting of the American Society of Tropical Medicine will be held in New Orleans, May 18-19, under the presidency of Dr. William S. Thayer, Baltimore. The society will be the guest of the Orleans Parish Medical Society and part of the sessions will be held in its new building. At the morning session on May 18, held in this place, the president's address will be given and papers on malaria will be read. At the afternoon session, held in the Richardson Memorial, Tulane Campus, leprosy will be the topic. On the morning of May 19 there will be a clinic on pellagra at Charity Hospital, and at the morning session, held in the Hutchinson Memorial, Tulane Medical Department, there will be papers and a general discussion on amebiasis. The afternoon session at the same place will be devoted to the election of officers and members, and to papers on pellagra, yellow fever, snake poison, etc. An excursion to the Louisiana Leper Home has been arranged for May 20. The committee of arrangements extends a general invitation to all who are interested and requests those who are coming to notify the chairman, Dr. J. Birney Guthrie, Suite 602, Perrin Building, New Orleans.

LONDON LETTER

(From Our Regular Correspondent)

London, April 29, 1911.

Proposed Compulsory Opening of Windows

The antituberculosis campaign has had great effect in educating the public as to the importance of fresh air, and windows are now kept open to an unprecedented extent. But the compulsory opening of windows is a step which the most ardent hygienist would not dream of advocating in this country, in which the liberty of the individual is valued so highly and the house has been called the "Englishman's castle." However, the health committee of the Paddington Borough Council (one of the metropolitan boroughs) has recommended for adoption the following new by-laws for tenement houses: "It shall be compulsory for all windows of sleeping apartments to be opened wide for at least two hours a day, and for floors to be swept once a day and washed once a week." It is proposed to appoint inspectors with right of entry into the houses to see that the regulations are observed. The maximum penalty for breach of these laws will be $25, and $10 for each day the offense is continued.

The Seventeenth International Congress of Medicine

Arrangements are being made for the seventeenth International Congress of Medicine which will be held in London on August 6-12, 1913. The University of London, the Imperial College of Science and Technology and the City and Guilds College have expressed their willingness to put rooms at the disposal of the congress. It has been decided that the sections of laryngology and otology will be allotted two adjoining rooms and that the councils of these two sections shall arrange their programs in a conjoint meeting, and that their transactions shall be published in one volume and supplied to each member of the section. A section of radiology will be included in the congress. The section of pathology will include a subsection of chemical pathology. A section of anesthesia, both general and local, will be established. Sections XX and XXI of the last congress will be so altered that one section will be devoted to naval and military medicine and another section wholly devoted to tropical medicine. The following alterations have been made in the titles of the sections: Section III, from general and experimental pathology to general pathology and pathological anatomy; Section IV, from bacteriology and pathologic anatomy to bacteriology and immunity; Section XVIII, from hygiene and immunity to hygiene and preventive medicine. Papers introducing subjects for discussion will be previously printed and distributed to all the members of the section who have intimated their intention to take part in the discussion and to any members who may apply for them. The introductory papers cannot be printed in all the four official languages, but abstracts of them will be printed, as was done at the last London congress. In each section, the morning sessions will be devoted to discussions on subjects of interest to be selected by the officers of the sections. Each discussion will be introduced by not more than two speakers, to be selected by the officers of the section, with due regard to the international character of the meeting. It shall not be permissible to read the introductory papers already printed, but a time not exceeding twenty minutes shall be allowed to each introducer to read and elaborate an epitome of his introductory paper. Subsequent speeches in the discussion shall not exceed ten minutes. None but the introductory speakers shall be invited by the officers of the section to take part in the discussion. At the morning session no papers other than on the subjects set down for discussion shall be taken up, unless the general discussion has terminated before the hour fixed for the termination of the morning section. The afternoon session shall be devoted to papers offered by the members of the section. The staff of the section shall have the power of selection from among the papers offered. Not more than fifteen minutes shall be allowed for the reading of any such paper nor more than five minutes for any speech discussing it.

The Cambridge Hospital for Special Diseases

At Cambridge a very small but remarkable hospital was founded five years ago for the study of special diseases by some of the leaders of the profession—Sir Clifford Allbutt, Professor Osler, Sir William Church, Sir Jonathan Hutchinson, Sir Richard Douglas Powell, Sir Henry Morris, Sir W. Watson Cheyne, Sir Victor Horsley and Sir Donald MacAlister. The objects for which the hospital were established were thus stated by the committee: "Much and fruitful research has been done in acute diseases, but there are many chronic and widespread maladies which have not yet received the attention they deserve. These, though not commonly immediately fatal to life, incapacitate the sufferer from active work, cause great pain and misery, and finally leave the victim helpless and entirely dependent on the kindness and charity of his friends or of strangers. Patients suffering from these diseases, owing to the slow progress and long continuance of their illness, are not suitable for reception into general hospitals, which as a rule admit by preference cases of the more acute diseases. The mode of origin or progress of these affections is very imperfectly known, and little therefore can be done in the way of their rational treatment. The great need of scientific research on these chronic diseases has been strongly felt by the medical profession for many years." At present, the hospital is lodged in a small private house containing four beds, and for the most part is supported by subscriptions from physicians. A bulletin giving the results of the work of the staff is issued from time to time. Rheumatoid arthritis is one of the subjects which has been investigated. Though no great advance in knowledge can be chronicled yet much careful work has been done which clears away prevalent misconceptions and may make a path for future advances. The house which is used as a hospital is small and in many ways inconvenient. It has therefore been decided to build a small hospital for which a site of one acre on the outskirts of Cambridge has been secured. The plans have been drawn up. There will be a consulting room, library, three rooms for research, a photographic dark room and a room for *x*-ray apparatus. The cost is estimated at $8,000.

The Teaching of Hygiene in Elementary Schools

Dr. Addison, lecturer on anatomy at St. Bartholomew's Hospital and liberal member of parliament for Hoxton, has introduced a valuable bill: "to require that in public elementary schools instruction shall be given in hygiene, and to girls in the care and feeding of infants." This bill is in no sense a party measure and has received the support of more than 200 members of the house on all sides. Its first reading has been carried unanimously. Since the bill was first introduced last year the principal health officer of the local government board has stated in one of his reports that the provision of this instruction would greatly prevent the waste which has caused so much pauperism in Great Britain. Of late years there has been considerable quickening of the public conscience in this matter, and owing to the efforts of various associations and the voluntary work of teachers and public authorities there has been a remarkable diminution in infant mortality. Nevertheless, one child in every three dies under the age of 5 years, and one out of every five under the age of 12 months. The number of children who die under the age of 5 years amounts to 150,000. The causes are manifold: bad sanitation, crowded rooms, poverty, etc. But Dr. Addison does not hesitate to say that at least 50,000 die as a direct or indirect consequence of parental ignorance. This is particularly true for the manufacturing districts of the north. In the fifteen large Lancashire towns with a population of 3,000,000 the death-rate for the summer quarter of last year was 30 per cent. higher than in London, and this was mainly due to infant mortality. In the town of Burnley, which has an unenviable reputation, the health officer attributes one-fifth of the deaths to the fact that the mothers work in factories and leave their children in charge of ignorant persons.

Plague in India

The recrudescence of plague in India was announced in a previous letter to THE JOURNAL. In reply to a question in parliament, Mr. Montague, the under secretary for India, stated that the situation was very seriously regarded by the authorities who had been hopeful of a permanent diminution, and had made every effort to stamp out the disease. In the central provinces of Agra and Oudh alone the deaths from plague amounted to 43,508 in February and 95,884 in March.

The Lowest Birth-Rate and Death-Rate on Record in Scotland

A short time ago the lowest birth and death-rates on record in England were reported in THE JOURNAL. A similar announcement has just been made with regard to Scotland. The birth-rate for 1910 was 25.16 per thousand and the death-rate 14.66, the lowest figures ever recorded.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, April 28, 1911.

Illegal Practice of Medicine in the Pharmacies

The Syndicat médical de Paris has just made an attempt to come to an understanding with the Syndicat des pharmaciens de Paris et de la Seine on the question of the illegal practice of medicine in the pharmacies. Unfortunately, after two entire sessions devoted to the joint examination of the important questions interesting the two professions, it appeared evident that the point of view of the physicians and that of the pharmacists were irreconcilable. The delegates from the Syndicat des pharmaciens asserted that the illegal practice of medicine was forced on them by the public and that their business existence depended on it. If one druggist were to refuse to sell non-toxic drugs, the customer would merely go to another pharmacist. The delegates of the Syndicat médical de Paris replied that the simplest drugs might in certain cases be harmful, or at least, useless, and might, if only by causing the patient to lose precious time, become dangerous. The delegates of the Syndicat des pharmaciens then proposed that pharmacists should be granted the right to sell once to a customer commonly used drugs, without a prescription, at the same time urging the patient to find a physician before coming again. This proposition was evidently too contrary to the law of the practice of medicine and pharmacy to be accepted. A medical society, charged with the duty [illegible]sts of the medical profession, could not [illegible] of approving a tolerated violation of law.

The delegates of the medical society proposed that a notice like the following should be posted in all of the pharmacies which wished to accept it, and especially in those of the members of the pharmacists' society: "In accordance with the laws which regulate the practice of medicine and pharmacy, in order to safeguard strictly the responsibility of pharmacists and in the interests of its health, the public is invited, in case of any indisposition, to call in a physician, since any delay in medical intervention may entail irreparable consequences, which might be avoided by the judicious attentions which can be given only by a physician." The pharmacist delegates, however, considered the proposition impracticable. They merely proposed to aid physicians to prosecute for such overt instances of illegal practice of medicine as consultations in the rear of the shops, and systematic dressings, etc., given to patients. They were also willing to take part in a newspaper campaign of publicity with regard to the danger of asking a druggist for drugs without a physician's prescription.

Similar divergencies came to view on the subject of the renewal of prescriptions. According to the law, druggists have no right to deliver drugs on old prescriptions, whether they call for toxic substances or not. The law on this point is violated daily, and the delegates of the Syndicat des pharmaciens declare that this violation is forced on them by the habits of the public. To regularize their irregular situation, they proposed the following principle: "Every prescription which does not bear the words 'not to be renewed' may be filled again." The delegates of the medical association, on the other hand, proposed the following rule, which is in accordance with the spirit of the law and guarantees the safety of the people: "No prescription may be renewed by a druggist, except those on which the physician shall have written the words 'to be renewed.'"

Other divergencies also appeared on the question of the delivery of drugs without prescriptions. The pharmacists expressed a wish that a list of drugs not to be delivered without prescriptions should be drawn up, while the physicians wished that a list should be made of the only drugs which the pharmacist would have the right to sell without prescriptions. Agreement was not reached on any of these points.

Personal

In its session of April 25, the Académie de médecine elected as national correspondents, Dr. Blanquinque of Laon and Dr.

Laguesse, professor of histology at the Faculté de médecine de Lille.

Improvements in the Hospitals

The municipal counsel of Paris has just authorized the expenditure of $2,000,000 (10,000,000 francs) for improvements in the following hospitals: the Hôpital Cochin, the Hôtel-Dieu, the Bicêtre, the Hôpital des Enfants-Malades, the marine sanatorium of Hendaye, situated on the Bay of Biscay, and the Nouvelle-Pitié.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, April 20, 1911.

Personal

In place of Professor Matthes, Professor Moritz of Strasburg has been nominated for first place for the internal medical clinic at Cologne, and it is rumored that Moritz has accepted the call. The singular circumstances that a man should go from a university to an academy and thus sacrifice his position is explained by the fact that Moritz soon after his appointment at Strasburg alienated from himself the physicians of that place and did not possess the faculty of securing himself in his present position. It is to be hoped that this experience will stand him in good stead in his new place.

Inoculation of Syphilis in Rabbits

Professor Uhlenhuth, director of the imperial health office in Berlin and soon to be professor of hygiene in Strasburg, reported, at a recent meeting of the *Berliner medizinische Gesellschaft*, the inoculation of rabbits with syphilis. The injections were made into the testicles and into the blood vessels. By further inoculations into other animals, sixteen transmissions were secured and in this manner the virulence was raised so that the inoculations yielded 100 per cent. of successes. Clinically three forms could be distinguished: Erosions of the scrotal skin, chronic inflammation of the testicle and periorchitis. Histologically the lesions resembled those of human syphilis and contained many spirochetes. Moreover, Uhlenhuth and his coworkers were able, by the injection of very virulent rabbit material into the circulation of other rabbits, to induce general syphilis in these animals. In the circulating blood of these animals living spirochetes could be demonstrated. General syphilis could be produced also in monkeys through the circulation. In the discussion that followed this paper the skepticism which Professor v. Hansemann expressed regarding the etiologic significance of *Spirochæta pallida* for syphilis was remarkable. He admits that the spirochete plays a certain rôle in syphilis, but he doubts that it causes the disease since it is not found in the tertiary forms. In the products of the inoculation there could be found many deviations from the manifestations typical of human syphilis. The other speakers opposed this skepticism with the exception of Dr. Siegel, who used to champion other ameba-like germs as the cause of syphilis. Uhlenhuth asserted in closing that the same symptoms were found in the infected monkeys as in man. That no spirochetes are found in gummas is not singular as even in tubercles it is sometimes impossible to demonstrate tubercle bacilli. He added that malaria parasites have not yet been grown in pure culture, and yet no one doubts their etiologic significance.

Age and Tuberculosis

The Prussian national statistical office has recently published a review of the mortality from tuberculosis in Prussia according to sex and age for 1908 and 1909. In an article in the *Zeitschrift für Tuberkulose* B. Frankel reproduced these tables and remarks that they demonstrate the progressive diminution in the death-rate from tuberculosis. In 1908 there died in Prussia, 63,320; in 1909, 60,871. For 100,000 living there were in 1908 16.40, in 1909, 15.59 deaths from tuberculosis. The mortality from tuberculosis in the first year of life shows in 1908 the high percentage of 26.86 per 100,000 living, the highest in any of the age classes, but in 1909 it was only 23.65. The death rate from tuberculosis of children from 1 to 15 years old has never since 1881 reached so low a figure as in 1909. While in 1881 the deaths numbered 11,000, and in 1902 they were more than 13,000, in 1909 they amounted only to 10,621.

Ward for Pay-Patients at the Moabit City Hospital

At the last session of the city council this new departure which I have previously mentioned was inaugurated. A physician belonging to the Sozialdemokratische party opposed this move as essentially an introduction of class distinctions into the municipal hospitals. He declared that every preference of the better as against the poorer classes was an evil. He was of the opinion that such an arrangement would work prejudicially to the general care of the sick. He wanted no class distinctions in the municipal hospitals and opposed it also on account of the financial interests of the city. In reply to this the mayor emphasized the pressing need of meeting the requirements of the middle classes in the way proposed. Care should be taken to bring the arrangements already present into an orderly legitimate system. He was convinced that by the establishment of a second class, the level of the third class would be raised. So long as class distinctions existed they must be recognized. As a matter of fact there are many people who for certain reasons cannot apply to the municipal free hospitals, who yet are unable to pay the high prices charged by private sanatoria, or for medical treatment at home, without actually impoverishing themselves. If the city should devote a small portion of the public funds to the assistance of these people, a good work would be accomplished. There is no occasion for any uneasiness on the part of the medical profession in view of this undertaking.

Disinfection of Books

Under the heading, "The Spread of Infectious Diseases by Printed Matter," Dr. Trautmann, who is at the head of the state hygienic institute in Hamburg, presents a very interesting article in the *Zeitschrift der Schulärzte*. The possibility of conveying infection by printed matter must be admitted although positive evidence of its occurrence can seldom be furnished. It is evident that circulating libraries constitute an especial danger in this respect. The conveyance of tuberculosis is especially to be feared, because this disease is wide-spread, usually runs a chronic course, giving opportunity for literary recreation for a long time, and further the bacillus is readily deposited on objects by coughing and the disease germs have an extraordinary capacity of resistance. Naturally other diseases can be conveyed in the same way. The use of books at school is not without danger. There is possibility enough for transmission of disease by means of text-books and books from the school library. England, America and Austria have possessed for a long time the beginnings of an official regulation for the disinfection of books. Until a few years ago, however, Germany has had no effective and harmless method for this purpose.

Books are difficult objects to treat; neither dry heat nor streaming steam at 100 C., neither sulphur dioxid nor cold formaldehyd gas gives satisfactory results. At present a solution of the question appears to have been reached and by two entirely different processes. The method of Findel and Xylander consists in the application of hot air at a temperature of 75-80 C. (167-176 F.) with a relative humidity of 30-40 per cent. or even up to 80 per cent. The moist heat acts essentially by conduction and radiation. Unfortunately sterilization by this process requires a considerable length of time. The process for a single disinfection of closed books, and the process is intended for these, requires two days. Moreover only the vegetating forms of bacteria are killed, the resting forms not being affected.

In Glaser's quicker acting modification of this method, air at 98-100 C. and a humidity of 60 to 80 per cent. is employed with the addition of formaldehyd, but there are objections to this method, which seems to be injurious to the books. Trautmann proposes another process which he considers more reliable. He bases it on the investigations of Esmarch and Kister. He calls attention to the process introduced three years ago with the so-called "Hamburg apparatus" which depends on the operation of a stream of steam evaporated under reduced pressure and saturated with formaldehyd at a low temperature. This process has worked well in the disinfection of furs, skins, leather, silk and velvet goods, and is also well suited to the disinfection of books, butterflies, stuffed animals, etc. The most important point is that the Hamburg process operates with streaming saturated steam but at a low temperature, and does its work in a short time, more effectually and at a lower cost. A complete disinfection does not take longer than ninety minutes at the most.

A condition for the successful action of the Hamburg apparatus is the careful spreading of the leaves of the book. It is not suited to the disinfection of closed, thick books or closely packed printed matter. Trautmann uses for the necessary spreading a stout rack in the form of a trough; another method consists in drawing back the covers of the books, tying

Herbert Milton Nash, M.D. University of Virginia, Charlottesville, 1852; the oldest and most esteemed physician of eastern Virginia; died April 26, at the Sarah Leigh Hospital, Norfolk, Va., from shock following an operation for the removal of gallstones, aged 79. After his graduation, Dr. Nash took post-graduate work for a year in New York City, and then began practice in Norfolk, and was the only survivor of the physicians who combated yellow fever in that city in the great epidemic of 1855. On the outbreak of the Civil War he was appointed assistant surgeon of the State Force of Virginia and later was made surgeon and corps surgeon in the Confederate service, where he served throughout the Civil War. He was a charter member of the Norfolk Medical Society and served for several terms as its president; a member of the Virginia State Medical Society and, at one time, its president; and at the time of his death an honorary fellow. He was also a member of the American Medical Association, American Public Health Association and the Southern Surgical and Gynecological Association. He was at one time vice-president of the Medical Examining Board of Virginia, president of the Norfolk Board of Health, president of the Board of Quarantine Commissioners of the district of Elizabeth River, and formerly quarantine officer. He was also a member of the staff of St. Vincent's and the Norfolk Protestant hospitals. In 1902, on the occasion of the fiftieth anniversary of the graduation of Dr. Nash from the University of Virginia, he was the guest of honor of the faculty of that institution. The Norfolk County Medical Society, at a special meeting, adopted resolutions expressing the personal and professional loss felt by its members in the death of its oldest and most esteemed ex-president and member.

Carlton C. Frederick, M.D. University of Buffalo, N. Y., 1881; a member of the American Medical Association, the American Gynecological Society, the American Association of Obstetricians and Gynecologists, president of the Buffalo Academy of Medicine and many local societies; adjunct professor of obstetrics in the medical department of Niagara University from 1883 to 1896, and clinical professor of gynecology in the University of Buffalo since 1897; one of the founders and surgeon in chief to the Buffalo Woman's Hospital, and a member of the staff for many years of the Buffalo General and St. Mary's Lying-In Hospitals; author of many monographs on gynecology and abdominal surgery; died at his home, April 30, from endocarditis, aged 55. At a special meeting of the Buffalo Academy of Medicine, action was taken on the death of Dr. Frederick and eulogies were pronounced by many of his colleagues.

Norman J. Pettijohn, M.D. Kansas City (Mo.) Medical College, 1884; formerly a member of the American Medical Association; a Federal soldier and later assistant surgeon of volunteers in the Civil War; formerly chief surgeon of the Kansas City, Fort Scott and Memphis Railroad, and later assistant chief surgeon of the Frisco system; for several years chief surgeon of the Metropolitan Street Railway Company of Kansas City; once president of the International Association of Railway Surgeons and of the Jackson County Medical Society; died at his home in Kansas City, April 22, aged 71.

Erasmus Van Meter Swing, M.D. University of Pennsylvania, Philadelphia, 1867; a member of the American Medical Association; president of the Coatesville, Pa., Board of Health and chief of staff of the Coatesville Hospital; who came to Philadelphia to attend the reception given President Taft by the Philadelphia Medical Club, May 5; died in the Bellevue-Stratford Hospital in that city, May 6, from acute gastritis, aged 70.

Jacob Dimmitt Norris, M.D. University of Maryland, Baltimore, 1878; a member of the Baltimore Clinical Society; president of the board of police examiners of Baltimore; formerly a member of the city council and vaccine physician; president of the local pension board and formerly mayor and surgeon of the Fourth Infantry, N. G., Maryland; died at his home in Baltimore, April 24, from heart disease, aged 67.

Harry Johnson Dean, M.D. Jefferson Medical College, 1890; a member of the American Medical Association and American Academy of Ophthalmology and Oto-Laryngology; eye, ear, nose and throat surgeon to the Hershey Memorial Hospital, Muscatine, Ia.; died at his home in that city, April 26, from nephritis, aged 42.

Edward W. Fox, M.D. Denver and Gross College of Medicine, Denver, Colo., 1904; a member of the Colorado State Medical Society and president of the Las Animas County Medical Society; a specialist in diseases of the eye and ear; died at his home in Trinidad, Colo., April 30, from disease of the lungs, aged 32.

James B. Morgan, M.D. Medical College of Georgia, Augusta, 1876; professor of anatomy and clinical surgery in his alma mater; sometime president of the Medical Association of Georgia and the Alumni Association of the University of Georgia; for several years president of the Augusta Board of Health and coroner's physician for Richmond County; a member of the State Board of Health; died at his home, April 23, aged 53.

Robert Caldwell, M.D. University of California, San Francisco, 1869; a member of the Medical Society of the State of California and a pioneer practitioner of San Jose; for several years a practitioner of Nagasaki, Japan; a member of the Western Union Telegraph Company's famous expedition through Alaska in 1867 and 1868; died at his home in San Jose, April 20.

Thomas Hamill, M.D. Eclectic Medical Institute, Cincinnati, 1855; Humboldt Medical College, St. Louis, 1867; Missouri Medical College, St. Louis, 1868; acting assistant surgeon in the army during the Civil War; for twenty years a member of the board of pension examiners of Johnson County, Kan.; died at his home in Olathe, March 18, aged 85.

Henry Allison Lathrop, M.D. Hahnemann Medical College, Chicago, 1881; New York University, New York City, 1890; a member of the American Medical Association; a member of the Wisconsin state legislature in 1887; died at his home in Marshfield, Wis., April 25, from cerebral hemorrhage, aged 61.

Thomas Hodge Johnson, M.D. Eclectic Medical Institute, Cincinnati, 1879; a veteran of the Civil War; for several terms superintendent of schools of Laclede County (Mo.); a member of the Missouri legislature for three terms; died at his home in Springfield, April 24, aged 70.

Cornelius Sampson Jackson, M.D. Harvard Medical School, 1865; assistant surgeon of the Thirtieth Massachusetts Volunteer Infantry during the Civil War; a member of the Boston Surgical and Gynecological Society; died at his home in Hudson, Mass., April 22, aged 67.

Richard E. Johnson, M.D. Miami Medical College, Cincinnati, 1856; a member of the American Medical Association and a life member of the Ohio State Medical Association; president of the First National Bank of Lima; died at his home in Gomer, April 24, aged 76.

Lewis S. Brown, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1873; a member of the Missouri State Association, and for several years president of the Knox County Medical Society; died at his home in Edina, April 21, from arteriosclerosis, aged 75.

Vesley Marvin Newcombe, M.D. University of Vermont, Burlington, 1884; a member of the New Hampshire Medical Society; a physician of Somersworth, and a numismatist of note; died at his home, April 25, from cirrhosis of the liver, aged 50.

Cameron Piggot, M.D. University of Maryland, Baltimore, 1882; dean of the academic department and professor of chemistry and geology in the University of the South, Sewanee, Tenn.; died at his home in that place, April 30, aged 55.

George Bruce Thomas, M.D. University of Alabama, Mobile, 1898; of Maysville, Ky.; died in the Hord Sanitarium, Shelbyville, Ind., April 8, from the effects of corrosive pois believed to have been self-administered with suicidal int aged 45.

Alfred H. Caviness, M.D. Baltimore University Sch Medicine, 1901; a member of the Medical Society of of North Carolina; died at his home in High Falls from septicemia, the result of a carbuncle of the nec

Lewis H. Kirk, M.D. University of Pennsylvania, phia, 1877; a member of the American Medical A and local United States pension examining surgeon; his home in Oxford, Pa., April 26, from heart disease,

John Worthing Hurlbert, M.D. Cleveland Univer Medicine and Surgery, 1877; formerly a member American Medical Association; died at his home in Ohio, April 24, from carcinoma of the stomach, aged

Thomas Jefferson Largen, M.D. Texas Medical Coll veston, 1874; of San Antonio; formerly a member State Medical Association; a Confederate veteran; died home of his son in San Antonio, April 23, aged 70.

John Clayton Abernathy, M.D. University of Na (Tenn.), 1866; a prominent practitioner of East Ten and a Confederate veteran; died at the home of his Chattanooga, April 20, from senile debility, aged 87.

Robert I. Bowie, M.D. Royal University of Munich, Ba 1880; formerly a practitioner of San Francisco, but for years a resident of Nagasaki, Japan, where he foun hospital; died in the latter city, April 24, aged 52.

them together over the back of the book and hanging a row of books thus treated on the rods in the Hamburg apparatus. Xylander unites the two methods in one. The proposed method of disinfection kills all disease germs and does not injure the books in any way. Trautmann's claims have been confirmed by a thorough trial by Xylander and Glaser. Gärtner selects alcoholic steam for disinfection, but this method is not to be recommended because the disinfection takes a long time and injures the books.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, April 25, 1911.

The Repeated Use of Prescriptions

In this country the doctor's prescription is handed back to the patient by the apothecary who has made it up, only the date of the prescription being added by him. Very often the latter rule is not strictly adhered to; thus the patient is enabled to obtain the remedy for an indefinite number of times. By such means, crimes and suicides have been committed repeatedly here within a short time, lately. Therefore, a memorandum has been presented to the ministry of the interior by medical associations, and the necessity of strict adherence to the existing rules emphasized. Shortly afterward, all druggists and pharmacists, as well as doctors, were admonished by an ordinance of the ministry to turn their attention to the abuse of medical prescriptions by patients. The law requires that every filling of a prescription be marked on it by the dated stamp of the dispenser. If "heroic" remedies or strong poisons and other narcotic substances are contained in the prescription, the doctor should add how often the patient may have it made up by writing down: *Ne repetatur*, or *Repetatur semel*. Attention is chiefly drawn to the hypnotic and narcotic substances of modern chemistry, which are not yet contained in the "poison list," but which are most often the object of repeated administrations by the patients. On this point the interests of the public are coincident with those of the profession, although naturally the impossibility of obtaining a remedy without consulting a physician will be found an unpleasant difficulty by many easy-going patients.

Marriages

Francis Winslow Johnson, M.D., Glyndon, Md., to Miss Marion Lawrence Reese, at Baltimore, April 24.

Davis Thomas Bowden, M.D., Paterson, N. J., to Miss Helen W. Bryce of Passaic, N. J., April 19.

Raymond H. Gaynor Laub, M.D., Brooklyn, N. Y., to Miss Lucretia Ferris of Elmira, N. Y., April 24.

John Richard Callaway, M.D., to Miss Luella Louise Wingfield, both of Kansas City, Mo., April 29.

Andrew Johnson Brown, M.D., The Dalles, Ore., to Miss Marie Wetzel of Portland, Ore., April 20.

James Southall Wilson, M.D., to Miss Julia Gardiner Taylor, at Williamsburg, Va., April 17.

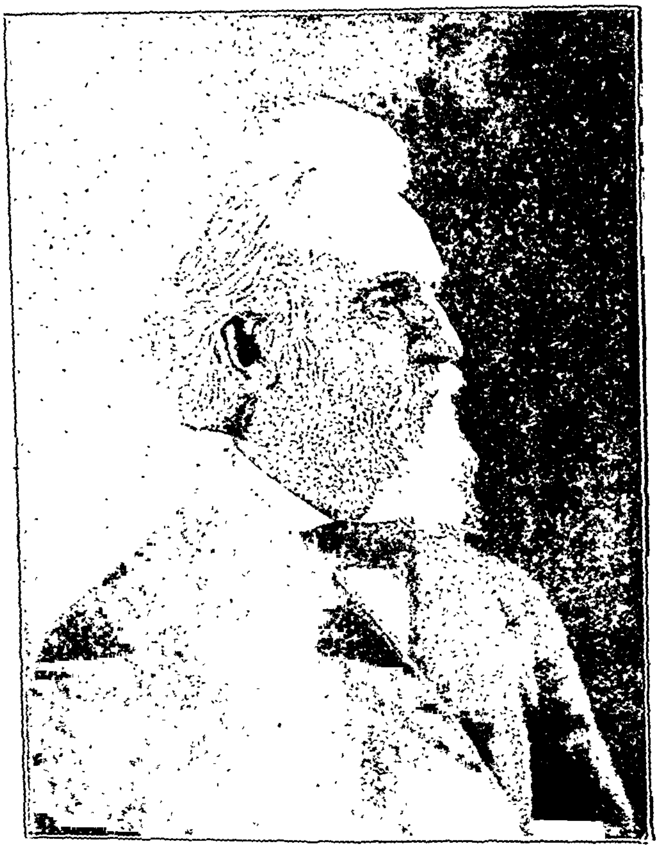
Arthur H. Meyers, M.D., Mystic, Conn., to Miss Helen M. Barker of East Orange, N. J., April 21.

Peter H. Jobse, M.D., to Miss Minnie Fitzgibbon, both of Milwaukee, April 26.

Deaths

Isaac Newton Danforth, M.D., one of the best beloved of the older physicians of Chicago; died at his home, May 5, from heart disease, aged 75.

Dr. Danforth was a descendent in direct line of Nicholas Danforth who landed in Massachusetts Bay in 1634. His paternal grandfather and three uncles were physicians before him and this naturally turned young Danforth's mind toward medicine. He graduated from Dartmouth Medical School, Hanover, N. H. in 1862, and was given the honorary degree of A.M. by Dartmouth College nineteen years later. After four years of practice in New Hampshire, Dr. Danforth located in Chicago where he soon attained high rank as a practitioner and teacher.



I. N. Danforth, 1836-1911

His work as a medical teacher commenced in 1868, when he became instructor in chemistry at Rush Medical College. Three years later he was made lecturer of pathology; in 1873 president of the spring faculty and in 1881 professor of pathology. His work in Northwestern University Medical School began in 1882, when he was made professor of pathology. From 1887 to 1895 he was professor of clinical medicine in that institution. In 1876 he became professor of pathology in the Woman's Hospital Medical College, which afterward became Northwestern University Woman's Medical School, and continued in this position for nineteen years; and for four years thereafter was dean of the faculty and professor of internal medicine.

He became attending physician to St. Luke's Hospital in 1870 and continued in that position until 1895. For the first ten years of the existence of Wesley Hospital, he was chief of its medical staff; for many years he was pathologist to Cook County Hospital, and consulting physician to various hospitals in Chicago for thirty years past.

His society membership included the American Medical Association, the Association of American Physicians, the Chicago Pathological Society, of which he was once president, and he was one of the founders and first president of the Society of Medical History of Chicago.

Dr. Danforth was a frequent contributor to the medical literature, and more especially of late years, on the lines of medical history and biography; in 1907 his life of Dr. Nathan Smith Davis was published. Dr. Danforth's chief recreation was in the line of history and his collection of Americana was of more than local repute.

In 1909 Dr. Danforth founded a medical missionary hospital in Kiu Kane, China, in honor of his first wife, Elizabeth Skelton Danforth.

He had not been in robust health for a long time, but was confined to his house for only about three weeks. He had been a sufferer with asthma for a long while, but his death was due to valvular disease of the heart.

As a general practitioner, Dr. Danforth was exceptionally successful. He was one of the first in Chicago and the Northwest to use the microscope in pathology. He was a man of steadfast conviction, of most exemplary life and stood always for the best in all things. His death will be deplored by his many friends and by the hundreds of men and women in the profession all over the world whom he has helped, both materially and by wise counsel.

Herbert Milton Nash, M.D. University of Virginia, Charlottesville, 1852; the oldest and most esteemed physician of eastern Virginia; died April 26, at the Sarah Leigh Hospital, Norfolk, Va., from shock following an operation for the removal of gallstones, aged 79. After his graduation, Dr. Nash took post-graduate work for a year in New York City, and then began practice in Norfolk, and was the only survivor of the physicians who combated yellow fever in that city in the great epidemic of 1855. On the outbreak of the Civil War he was appointed assistant surgeon of the State Force of Virginia and later was made surgeon and corps surgeon in the Confederate service, where he served throughout the Civil War. He was a charter member of the Norfolk Medical Society and served for several terms as its president; a member of the Virginia State Medical Society and, at one time, its president; and at the time of his death an honorary fellow. He was also a member of the American Medical Association, American Public Health Association and the Southern Surgical and Gynecological Association. He was at one time vice-president of the Medical Examining Board of Virginia, president of the Norfolk Board of Health, president of the Board of Quarantine Commissioners of the district of Elizabeth River, and formerly quarantine officer. He was also a member of the staff of St. Vincent's and the Norfolk Protestant hospitals. In 1902, on the occasion of the fiftieth anniversary of the graduation of Dr. Nash from the University of Virginia, he was the guest of honor of the faculty of that institution. The Norfolk County Medical Society, at a special meeting, adopted resolutions expressing the personal and professional loss felt by its members in the death of its oldest and most esteemed ex-president and member.

Carlton C. Frederick, M.D. University of Buffalo, N. Y., 1881; a member of the American Medical Association, the American Gynecological Society, the American Association of Obstetricians and Gynecologists, president of the Buffalo Academy of Medicine and many local societies; adjunct professor of obstetrics in the medical department of Niagara University from 1883 to 1896, and clinical professor of gynecology in the University of Buffalo since 1897; one of the founders and surgeon in chief to the Buffalo Woman's Hospital, and a member of the staff for many years of the Buffalo General and St. Mary's Lying-In Hospitals; author of many monographs on gynecology and abdominal surgery; died at his home, April 30, from endocarditis, aged 55. At a special meeting of the Buffalo Academy of Medicine, action was taken on the death of Dr. Frederick and eulogies were pronounced by many of his colleagues.

Norman J. Pettijohn, M.D. Kansas City (Mo.) Medical College, 1884; formerly a member of the American Medical Association; a Federal soldier and later assistant surgeon of volunteers in the Civil War; formerly chief surgeon of the Kansas City, Fort Scott and Memphis Railroad, and later assistant chief surgeon of the Frisco system; for several years chief surgeon of the Metropolitan Street Railway Company of Kansas City; once president of the International Association of Railway Surgeons and of the Jackson County Medical Society; died at his home in Kansas City, April 22, aged 71.

Erasmus Van Meter Swing, M.D. University of Pennsylvania, Philadelphia, 1867; a member of the American Medical Association; president of the Coatesville, Pa., Board of Health and chief of staff of the Coatesville Hospital; who came to Philadelphia to attend the reception given President Taft by the Philadelphia Medical Club, May 5; died in the Bellevue-Stratford Hospital in that city, May 6, from acute gastritis, aged 70.

Jacob Dimmitt Norris, M.D. University of Maryland, Baltimore, 1878; a member of the Baltimore Clinical Society; president of the board of police examiners of Baltimore; formerly a member of the city council and vaccine physician; president of the local pension board and formerly mayor and surgeon of the Fourth Infantry, N. G., Maryland; died at his home in Baltimore, April 24, from heart disease, aged 67.

Harry Johnson Dean, M.D. Jefferson Medical College, 1890; a member of the American Medical Association and American Academy of Ophthalmology and Oto-Laryngology; eye, ear, nose and throat surgeon to the Hershey Memorial Hospital, Muscatine, Ia.; died at his home in that city, April 26, from nephritis, aged 42.

Edward W. Fox, M.D. Denver and Gross College of Medicine, Denver, Colo., 1904; a member of the Colorado State Medical Society and president of the Las Animas County Medical Society; a specialist in diseases of the eye and ear; died at his home in Trinidad, Colo., April 30, from disease of the lungs, aged 32.

James B. Morgan, M.D. Medical College of Georgia, Augusta, 1876; professor of anatomy and clinical surgery in his alma mater; sometime president of the Medical Association of Georgia and the Alumni Association of the University of Georgia; for several years president of the Augusta Board of Health and coroner's physician for Richmond County; a member of the State Board of Health; died at his home, April 23, aged 53.

Robert Caldwell, M.D. University of California, San Francisco, 1869; a member of the Medical Society of the State of California and a pioneer practitioner of San Jose; for several years a practitioner of Nagasaki, Japan; a member of the Western Union Telegraph Company's famous expedition through Alaska in 1867 and 1868; died at his home in San Jose, April 20.

Thomas Hamill, M.D. Eclectic Medical Institute, Cincinnati, 1855; Humboldt Medical College, St. Louis, 1867; Missouri Medical College, St. Louis, 1868; acting assistant surgeon in the army during the Civil War; for twenty years a member of the board of pension examiners of Johnson County, Kan.; died at his home in Olathe, March 18, aged 85.

Henry Allison Lathrop, M.D. Hahnemann Medical College, Chicago, 1881; New York University, New York City, 1890; a member of the American Medical Association; a member of the Wisconsin state legislature in 1887; died at his home in Marshfield, Wis., April 25, from cerebral hemorrhage, aged 61.

Thomas Hodge Johnson, M.D. Eclectic Medical Institute, Cincinnati, 1879; a veteran of the Civil War; for several terms superintendent of schools of Laclede County (Mo.); a member of the Missouri legislature for three terms; died at his home in Springfield, April 24, aged 70.

Cornelius Sampson Jackson, M.D. Harvard Medical School, 1865; assistant surgeon of the Thirtieth Massachusetts Volunteer Infantry during the Civil War; a member of the Boston Surgical and Gynecological Society; died at his home in Hudson, Mass., April 22, aged 67.

Richard E. Johnson, M.D. Miami Medical College, Cincinnati, 1856; a member of the American Medical Association and a life member of the Ohio State Medical Association; president of the First National Bank of Lima; died at his home in Gomer, April 24, aged 76.

Lewis S. Brown, M.D. College of Physicians and Surgeons, Keokuk, Ia., 1873; a member of the Missouri State Association, and for several years president of the Knox County Medical Society; died at his home in Edina, April 21, from arteriosclerosis, aged 75.

Vesley Marvin Newcombe, M.D. University of Vermont, Burlington, 1884; a member of the New Hampshire Medical Society; a physician of Somersworth, and a numismatist of note; died at his home, April 25, from cirrhosis of the liver, aged 50.

Cameron Piggot, M.D. University of Maryland, Baltimore, 1882; dean of the academic department and professor of chemistry and geology in the University of the South, Sewanee, Tenn.; died at his home in that place, April 30, aged 55.

George Bruce Thomas, M.D. University of Alabama, Mobile, 1898; of Maysville, Ky.; died in the Hord Sanitarium, Shelbyville, Ind., April 8, from the effects of corrosive poison believed to have been self-administered with suicidal intent, aged 45.

Alfred H. Caviness, M.D. Baltimore University School of Medicine, 1901; a member of the Medical Society of the State of North Carolina; died at his home in High Falls, April 29, from septicemia, the result of a carbuncle of the neck, aged 53.

Lewis H. Kirk, M.D. University of Pennsylvania, Philadelphia, 1877; a member of the American Medical Association and local United States pension examining surgeon; died at his home in Oxford, Pa., April 26, from heart disease, aged 60.

John Worthing Hurlbert, M.D. Cleveland University of Medicine and Surgery, 1877; formerly a member of the American Medical Association; died at his home in Uniopolis, Ohio, April 24, from carcinoma of the stomach, aged 58.

Thomas Jefferson Largen, M.D. Texas Medical College, Galveston, 1874; of San Antonio; formerly a member of the State Medical Association; a Confederate veteran; died at the home of his son in San Antonio, April 23, aged 70.

John Clayton Abernathy, M.D. University of Nashville (Tenn.), 1866; a prominent practitioner of East Tennessee and a Confederate veteran; died at the home of his son in Chattanooga, April 20, from senile debility, aged 87.

Robert I. Bowie, M.D. Royal University of Munich, Bavaria, 1880; formerly a practitioner of San Francisco, but for many years a resident of Nagasaki, Japan, where he founded a hospital; died in the latter city, April 24, aged 52.

due to the carelessness of employees." Before the carelessness of employees can be urged as an excuse, it must first be shown (1) that the discipline is such that the railroad has every right to expect obedience and carefulness in general; (2) that the proved character of the employee in any responsible post is such that the road has every right to expect faithfulness from him; and (3) that the conditions of operating are such as, on the one hand, to leave as little room as possible for disaster resulting from carelessness, and, on the other, to place no undue strain on the employee's strength and capacity.

It is gratifying to see that the reputation of these roads, with respect to their care of human life, is highly valued. This augurs well for the improvement of whatever conditions may still remain to be improved.—EDITOR.]

Who Should Apply the Wassermann Test?

To the Editor:—This week I was approached by one who styles himself a chemist asking me to instruct him in the Wassermann reaction. The following copy of the reply which I mailed to him is self-explanatory:

"*My Dear Sir:* Your inquiry yesterday, in regard to my willingness in teaching you the details of the Wassermann reaction, has received the most earnest *consideration* by me. Heretofore I have refused no one who wished to know this work. All such applicants, however, have been physicians.

Personally I should like to teach each one who is interested. The prevalent opinion in Germany to-day is that only trained serologists should do this work. In a recent number of the *Münchener med. Wochenschrift*, K. Taege asserts that only his *ability* as a physician has enabled him to interpret difficult reactions, made by himself, satisfactorily in given cases.

To avoid being personal and prejudiced in this matter, however, I determined to place your letter in the hands of Dr. Paul G. Woolley, director of the laboratory of the Cincinnati Hospital, and to be guided by his decision. Dr. Woolley is of the opinion that I could not give you a certificate, after a period of instruction in this work, stating that you are fully competent to make a correct reading in every case which may come to you for analysis, because of your lack of medical training.

Since you asked me at the end of a period of instruction to give you a certificate stating that at such time you would be fully competent to do this work, and inasmuch as, according to the opinion of Dr. P. G. Woolley, a recognized authority in pathology, I would be unable to do so, I must refuse the offer you so kindly made me."

I am a staunch supporter of the medical profession, and I believe that none but a physician is capable of passing judgment on the question as to whether a given patient is luetic or not. Experience has shown us how difficult this reaction may become in many instances. The physicians of this state are busily engaged in trying to have the optometry bill vetoed, and I think that we all should be equally active in trying to prevent laymen from practicing medicine in any other of its branches. Furthermore no physician ought to give a certificate to any one certifying to his competency to practice any branch of medicine, and least of all in a case of this kind in which a man absolutely without a knowledge of general medicine and its ethics might affiliate himself with the advertising "venereal quack," and become a harpy to prey on the people.

This man now intends to go East with the hope of finding some physician willing to instruct him, and then to return here with a certificate announcing his fitness.

OSCAR BERGHAUSEN, B.A., M.D., Cincinnati.

An Observation Bearing on the Causation of Sex

To the Editor:—I noticed in THE JOURNAL (April 22, 1911, p. 1228) an abstract of a paper by W. W. Kain, "Can the Sex of the Family be Controlled at Will by the Parents?" Kain is said to agree with E. R. Dawson that the supplying ovary is in reality the essential factor in the causation of sex, the right ovary producing the male and the left ovary the female. I believe that a study of the chromosomes with their adjunct sex chromosomes, etc., will dispel any such notions. But that is too big a subject for this letter. I wish at this time only to report a case that came under my observation last October. A girl married at the age of 14; at the age of 15 she gave birth to a boy, and at 17 to a girl, following which she had three miscarriages produced by herself with a catheter. About two weeks following her last miscarriage she died of lobular pneumonia, at the age of 19. Necropsy revealed a tuberculous cavity in the right apex the size of an English walnut, a serofibrinous pleurisy of the right side, a pericarditis with effusion, no inflammation of the pleura of the left side but the pneumonic condition as bad on the left side. The pelvic area showed no evidences of the miscarriages. There was, however, a congenital absence of the left tube and ovary, of which there was not even a remnant, the broad and round ligaments being apparently normal. The right ovary and tube were perfectly normal. Dr. A. E. McDowell assisted me.

W. O. WISNER, Spokane, Wash.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

VENTILATION IN THE PUBLIC SCHOOLS

To the Editor:—I wish to get some information about ventilation of public schools. The system in use in our school, and in a large number of schools in New Jersey, is based on the idea that carbon dioxid is heavier than air, which is correct at a certain temperature. The inlet for pure air is placed near the ceiling, in the expectation that the vitiated air will be forced downward to the outlet near the floor. To my mind this reverses the laws of Nature. Gases will expand when heated, volume increased, specific gravity lessened. Just imagine a class of little children seated in a kindergarten on little chairs having the impure air forced down on them in order to get it out through the outlet! When the room is heated to about 70 F. (the transoms and windows and doors closed with this system), does the carbon dioxid rise to the ceiling? If so, why not let it out there? Being a medical inspector, I would like some light on the subject. JOSEPH PAYNE, Midland Park, N. J.

ANSWER.—You will find much information about ventilation and heating in the following books:

Shaw, W. N.: Air Currents and the Laws of Ventilation, 1907. Cambridge Univ. Press.
Monroe, W. S.: Steam Heating and Ventilation, 1902, New York, Engineering Record Series.
Harrington: Practical Hygiene, 1902, Lea Brothers.
Notter, J. Lane: Treatise on Hygiene, 1908, Blakiston.

You state that the inlet for pure air is near the *ceiling* but do not say whether the incoming air is warm or cold. The problem is one of heating as well as ventilation. If the incoming air is warm it will tend to remain near the top of the room. If the outlet is high in the wall the warm air will tend to pass out without either warming the room or materially changing the air of the room. If the outlet for air is at the floor the warm air after raising the temperature of the room will sink and pass off at the bottom.

Carbon dioxid itself in the quantity ordinarily found in rooms is harmless. It is simply taken as an indicator of vitiated air. The amount of carbon dioxid added to schoolroom air by respiration is slight, seldom more than 10 parts per 10,000. Experiments have shown that people confined in small, tight compartments endure without any symptoms of illness or discomfort an atmosphere containing 150 parts of carbon dioxid per 10,000, provided the temperature and moisture are kept low. Tests in crowded schoolrooms under similar conditions show that the pupils are unaffected. Results are different if the temperature is allowed to rise to 70 F. and the humidity is high. It seems well established that results commonly attributed to poor ventilation are not *due to any change in chemical composition* of the air but to physical changes. The solution of the problem of ventilation lies in the maintenance of the normal heat interchange between the body and the surrounding air.

Whether expired air will rise or sink depends on several factors, its temperature, amount of CO_2, moisture content and the temperature of the surrounding air. Taking what is perhaps an average density for expired air, if the temperature of the surrounding air is below 81 F. the expired air will tend to rise. The expired air will tend to sink if the temperature of the surrounding air is above 81 F. and neither rise nor fall if the surrounding air is at this critical temperature. The expired air will sink to the floor after rising and cooling, as it will tend to do in a room temperature of 70 F. unless the flow of air downward made by forced draught is overpowering.

The preparation has been analyzed by the British Medical Association's chemists, who reported:

"Analysis showed the presence of potassium iodid, guaiacum resin, extract of licorice, powdered licorice, starch, mineral matter—apparently a mixture of talc and kaolin—a resinoid substance, and a trace of alkaloid. . . . The quantities of the various ingredients are estimated as accurately as possible, and the following formula was indicated:

"Potassium iodid	1.8 grains
"Guaiacum resin	0.8 grain
"Extract of licorice	1.0 grain
"Resinoid (phytolaccin?)	0.9 grain
"Powdered licorice	1.7 grains
"Rice starch	2.0 grains
"Talc and kaolin	2.1 grains"

The variability of nostrums of this type is well illustrated by the fact that a sample of Gloria Tonic analyzed by Dr. Aufrecht of Berlin showed a different composition from those tablets analyzed by the British chemists. Aufrecht, in an article that appeared in the *Pharmazeutische Zeitung*, June 8, 1910, reported: "The Gloria Tonic Tablets examined consisted essentially of 26.76 per cent. potassium iodid and 2.81 per cent. iron (probably in the form of iron saccharate)."

The price charged for a box of fifty tablets of Gloria Tonic is $1; the estimated cost of the ingredients in these fifty tablets is 16 cents.

Correspondence

The Railroads and Human Safety

To the Editor:—In The Journal, April 15, 1911, p. 1113, after citing the list of accidents shown by the accident bulletin of the Interstate Commerce Commission for July, August and September, 1910, you refer to "the deliberate, cynical disregard of human safety which foreign observers are prone to consider an American characteristic," and say: "When the people are awakened to the possibilities and the necessities of the whole situation, there will be a change."

I beg to call your attention to the Act of Congress, passed April 14, 1910, prescribing the kind and location of safety appliances on all cars engaged in interstate commerce, which, as testified in hearings before the Interstate Commerce Commission, will involve expense on the railroads of $55,000,000. When the commission held hearings preliminary to determining what regulations should be enforced under this law, the railroads offered no objection to the essential features of plans proposed for fully equipping all cars with uniform safety appliances, notwithstanding the enormous expense involved.

J. W. Watson, chief inspector of safety appliances of the Interstate Commerce Commission, in his report for 1909, says:

> "As showing the care with which the safety appliances demanded by the law are being maintained, it may be noted that while the railroads dispensed with the services of a great many employees to meet the economies necessitated by falling off of business in 1907, the force of men employed to maintain safety appliances suffered the least curtailment of any. As a result the condition of equipment continued to improve during the slack period of 1908-09, the year just closed showing the least percentage of defective equipment of any years since the law became operative, notwithstanding that the number of cars examined by our inspectors was 125,000 greater than in any previous year. As indicating the great improvement that has taken place within the past five years, it may be stated that the defects per thousand cars inspected in 1905, numbered 309.56, while for the year 1909 the figure is 74.65.
>
> "It is only proper to say that the attitude of most presidents and general managers of railroads has contributed greatly to the good results accomplished. As a rule such officials are in thorough sympathy with the aims and purpose of the law. They have earnestly striven to meet its requirements and have cheerfully cooperated with the commission to secure its effective enforcement."

In his report for 1910 Mr. Watson states that the average of defects found per 1,000 cars had decreased to 65.33 during the year.

The Interstate Commerce Commission's reports show that while in 1900, 67.6 per cent. of the total railway equipment of the United States was fitted with train brakes, in 1910, 99.1 per cent was so fitted. In 1900, 94.3 per cent. of the total equipment was fitted with automatic couplers, while in 1909, 99.3 per cent was so fitted.

The large railroads of the United States paid out for injuries to persons in their transportation departments for the year ending June 30, 1909, $17,705,333. Even were railroad managers controlled by a "deliberate, cynical disregard of human safety" this large payment, which does not fully represent the cost of railway accidents, appears sufficient to cause them to exercise every precautionary measure of safety.

Statistics of the Interstate Commerce Commission will show that a large percentage of railroad accidents are due to the carelessness of employees. Although much railroad legislation has been enacted during the past several years, and a great deal of it in favor of the railway employees at their initiative, no act has ever been passed making it a crime for a railroad employee to disregard a signal or to disobey a rule.

During the railroad rate hearings held by the Interstate Commerce Commission last autumn, many representatives of railroads cited the need of safety appliances, abolition of grade crossings and more substantial construction in general as leading to future increase of expenditure.

While the number of railroad accidents in the United States is greatly in excess of accidents in European countries, yet the conditions of construction here and abroad are very dissimilar. The railroads of Europe were constructed through thickly settled regions and substantial construction was necessary from the beginning.

In the United States the railroads have been largely pioneer enterprises in advance of traffic. The need to get the track down so that the commerce might be served was paramount. So rapid has been the growth of railroad construction that the single track mileage operated in the United States has grown from 192,556 miles in 1900 to 235,402 miles in 1909. At the same time, the rapid growth of population in this country has tended everywhere to render inadequate systems of railroads constructed in comparatively recent years. Vast sums are now being spent in the elimination of grade crossings and for other improvements to promote safety of operation.

In view of these facts, is it quite fair to refer to "deliberate, cynical disregard of human safety" as the attitude of the railroads? Is not the showing that the railroads have made in the interest of greater safety an indication that railroad men are awake to the necessities of the whole situation?

Charles E. Kern, Assistant to Director,
Bureau of Railway Economics, Washington, D. C.

[Comment.—We are glad to give space to this letter, since, as our correspondent has misapprehended our intent, others may have done the same.

We did not impute "deliberate, cynical disregard of human safety" to the interstate railroads, as a class. It will be remembered that the instance cited was one of disregard of human safety by an urban street railway, which, in spite of warnings, since amply justified, laid its tracks so close together that any one caught between two moving cars was almost certain to be crushed and killed. No words can be too strong to characterize the conduct of a road operated under conditions such that the presumption is, from the outset, that loss of life must result. Such conditions exist and they endanger the public. We are glad to believe, however, that such conditions have grown very rare among the railroads to which our correspondent refers.

Our correspondent will doubtless admit that even here there is still much room for improvement. We fear that the weak point in the defense of these railroads is indicated in the statement that "a large percentage of railroad accidents are

MICHIGAN

The legislature has adjourned. The following bills have become laws: A bill to require physical training to be taught in the city schools; a sane Fourth of July bill; a bill placing all maternity hospitals under the state board of health and a bill to require local boards of health to report all cases of tuberculosis. The chiropractic bill was defeated.

MISSOURI

The legislature has adjourned. No bills of special interest to the medical profession have been enacted. The optometry bill was defeated.

NEBRASKA

The legislature adjourned April 2. A bill was passed to establish a board of control for state institutions, also bill to establish a state tuberculosis hospital and appropriating $40,000 for its maintenance. An appropriation of $75,000 was made for the enlargement and maintenance of the state orthopedic hospital. An appropriation of $100,000 was made for new buildings for the state hospital for the insane.

NEW HAMPSHIRE

The legislature has adjourned. A bill to consolidate the three existing boards of medical examiners into one, failed to pass. An optometry bill became a law. An osteopathic bill was defeated. A bill to forbid the use of common drinking-cups became a law.

OHIO

The legislature is still in session.

OKLAHOMA

The state legislature has adjourned. An optometry bill became a law.

OREGON

The legislature has adjourned. A bill to empower the state board to prosecute illegal practitioners failed to pass.

PENNSYLVANIA

The legislature is still in session. No laws of special interest to physicians have been adopted. A bill to provide for a single board of medical examiners has passed the senate and is now in the house. A midwifery, a neuropathic and an optometry bill are in committees.

TEXAS

The legislature has adjourned. The sanitary code drafted by the state board of health was enacted as a part of the statutes. A state tuberculous sanatorium and a state leprosarium were established.

UTAH

The legislature has adjourned. A new medical practice act was passed, also a bill to require physicians and midwives to report all cases of blennorrhea in new-born children within six hours of its appearance.

WISCONSIN

The legislature is still in session. No laws of interest to physicians have as yet been passed.

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
Bowling Green, Kentucky

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Third Weekly Meeting

Causes of Sudden Death (Continued)

Death from Cold: Symptoms. Post-mortem appearances.

Death from Heat: Symptoms. Post-mortem appearances.

Death from Starvation: Acute and chronic. Symptoms. Post-mortem appearances.

Death from Electricity: From electric current, from lightning, or by electrocution. Post-mortem appearances.

Infanticide: By commission or by omission. Evidences of live birth. Appearances of lungs, hydrostatic test. Other organs and tissues. Duration of child's life. Cause and manner of death.

Society Proceedings

MISSISSIPPI STATE MEDICAL ASSOCIATION

Annual Meeting, held at Jackson, April 10, 1911

The President, Dr. J. W. Young, Grenada, in the Chair

A list of the officers elected was given in The Journal, April 29, page 1271.

Delegates to the Los Angeles Session of the American Medical Association were instructed to vote against the proposition to make membership in the state associations include membership in the national organization.

Addresses of welcome were made on behalf of the city of Jackson by Hon. A. F. Crowder, mayor of Jackson, and on behalf of the Hinds County Medical Society by Mr. W. H. Watkins. These were responded to by Dr. H. M. Folkes of Biloxi.

President's Address: Value of a Good Physician to the Public

Dr. J. W. Young, Grenada: I thank God that every real true physician is a gentleman; and an optimist, and an altruist, a "jolly good fellow," and an all-round good citizen—loyal to the flag, loyal to the courts, loyal to his patrons, loyal to everything that is good and true—but, alas, in so many instances he is not loyal to his fellows, or his state and county medical societies. We are altruists for everything and everybody except each other. Why can we not be colleagues rather than competitors? Instead of knocking, why can we not occasionally, at least, take a fellow-doctor by the hand and say: God bless you, my brother, I wish you well and hope you are prospering? No man in any community is more valuable to the public than a good, reliable physician. Others may bring personal comforts, wealth and material conveniences, but on the physician the people must rely to guard their physical welfare, without which wealth would be of little value. In mere money, the value of his services can never be counted.

Medicine in all ages has attracted to its ranks the most self-sacrificing members of society. Medical men stand alone on the earth, they only are striving with their whole might to extinguish their own business. They preach temperance, virtue and cleanliness, knowing well that when people come to follow their advice their occupation, like Othello's, is gone. The time has come when the medical profession must wake up to the fact that it has been largely ignored in the past. The heroism displayed and martyrdom suffered in the medical profession will never be known. There is a quietness about it that distinguishes it as true heroism. We hear little of the many instances of blood poisoning from treating a septic wound; of the brave stand against the most deadly epidemics, of physicians courting death in the most loathsome forms, away from the comforting touch of loved ones, that the sick and dying may not have to fight alone their battle with the pestilence. What a true physician could not be hired to do for all the money the world could offer, he will do joyfully and without expectation of reward, from the higher sense of duty and his love for mankind.

Physicians all over the land have given up their lives in efforts to save others, often leaving loved ones in penury and want. Has anyone ever said that they were heroes, or has any one ever proposed that their dependent ones should share in a hero fund? Nay, verily. The physician walks amid the ruin and desolation of pestilence; he goes forth to dare and do in a supreme effort to save the lives of his fellowmen. Think of the thousands who are being saved from untimely graves by and through the recent discoveries of medical and sanitary science. Think of what Reed and Carroll and Lazear did for mankind in subjecting themselves to the deadly virus of yellow fever to prove the mosquito origin of that disease. Think of what Jenner and Simpson, and Marion Sims, Crawford W. Long and Ephraim McDowell and Koch and others have done for the world. Nearly every organization of any kind has a pension fund. All Christian denominations provide funds for their aged and superannuated preachers. A fund is provided to pension all college professors after twenty-five years of service. All United States judges, from highest to lowest, and all army officers, whether they have seen any service or not, are permitted to retire on a pension at the age of 65. Every Union soldier is the recipient of a monthly stipend from Uncle Sam's treasury. A good physician who has literally worn himself out toiling and working to save the lives of others, when he is no longer able to work, has any one ever been heard to even suggest a pension for him? Nay verily. "Earth's heroes who have gone down in battle or who have been sacrificed to maintain their solemn convictions of duty to country or religion, deservedly receive the honor and praise given them. The hero dead who sleep in the National or Confederate cemeteries of the land are rightfully held in loving remembrance by the people of the sections for which they fought and died, and no one calls in question the homage paid them in holding them dear to memory," but there are other heroes just as deserving of praise, the many true and noble physicians who have died in the line of every-day duty, and gone down to death in the fulness of loyalty to that duty.

This is the life and character of a true physician, and this leads me to the inquiry: Why is it that we as physicians, individually and collectively, have so little influence, and fail so often to get the ear of our legislators? We have never asked for anything for our own personal benefit. All that we have ever asked for was looking to the general welfare of the commonwealth, and rather to our financial detriment than otherwise. It is because of the petty jealousies and the knocking in our own ranks. We are never a unit on anything. As an instance: Several years ago this association passed a resolution declaring that we would not examine for any of the old line insurance companies for less than $5.00, and only a few weeks ago an agent of one of these companies told me that they have an examiner in nearly every city and town in Mississippi and are only paying a minimum fee of $3.00. We always agree to disagree, and hence a house divided against itself must—as a matter of course—fall. Thus by our own action are we discredited by the public at large.

It is usually possible to get an appropriation from the legislature for the study and cure of animal diseases, but when physicians go before the legislature and state that 3,000 Mississippians are annually dying from the great white plague, and half as many from typhoid fever—both preventable diseases—and ask for an appropriation to stay the spread and ravages of these diseases, the door is slammed in our faces and we are charged with the fact that as physicians we cannot agree as to what we want.

On this occasion, therefore, I plead for harmony in our ranks—I plead for better feeling toward and more love for each other—I plead for a fuller exercise of the virtues and graces which should characterize the life of every true physician—I plead for a greater interest in our county and state associations. The very youngest of us has but a very few years on earth; then how much better we must feel when we come to die to know that we have always loved our fellows—to know that we have been kind and loving colleagues, rather than ugly and mean competitors.

Treatment of Chronic Tuberculous Sinuses with Bismuth Paste. Removal of Birth-Marks by Carbon-Dioxid Snow

Dr. S. H. McLean, Jackson, reported a case of tuberculous abscess treated with bismuth paste and one of nevus treated with carbon-dioxid snow. He described in detail the methods of using these remedies.

DISCUSSION

Dr. J. H. Fox, Jackson: Dr. Beck in treating tuberculous sinuses always administers the paste in liquid form to allow it to enter all cavities. He advises that it be applied warm. He also advises the placing of an ice pack over the sinus to prevent the bismuth paste running out. My attention was first called to carbon-dioxid snow by Dr. Gaskell. I have had splendid results with this treatment. I collect the snow in a manner similar to Dr. McLean's method. The time of application varies. In the case of black moles it must be applied longer than in some other cases.

Dr. W. C. Campbell, Memphis: These abscesses are better not opened. The treatment should not be begun until the sinus is three months old. About once a week or five days I fill the cavities. I have seen harm done by giving too much of this paste—with a little care this can be avoided.

Lobar Pneumonia in Infancy

Dr. B. H. Booth, Drew, living in a malarial district, is accustomed to use quinin in all cases of pneumonia and believes it shortens the course of the disease and lessens its severity. He discusses the variations in pathology and treatment in the disease in children as compared with these in adults.

DISCUSSION

Dr. S. S. Carother, Duck Hill: In my opinion, the danger in giving quinin during the progress of pneumonia is too great.

Dr. J. G. Gaither, Oxford: I use no turpentine, but petrolatum and mustard, 1 part mustard to 16 parts of petrolatum. The patient is anointed daily.

Dr. G. W. Wallace, Arbo: I keep these patients in bed and not in their mother's arms. They are allowed to nurse. The child should be kept very quiet.

Dr. B. S. Waller, Silver Creek: I have noticed great difficulty in breathing. I usually make a plaster with a few drops of turpentine, sometimes a little glycerin.

Dr. F. M. Brougher, Belen: It is necessary to keep the lungs warm. I have found quinin of no value in treatment of pneumonia.

Dr. B. H. Booth, Drew: I use quinin because it is a stimulant to a certain extent. In regard to keeping the child in bed, I should like to know how one can keep the child quiet so easily as in its mother's arms.

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Fifth Annual Meeting, held at Albany, April 18-19, 1911

(*Continued from page 1354*)

Discussion on Salvarsan (Concluded)

Dr. V. C. Pedersen, New York: I want to warn against the indiscriminate use of the intravenous injection of salvarsan; this is a surgical procedure of no small importance. It was my misfortune recently to have a case of nearly fatal collapse after the intravenous injection of this drug. Three weeks before the injection the man was examined very carefully as to his heart and arteries and kidneys and they were found to be normal, so far as one could judge in a man who had had syphilis for twenty-one years.

Dr. J. M. Swan, Watkins: I have recently had a patient with an infected antrum in whose case the infective organism was supposed to be the *Treponema pallidum* and in whom the

Wassermann reaction was said to be positive. The blood had been taken three times, twice from a finger puncture, and once from wet cupping of the back. In my opinion a Wassermann test made in this way is valueless and should not be interpreted as an indication for administration of salvarsan or any other antisyphilitic remedy.

Dr. Edward D. Fisher, New York: Mercury has a curative effect on syphilis, and so has salvarsan. Mercury is not supposed, by most of us, to have any curative effect on parasyphilitic conditions, such as general paresis or tabes. A few of the manifestations that may occur in tabes, such as ptosis, or ocular muscle paralysis, which have been shown to disappear by the use of salvarsan have been known also easily and quickly to disappear with the use of mercury. My position at present in reference to the use of salvarsan in organic nervous diseases is that probably this drug will be as ineffective as mercury. In view of its tendency to induce degeneration, and especially in certain nerve fibers, it is too dangerous a drug until we get further reliable information to use it in these diseases.

The Relationship of Tabes Dorsalis to General Paralysis; Are They the Same Disease Differing Only in Situation of the Lesion?

Dr. Edward D. Fisher, New York: While both diseases are parasyphilitic or metasyphilitic manifestations of a primary syphilis, tabes in its classical or typical form rarely or never presents mental or cerebral symptoms characteristic of general paresis. Tabes is a chronic progressive disease, confining its lesions to the posterior spinal nerve ganglion, posterior nerve roots, posterior columns and meninges of the spinal cord, and the cranial nerves, especially the oculomotor and optic. General paresis is a disease comparatively acute, as compared with tabes, running its course in three years, while the former may continue for twenty years or longer. Its lesions are chiefly cerebral, involving the meninges and cerebral neurones, to a slight degree the cranial nerves, as the optic nerve and the superior nucleus of the oculomotor nerves. The spinal lesions are rarely systemic in type, but fall under the head of a diffuse or combined sclerosis of the spinal columns. In 100 cases of general paresis of the optic or cerebral and tabetic type, only one resembled a classical case of tabes. Clinically the symptoms from cases observed in hospital, dispensary and private practice, while approaching each other in a minor degree, essentially differ in intensity in the more marked symptoms. In tabes, the ataxia is much more extreme, and the lightning pains and crises are much more frequent and disabling. The ocular manifestations are much more constant than in general paresis, whether of the cerebral or tabetic type. It is impossible to believe that a disease essentially spinal in its symptomatology and lasting usually at least twenty years can be the same, differing only in the site of the lesion, as a disease limited usually to three years or even in the unusual or extreme cases to ten years.

DISCUSSION

Dr. E. B. Angell, Rochester: The tendency seems to be to disregard the so-called systemic manifestations of degenerative diseases, and ultimately, so far as possible, to include them under one general classification. Clinically, Dr. Fisher is right, and I believe, so far as treatment and recognition of methods of treatment are concerned, that his views are perfectly sound, but it is rather early yet to come to a definite conclusion regarding this matter.

Dr. W. W. Kidder, Oswego: Tabes is a disease of a definite tract and associated clinically with a definite set of functions which are less general than the functions of the parts affected by general paresis; and from the limitation of the original tabetic affection we would naturally expect it to trespass less on the tissues which are involved in paresis than we would expect the paretic affection to trespass on the tissues affected by tabes.

Paralysis of the Upper Extremity Due to Nerve Injury

Dr. N. Jacobson, Syracuse: This paper is based on four cases: Two involve the musculospiral nerve, one is a complication of fracture of the humerus, the other is the result of a lacerated wound in the lower part of the arm. The third patient sustained a fracture of the neck of the scapula, implicating the brachial plexus, and the fourth case was due to a penetrating wound of the neck severing the fifth cervical nerve. In each instance more or less complete paralysis resulted which was improved or entirely cured by surgical operation.

Experience of the Army With Vaccination as a Prophylactic Against Small-Pox

Col. John Van R. Hoff, Medical Corps, U. S. Army: Wars have taught us that the mobilization of military resources promotes the incurrence of small-pox in armies, and all experience has shown that efficient vaccination and revaccination absolutely control it. We of the medical department would be loath to return to conditions under which one-tenth of mankind died of small-pox, and which obtained up to the beginning of the nineteenth century. These conditions ceased with the application of Jenner's discovery and since have been effectually controlled by vaccination. In spite of all these facts, it is asked: Does vaccination really grant immunity from, or lessen the severity of, small-pox? Is not the gradual disappearance of this infection due to isolation and sanitation? The answer is obvious. Of isolation Chapin writes:

> Small-pox is less likely to escape detection than is any other disease. Yet epidemics grow in the face of the most rigid isolation. Unrecognized cases, even in this disease, are so numerous that the isolation of the recognized cases often seems to be a complete failure. The state board of health of Minnesota, realizing this, has had the boldness to advise that no attempt be made to isolate, and that entire reliance be placed on vaccination. It was hoped that this would lead to more complete vaccination. There has been no alarming increase in small-pox in Minnesota.

A century or more ago tuberculosis and small-pox shared almost equally the unenviable reputation of being the most potent causes of mortality in the human race. To-day tuberculosis still maintains its evil reputation, but among enlightened people the mortality from small-pox is negligible. While sanitary standards and practice have measurably advanced since 1797, they have not yet greatly changed the mortality rate for tuberculosis. Why should they have so marvelously affected that for small-pox? They have not, and we are forced to the conclusion that to vaccination and revaccination alone are we indebted for power to control this formerly devastating and deadly infection. The great blessings of vaccination are not bought for nothing, though they are purchased at a very trifling cost.

Diagnosis of Common Tropical Infections

Dr. S. M. Shook, U. S. N.: New York furnishes a large number of cases of the tropical infections, two of the most important of which, malarial fever and amebic dysentery, may be acquired in the state. Diagnoses of the intestinal infections due to animal parasites may be easily made by examination of a fluid stool. Blood examinations for malarial parasites may be readily made with a good polychrome stain which is stable.

Fracture of the Tarsal Bones

Dr. F. H. Albee, New York: Direct trauma to the plantar surface of a foot is likely to cause a fracture of the tarsal bones. In every case diagnosed as flatfoot, whenever a slight injury has occurred, the patient should be examined for fracture of the tarsal bones. This should include an *x*-ray examination. An important feature in treatment of fresh fractures, is to keep patients from weight-bearing, for at least six weeks, and then only with the aid of an arch support for two or three months longer. The best results are obtained in the treatment of fresh tarsal fractures. One of the essential features in the management of these fractures is attention to the changed fatty conditions. This is especially true in the old neglected cases.

Arteriosclerosis or the Cardiovascular Disease

Dr. L. F. Bishop, New York: In treatment of cardiovascular disease the Nauheim methods are of much value, although it is not easy to define the route by which improvement is brought about. By Nauheim method I mean change of mode of life, environment, change of diet, removal from work and worry, carbonated baths and resistance exercises. It has seemed to me that possibly the carbonated baths in some way promote the elimination of indol and its allied products through the skin. The most important thing in treatment of a case depending on intestinal putrefaction is the regulation of food, the use of suitable cathartics, and the encouragement of the germs of lactic acid fermentation by the use of the less fermentable carbohydrates. Recently I have been using milk sugar. Abdominal conditions, such as enteroptosis and gastroptosis must be attended to. Alkaline mineral waters by counteracting the natural acidity of the intestinal tract often do great harm which appears as a most intense auto-intoxication, after a course of such treatment. I saw a patient this winter in whom, following a severe alkaline reduction cure, there was such intense poisoning of the heart muscle from auto-intoxication that chronic fibrillation of the auricle resulted. The question of alcohol and tobacco must be decided according to the individual case.

DISCUSSION

Dr. D. Ayers, Fort Plain: The principal cause of trouble in these cases is intestinal putrefaction, a general condition of auto-intoxication. It is estimated that about 90 per cent. of the general practice in my section of the state is in connection with conditions dependent on auto-intoxication. I have under observation a woman, aged 74, whose blood-pressure was 260 plus; I do not know how much more than that it was because the scale does not run any higher. She is dizzy most of the time. She has been very toxic for years, and has been constipated ever since she can remember. She has always been a good eater and is jaundiced most of the time. Occasionally she has hemorrhage from the nose. The retinal vessels are very much engorged and varicosities appear. Recent treatment reduced the blood-pressure below the point mentioned, but it is still very high.

Dr. E. B. Angell, Rochester: I am not yet ready to say whether it is intestinal putrefaction or inefficient elimination of the nitrogen material through the kidney that is the cause of most of the symptoms in these cases. However, there is no doubt but that the over-ingestion of meat, or the over-ingestion of nitrogenous food, has more to do with cardiovascular disease than any other one thing. We must bear in mind that meat tends to putrefactive conditions in the intestinal tract.

Dr. J. M. Swan, Watkins: Arteriosclerosis is not an inflammation, but a degenerative change dependent on a great many varying causes, the intemperate use of alcohol and tobacco being among them. But a great many people who have never used alcohol and tobacco, who have had the acute infectious diseases, and who have indulged in the overeating of proteid food as well as carbohydrate foods, have improper elimination of the end-products of these substances on account of insufficient exercise. The disease is a general one, but its symptoms may be manifested in one of three main places: in the kidneys, producing nephritis; in the heart muscle, producing fibromyocarditis, and in the brain, producing the various brain symptoms of arteriosclerosis.

Dr. H. Schoonmaker, Clifton Springs: When we resort to the so-called starvation treatment, that is, putting these patients to bed and keeping them on a milk diet, cleaning the bowels out and giving them rest and sufficient water to drink, it is surprising how much better they get. It has been my observation that the carbon dioxid bath, the so-called Nauheim bath, unless it is materially modified, does not do so well for the patient as the sweating bath.

Dr. F. D. Reese, Cortland: Patients with arteriosclerosis should be put on a restricted diet. I do not care so much what a man eats as I do the amount he consumes. If you can get the confidence of a patient, you will gain one point, then tell him to fast every other day. This seems harsh treatment, but it is the most effectual treatment in arteriosclerosis or high blood-pressure of anything I have prescribed.

(To be continued)

Medical Education and State Boards of Registration

COMING EXAMINATIONS

Kentucky: The Armory, Louisville, May 31. Sec., Dr. J. N. McCormack, Bowling Green.

Louisiana: Regular, New Orleans, May 18-20. Sec., Dr. A. B. Brown, 108 Baronne St.

Nebraska: State House, Senate Chamber, Lincoln, May 24. Sec., Dr. E. Arthur Carr, 141 S. 12th Street.

New York: May 23-26 and June 27-30. Mr. Harlan H. Horner, Chief of Examinations Division, Department of Education, Albany.

Wisconsin: Milwaukee, May 24-26. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

New Board in Oklahoma

The Oklahoma State Board of Medical Examiners, as at present constituted, consists of Dr. F. B. Fite, Muskogee, president; Dr. R. E. Sawyer, Durant, vice-president; Dr. F. A. Englehart, Oklahoma City, treasurer; Dr. John W. Duke, Guthrie, secretary; Dr. M. Gray, Mountain View; Dr. Leroy Long, McAlester; Dr. J. O. Wharton, Duncan; Dr. W. L. Bonnell, Chickasha, and Dr. Philip Herod, Alva. The first examination under the new board was held April 13, when thirty-two applicants were examined.

Iowa January Reciprocity Report

Dr. Guilford H. Sumner, secretary of the Iowa State Board of Medical Examiners, reports that at the meeting held at Des Moines, January 24, 1911, twenty candidates were licensed through reciprocity. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Rush Medical College	(1910)	Illinois
	(1896)	Nebraska
Northwestern University Medical School	(1906) (1907)	Illinois
	(1898)	Wisconsin
Coll. of Med. and Surg., Physio-Medical, Chicago	(1886)	Wisconsin
College of Physicians and Surgeons, Chicago	(1906)	Illinois
Hahnemann Med. College and Hospital, Chicago	(1909)	Illinois
Chicago College of Medicine and Surgery	(1909)	Illinois
State University of Iowa, College of Medicine	(1908)	Illinois
University of Louisville	(1910)	Illinois
College of Physicians and Surgeons, Baltimore	(1904)	Illinois
St. Louis College of Physicians and Surgeons	(1909)	Kansas
American Medical College, St. Louis	(1903)	Missouri
St. Louis University	(1906)	Missouri
University Medical College, Kansas City	(1910)	Missouri
Starling-Ohio Medical College	(1909)	Ohio
Jefferson Medical College	(1909)	Delaware
Woman's Medical College of Pennsylvania	(1907)	New Jersey
Medico-Chirurgical College of Philadelphia	(1898)	New Jersey

Utah April Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, April 3-4, 1911. The number of subjects examined in was 21; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 5, of whom 3 passed, including 1 osteopath, and 2 failed. Five candidates were licensed through reciprocity. The following colleges were represented:

College	Year Grad.	Per Cent.
PASSED		
Georgetown University	(1908)*	
Jefferson Medical College	(1910)*	
FAILED		
Gross Medical College	(1895)	56
Keokuk Medical College, Coll. of P. and S.	(1905)	73

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with

License and Proof Required to Recover for Services—Evidence Against Charge of Malpractice—Wealth of Patient Cannot Be Shown to Justify Fee

The Court of Civil Appeals of Texas reverses, on the appeal of Swift vs. Kelly (133 S. W. R. 901), a judgment obtained by the latter party, a physician who brought the action to recover for professional services. The court says that the defendant insisted that the lower court erred in overruling his general demurrer to the plaintiff's petition, in that it failed to show that the plaintiff was authorized by law to practice as a physician and surgeon and to maintain a suit to collect for such professional services. That contention is sustained.

By the Texas statute, as amended by the legislature in 1901, boards of medical examiners were established, a license from which was required as a condition precedent to the right to practice medicine and surgery in the state; and one article provides that any person who shall practice medicine, surgery or midwifery in the state in violation of the statute shall be fined or imprisoned, and it shall not be lawful for him or her to recover by action, suit, motion or warrant, any compensation for such services. It is well settled that a physician practicing in Texas without the license required by the statutes cannot recover for his services. A compliance with the requirements of the law regulating the practice of medicine and surgery having been made a condition precedent to the right to so practice, it is necessary for one suing to recover for such services to allege and prove such compliance, and a failure to so allege in the petition is fatal on general demurrer thereto.

It is also well established that, in the absence of proof to the contrary, it will be presumed that the laws of other states are the same as the laws of Texas on the same subject. The plaintiff failed to allege in what state his services were performed. If they were performed in Texas, then the Texas statutes would apply as a matter of course. If performed in some other state, then the presumption would obtain that the same statutes had been there enacted and were in force. It was not sufficient that he alleged in his petition that he resided in a certain other state, was a physician and surgeon, practicing his profession in such state, and was a professor in a university in such state.

Then, over the defendant's objection, the plaintiff was permitted to introduce in evidence the defendant's promissory note in the plaintiff's favor for $500 of the amounts sued for, and also letters and telegrams from the defendant to the plaintiff requesting an extension of time for its payment. The ground of the defendant's objection was that, as the suit was to recover on a promise to pay the reasonable value of the services, evidence showing a contract to pay a specific sum was irrelevant and incompetent. The evidence was not admissible to prove the value of the services rendered by the plaintiff. But, among other defenses, the defendant alleged unskilful and negligent treatment of him by the plaintiff, and offered evidence in support thereof. As against that defense, the court thinks the evidence to which the objection was made was admissible as the same would be in the nature of an admission at variance with the defendant's plea of unskilful and negligent treatment.

Lastly, this court is of the opinion that the lower court erred in permitting the plaintiff to show the reasonable value of his services by proof that the defendant was wealthy, coupled with further proof of a custom among physicians to graduate their charges according to the financial condition of the patient, and to charge a wealthy patient a higher fee by reason of his superior ability to pay. The suit was to recover the reasonable value of professional services rendered by the plaintiff. In 30 Cyc. 1600, it is stated that there is a conflict in the authorities on this question, and the announcement seems borne out by the decisions there cited. In Robinson vs. Campbell, 47 Iowa, 625, one of the cases cited, it was held that such testimony is not admissible, and the reasoning there advanced this court thinks is sound. Certainly no court would hold that the value of ordinary labor could be determined by such a test, and on principle this court can see no distinction between such a claim and one of the character now under discussion. If the recovery sought in this suit for professional services had been on an alleged implied contract by the plaintiff to pay such fees as are customarily charged for the same character of services performed for a patient of like financial ability to pay a fee therefor, then a different question would be presented, but, as the same is foreign to the record, the court foregoes a discussion of it.

Book Notices

Manual of Diseases of Women. By W. E. Fothergill, M.D., Assistant Gynecologic Surgeon Royal Infirmary, and the St. Mary's Hospital. Cloth. Price, $3 net. Pp. 433, with 144 illustrations. New York: William Wood & Co., 1910.

Certain parts of this compendium will be found useful for the general practitioner, more especially the student and the nurse. The anatomy and embryology are handled exceptionally well. It is to be regretted that, in the chapter devoted to physical examination, the author has practically ignored asepsis. He has not even remotely suggested the use of rubber gloves, the sterilization of hands and instruments, or in any way recognized the need of protecting the examining physician, or emphasized the danger of infecting the patient with dirty technic. Several methods mentioned of preparation of the field of operation could well be relegated to the antiquities of surgery. In discussing the treatment of infections, the author warns against washing out the protective lactic acid bacilli in the vaginal secretions with the vaginal douche; yet further on, in contradiction to these views, he recommends the treatment of acute pelvic infections with the hot douche. Although the author intimates his belief in the radical removal of the glands and perimetric tissue in uterine carcinoma, he fails to recommend specifically or in any way to describe the radical Wertheim operative procedure.

An Introduction to Surgery. By Rutherford Morison, M.A., M.B., F.R.C.S., Edin. and Eng., Professor of Surgery, University of Durham. Cloth. Price, $2.50 net. Pp. 162, with 151 illustrations. New York: William Wood & Co., 1911.

As its title indicates, this work is intended as a preliminary course for students in the study of general surgery. The author states in the preface that it is his aim to direct the student toward the main principles of diagnosis and treatment, thereby simplifying and making rational the treatment of the various surgical affections. In some particulars this object has been admirably realized. The chapters dealing with inflammation and sepsis are good, treating the subject in a practical and lucid manner. The same may be said of the treatment of the surgical diseases of the hollow viscera, the diagnosis of syphilis, tuberculosis and malignant disease, and also of the chapter on ulcers and gangrene.

On the other hand, it appears that comparatively too much space, which might better have been given to some subjects treated briefly, has been allotted to others of minor importance. Also, some subjects have been introduced which today are not ordinarily included in a course of general surgery. A little more accuracy in the definition of certain terms might have been exercised and the use of some obsolescent terms avoided.

The work is profusely illustrated with well-executed sketches, diagrams and photographs, which add not a little to its value as a students' text-book.

The Influence of Storage and Various Preservatives on the Dissolved Oxygen in Waters. By Dr. Arthur Lederer. Paper. Pp. 14. Sewage Disposal Investigations, the Sanitary District of Chicago, 1910.

The conclusion is drawn from a considerable number of chemical analyses that the addition of 1 c.c. per 8 ounces will preserve the content of dissolved oxygen in both unpolluted and polluted water for sufficient length of time for samples to be transported to the laboratory for examination. The percentage reduction of dissolved oxygen in stored samples is believed to constitute a "fair index of appreciable pollution."

4 and 5. Abstracted in The Journal, Nov. 26, 1910, p. 1920.

6. Abstracted in The Journal, Dec. 3, 1910, p. 2005.

7. **Fracture of the Long Bones.**—Crook reports four recent cases of fracture of both tibia and fibula in which he operated, and in all of which he secured good results, a result which, he says, could not have been obtained without operation.

8. **Painful Halux Valgus.**—Cole reports one case in which he used Mayo's method—resection of the head of the first metatarsus, removal of exostosis; restoration of joint by inserting flap of synovial tissue between stump of metatarsus and base of first phalanx. The result was perfect.

9. **Occurrence of Intestinal Parasitic Infections.**—Among 220 white men in the Florida Hospital for the Insane, Greene found ninety-two cases of uncinariasis, or a percentage of nearly 42. The 187 women examined showed a total of 87 cases of uncinariasis, or a percentage of nearly 47; 4 per cent. more women than men showed uncinariasis in this series. These examinations show for the total number of cases in the white departments of the hospital a percentage of nearly 44. Forty-two patients not showing hookworm infection, or a percentage of over 10, were infected with other forms of intestinal parasites, namely, trichocephalus trichiuris, oxyuris vermicularis and ascaris lumbricoides. Taking these other forms of intestinal parasites into consideration in the computation of the percentages would reveal the surprising result, that among the 407 persons examined, there were found 221 cases of intestinal worm infection, or a percentage of 54. Round worms were found associated with hookworms in two cases, one of these being in each sex. *Trichocephalus dispar* infection was noted with uncinariasis in twenty-six cases, sixteen among the women and ten among the men. Triple infection was noted in three patients, all men, the parasites present being *Uncinaria americana, Ascaris lumbricoides* and *trichocephalus trichiuris*. Greene advocates that every county and municipality appoint a physician for special work along this line, and that he should; under the direction of the State health officer, make at frequent intervals an examination of the feces of every individual within the limits of his prescribed area.

19. **Pyelocystitis.**—Six cases are reported by Broderick, five of them occurring in females, in each of which there was a preceding history of ileocolitis within six months of the urinary infection. In only one of the cases was there a rigor; it lasted twenty minutes. There was slight vulvitis in two cases. Broderick adopted Thompson's method of treatment. It consists in the administration of potassium citrate (from 48 to 60 gr., increasing to from 120 to 180 gr. in the twenty-four hours). There will be noticed a rather marked change as the urine becomes alkaline. Hexamethylenamin, in doses of from 3 to 5 grains, is frequently administered. Broderick combines the two methods, giving the citrate in increasing doses, every two hours, until the urine is alkaline. He then gives hexamethylenamin, in doses of from 3 to 5 grains, three times daily. The remaining treatment is that of any infection of the urinary tract.

21. **Teaching Medicine Aright.**—The experiences and the sober thought of thirty-three years—thirty of them (from 25 to 55 years of age) spent as dean or professor or president in three universities, each with a medical department, are laid bare by Jesse. He says that people need not have much knowledge of anatomy or physiology to understand that to learn medicine aright one must have considerable previous training; nor is it necessary to know the length of the alimentary canal to see that professors who spend most of their time in private practice, devoting only spare time to teaching, cannot give the best instruction. If any professional school aims at excellence, it should admit no students that have not had at least four years of good high school training and two years more in a college. In preparation for medicine these two years should be devoted to general chemistry, physics, zoology, botany, French, German and English. Moreover, no school can now give good instruction in medicine unless it has a library, a museum and a number of laboratories, all well-equipped, and each occupying several rooms. How many laboratories are indispensable? The most modest estimate would surely include (1) anatomy, (2) physiology, (3) physiologic chemistry, (4) bacteriology and pathology, (5) pharmacology and materia medica. The equipment of these laboratories is expensive and each must be in charge of a professor who gives all his time to teaching and research. Moreover, he must have one or more paid assistants, according to the number of students. Large income from endowments or other sources is absolutely necessary; fees alone will not pay the bills. Work in these laboratories should occupy the whole time of every student in the first eighteen months of his course.

The last two years (eighteen months) of the four years' course (thirty-six months) are given, in good institutions, to preventive and curative medicine—clinics, so-called. For this instruction there must be a sufficient hospital, a dispensary, a number of laboratories, clinical teachers and, in Jesse's opinion, much revision of modern methods in America. As to whether the clinical teachers should have a private practice, Jesse states that no man can meet the demands of a large private practice and at the same time give the best instruction in any professional school. Success in practicing a profession comes rather late in life for a man to pick up skill in teaching, and attainment in the technic of an art does not of itself bring ability to instruct others therein. Every medical school should have its principal chairs for clinics filled by men who devote their entire time to teaching and research—men who are not for hire by individuals. They should receive adequate salaries, say from $3,000 to $7,500 a year, according to the value of the man and the costliness of the living in the locality. They should practice in the college hospital of course, but the fees, if there be any, should go to the institution. The hospital, furthermore, should be absolutely under the control of the college. Jesse considers that at least these five cairs, filled in this way, are necessary: (1) surgery, (2) theory and practice of medicine, (3) gynecology, (4) therapeutics and (5) eye, ear, nose and throat surgery.

Revision is needed also in the management of college hospitals. They should accept only, or chiefly, at least, carefully selected patients useful for clinic or research. Only in this way can the best material be obtained for illustration in teaching and for discovery through research. Another false notion, in Jesse's opinion, is that the larger the number of cases the better the clinics, even for undergraduates. Vast clinics and various cases are not necessary for the undergraduate, or even good for him; but rather clinics graded and selected. The undergraduate might spend his summer vacations in larger hospitals, as young engineers spend theirs in field or mine or factory. Moreover, in every state university, at least, the hospital ought to be practically free. In this way it can be made far better, both for teaching and for research.

Another fundamental error found everywhere, he says, is that good clinics are obtainable only in large cities. This notion is far wide of the truth. A hospital of 150 beds, by carefully selecting its patients, can give the best instruction for undergraduates in reasonable number. Every state university in a small town, with a hospital of 150 beds, by accepting without charge cases curable, or incurable, but interesting for illustration or research or both, can have all its beds regularly occupied. It has only to support one good traveling lecturer on hygiene—personal, household and municipal—and to employ one collector of cases in every large city of the state. The collectors (who would not give all their time to this work) might be obtained for $500 a piece annually, and the lecturer for $3,000 or $3,500 with (say) $1,500 more for traveling expenses—about $5,000 a year. What would be the results? The lectures, all free, would illuminate the people and thus promote public health; the physicians of every locality visited might be brought into hearty cooperation with the state university and thus serve as collectors of patients. Jesse points out that state universities, nearly all in small towns, have a rich opportunity through their medical departments, to raise to right notions on this subject the people about them, if only they will go boldly forward toward traveling lecturers, free campus hospitals, selected clinics, investigations into the causes of diseases and right ways of preventing and of ejecting them. Their chief aim should be preventive medicine.

31. Hospital and the Young Physician.—Speaking of the value of hospital training to the recent graduate, Darnall says that it brings him in intimate contact with the best of the profession, enabling him to be started along right paths. The ability to apply practically what he has learned is developed within him, besides a systematic way of doing things, and he learns that not all of medical lore is to be found in printed books or prosy lectures; he sees something of the personal relation between physician and patient, which, sociologically, is a most important thing. If afterward he acquires a position in some hospital it will stimulate him to put forth his best efforts in scientific attainment. If he has ability along any certain line it will give him the opportunity to demonstrate it. The hospital becomes for the young man a finishing school in which the mind is trained to accurate methods and correct reasoning. The daily habit of thoroughness, diagnostic accuracy and the ability to go straight to the point, laying aside the non-essential and unimportant, after a time become habitual. His work is all charted, and is an open book. He must submit to the criticism not only of men of older and richer experience, but also of the younger men with newer methods and even the interns themselves fresh from the laboratories and the schools. It behooves him, therefore, that his work should be of the highest grade and the pride of his reputation cannot afford that it be otherwise. His position demands that he should stand for all that is best and most scientific in medicine. This critical fire to which he is subjected, however, brings out whatever qualities he has and stimulates him to give the best that is within him. The greatest good the hospital does in any community is not so much what it does for the individual as the good it does in sending out men trained to the scientific habit of mind, and whose influence and authority as leaders is reflected in the general diffusion of sanitary knowledge in the community.

33. Hospital's Recompense to the Staff.—In Davis' opinion, the indirect compensation to a doctor on a hospital staff has been greatly exaggerated. If the same amount of time spent in hospital work were spent in study and investigation, and attention to one's office and practice, he thinks that much more benefit would ensue. He says that it is only the small hospitals and some church institutions that do not now pay their physicians for attending patients who occupy private rooms. Of course, the amount of these fees varies much, but it is becoming more and more a recognized principle that the physician laborer is worthy of his hire.

Davis asks whether a hospital patient who is able to pay should not have the choice of his medical attendant, and, also, should hospitals receiving state aid distribute their favors to only a few physicians, or should all have an equal chance? He believes that the answer to these two questions will lead, sooner or later, to the establishing of two kinds of hospitals, the first, a purely eleemosynary institution where none will be treated except those who are unable to pay, and its staff will consist of men who are paid a just salary by the management for their services, in the same manner as hospitals for the insane pay their physicians now. The other kind will be, as it were, invalid hotels, open only to those who will pay according to their accommodations. Such an institution would have no staff, but would be at the service of all reputable physicians. The medical attendants would arrange for their compensation with their patients, just as they would do in private practice. The hospital would make such charges as the manager should see fit for rooms, operating rooms, nurses, etc. Such an institution could restrict its patients to special diseases, or have different departments. It could have private operating rooms to lease to special surgeons. It would supply nurses and such conveniences as a hospital should offer, but private nurses could be employed by any physician. If these two institutions should be housed in one building, the method of paying the medical men would remain exactly the same as if they were in separate buildings. This might be the type for so-called church hospitals. It would prevent hospitals from sailing under the banner of charity, when they are too often simply money-making institutions. It certainly would recompense medical attendants in hospitals, in a much more equitable way than at present. It would also keep from unduly increasing the number and capacity of hospitals and establish them more firmly on a business basis. In many cities the hospital accommodations are very much larger than are required and the expense of maintenance is urged as a reason for not giving proper recompense to the staff.

34. Economic Influence of Hospital Administration on the Medical Profession.—The points which Vander Veer brings out are summarized as follows:

1. Contributions for the construction of the general hospital to be received from those who are disposed to give for such a charitable purpose, thus becoming a partner with the physician in caring for patients who cannot pay for services in their own homes.

2. The care of such contributions, and the organization of the hospital to rest in a board of governors, or trustees, there being a representation on said board from the medical staff of the hospital, the object of this being a close community of interest, at their meetings, and for the discussion of subjects in which they are mutually interested.

3. Appointments on the medical and surgical staff to be made on the recommendation of the staff proper, to be confirmed or rejected by the board of governors.

4. The fee for care of patients in the semiprivate wards or private rooms to be left entirely with the attending physician or surgeon in like manner as though the attention were given in their own homes, hotels or boarding-houses.

5. The semiprivate wards, too, offer an opportunity for the younger members of the medical profession to care for a larger number of patients, when brought to the institution and who are unable to pay for services, than they could elsewhere.

6. Encouragement for every patient who can do so to pay for his board in the public or semiprivate wards, knowing they will receive the attention of the staff of the hospital, or, as is the case in many instances, of the physician or surgeon whom they themselves may select.

7. An opportunity for the public to give to the general hospital such sums as they may feel disposed for making up the deficit that so often occurs in the care of patients who pay all they can and yet are not able to meet the full charge for their expenses. In this manner the self-respect of the patient and friends is maintained, although they still require a little additional aid.

8. A most excellent method for the city to care for its sick and injured and a great protection to the taxpayers.

9. The endowment fund offers an opportunity for the benevolently inclined to place such gifts as he or she may feel disposed to give under the control of an institution that is to be lasting, and where only the interest is to be employed for the annual expenses. Few institutions in this country have endowments sufficiently large whereby the interest will maintain all expenses, and where such do exist only strictly charity cases should be admitted.

35. **Hospitals and Their Respective Communities.**—Eisenberg points out that the influence of a hospital on its surrounding community is beneficial in the broadest sense.

1. The presence of a hospital in any community furnishes prompt attention in all cases of accident or disease, especially to grave and apparently fatal ones, that might otherwise be jeopardized by transmission to some more remote point.

2. The nearness of a hospital arouses more interest and sympathy in its administration and for those cared for in its wards. Especially is this the case when those on the board of management are *selected from the citizens of the immediate community.*

3. The proximity of a hospital with its continual needs of assistance appeals to the benevolent heart of a community and stimulates not only giving but benevolent work for its support.

4. The location of a hospital in any community wherein its presence has created benevolent interest accomplishes much toward effacing the hard-and-fast social and sectarian lines by unifying sentiment in one common purpose.

5. In all populous centers wherein a sufficient number of physicians and surgeons are found willing to support a hospital by their gratuitous services such association with the institution is highly beneficial to that community, because of a better feeling that is thus promoted among the medical staff of the institution.

6. The medical staff of such hospital, because of the accumulation of clinical material of great value, is being constantly trained and educated for better work in the homes of their private patients and, therefore, indirectly the community itself is benefited.

7. The great advance within the past twenty-five years in methods of prevention of disease and of the necessity of more scientific care of the sick and injured has rendered a school for training nurses an essential adjunct to a well managed hospital, therefore such institution, in preparing and furnishing trained nurses for service among the sick in their homes, confers a great benefit on a community.

40. **Cystoscopic Findings in Tabes Dorsalis.**—Lateral trabeculæ formation, rigidity of the ureteral orifices and hypertrophy of the interureteric ligament, according to Koll, compose the three important points which should lead to a further investigation directed toward changes in the spinal cord. Symptoms referable to the urinary tract should call for a cystoscopic examination. The bladder picture which is found, *in toto,* differs from any other seen through the cystoscope. The most striking changes are found at the ureteral orifices which, instead of showing the rhythmical, uniform, sphincter-like action with each extrusion, allow the urine to flow out without any evidence of a muscular contraction. To this condition, which he has been unable to find described anywhere, Koll has given the name ureteral-orifice rigidity. In some of the cases this rigidity may not be complete, and thus closely resemble the rigidity of the sluggishly acting pupil. There is a more or less marked hypertrophy of the interureteric ligament manifested by increased vascularization and distention of the arteries; the ridge between the two orifices is distinctly higher and stands out well above the remainder of the mucosa of the bas fond.

A third point to make up the diagnostic triad is the typical trabeculization, or the *balken* of the Germans. This differs from the picture given by an overworked bladder due to obstruction by showing the trabeculæ only on the lateral walls of the bas fond, and apparently continuous with the interureteric ligament at either end. The trabeculæ, too, are finer and more nearly resemble the papillary muscles of the heart. In no case in the class under consideration did Koll see any trabeculæ in the median line, in the fundus or extending high up on the lateral vesical walls.

56. **Chromo-Ureteroscopy.**—Conclusions as to the functional sufficiency or insufficiency of a kidney, based merely on the onset of the elimination of indigocarmin, Thomas says, may be erroneous. The intensity of the color reaction must also receive serious consideration. Therefore, the first law of the chromo-ureteroscopist is to obtain and maintain an absolutely clear fluid content in the bladder. The second law is to have a sufficiently brilliant illumination. If these two conditions are not secured, he will frequently fail to observe the earliest

onset of the elimination of the indigo, particularly if it is a light blue coloration and merely oozes from the ureteral orifices into the bladder, instead of exhibiting the normal spurt. The first law can be best fulfilled by prolonged irrigation, if indicated, and the employment of an evacuation cystoscope, so that the bladder may be emptied quickly and refilled when necessary. The second law is not so difficult, requiring simply care in the selection of a good cystoscope and the testing of the lamp before introduction into the bladder.

Chromo-ureteroscopy based on the employment of indigocarmin is regarded by Thomas as the most valuable single test for renal sufficiency or insufficiency. The test is said to be particularly applicable for surgical affections of the kidneys and ureters and almost invariably suffices to establish the diagnosis, if, when the indication arises, it be supplemented by ureteral catheterization. It is of no value in movable kidney in the absence of a ureteral kink or hydronephrosis, pyelitis, early tuberculous and certain other forms of nephritis and small tumors not involving a majority of the parenchyma. It is of value in the differential diagnosis of hemorrhagic and chronic interstitial nephritis from other types of the disease. Supplemented by ureteral catheterization, and the Roentgen ray, it will serve to diagnose practically every case of renal and ureteral calculus. In hydronephrosis, pyonephrosis, pyelonephritis and chronic tuberculosis of the kidney involving approximately one-third of the parenchyma, chromo-ureteroscopy is of exceptional merit. In simple hypertrophy or carcinoma of the prostate, causing chronic retention of the urine, the indigocarmin test promises to be of value in the differentiation of operable and non-operable cases.

Chromo-ureteroscopy is also of great value in the differential diagnosis of obscure abdominal tumors, also in facilitating difficult ureteral catheterization. Indigocarmin is eliminated from normal kidneys as a dark blue in from 4½ to 20 minutes; as a light blue, not later than 15 minutes. In 86.7 per cent. of normal kidneys it appears either as dark or light blue in from 4½ to 15 minutes. If the indigo does not appear at the expiration of from 15 to 20 minutes, it is evidence of serious insufficiency of the renal function. If the elimination of the dye does not occur at all, the kidney or ureter is gravely diseased. The intensity of the color reaction (dark blue or light blue) depends on the concentration of the urine and the individual secretory power of the organ. A surgically diseased kidney eliminates the dye less intensely than its normal sister organ, or not at all. The test is very simple and by alternate observation of the two ureteral orifices, differences between the two kidneys are readily and speedily noted.

61. **Ventrosuspension in Displacement of Uterus.**—In Vineberg's method, four sutures are used to suspend the uterus by means of the tubes, two on either side. One suture passes around the tube 4 cm. from the uterus, the other at its insertion into the uterus. The sutures pass through the rectus muscle and fascia and are tied on the fascia. The wound is closed in the usual manner.

62. **The Closure of the Abdominal Incision.**—Overlapping of the cut edges of the rectus fascia is the end aimed at by Tracy. The peritoneum is sutured with catgut, and the same suture is used to whip together the muscle. On the right side of the wound, the fascia is separated back from the muscle, for from 1 to 3 cm.; likewise on the left side. Tension sutures are then introduced through the skin about 3 cm. from the edge of the wound, passing through the fat and the fascia about 1 cm. from the edge, then in and out through the fascia on the left side from 1 cm. to 3 cm. from the edge, and back through the fascia on the right side, then out through the fat and skin on the left side. The sutures are placed from 4 to 5 cm. apart. Next the edge of the overlapping fascia is whipped down with chromic catgut, and the skin sutured with a buttonhole stitch. If the ends of the tension sutures are drawn taut, the fascia will overlap, and the whipping down of the edge will be facilitated. Gauze saturated with 70 per cent. alcohol is placed over the wound and the tension sutures are tied over the gauze. The tension sutures are removed in from ten to fourteen days.

In patients in whom there is a wide separation of the recti muscles and marked relaxation of the abdominal wall, the fascia is overlapped to the extent the recti muscles are separated. In cases of marked relaxation, the recti muscles are dissected out and sutured from an inch above the umbilicus to the pubic bone. It is not considered advisable to constrict the upper abdomen as such a procedure has a tendency to increase the visceroptosis, which is usually present. If the peritoneal cavity is opened when separating tissues about the umbilicus, the peritoneum is sutured transversely as there is less tension and the approximation is better. After the recti muscles are sutured, the edge of the fascia on the left side, which is slid under the fascia on the right side, to the extent the muscles were retracted, is anchored with mattress sutures of chromic gut, and the edge of the fascia from the right side is sutured in the usual way. In order to make a good approximation and to avoid any infolding of the fascia at the upper end of the wound, this fascia on the right side is cut transversely, and the vertical incision carried slightly upward, and to the left. The upper segment (above the transverse cut) is then slid under and the lower segment over the fascia on the left side. The free edge of the fascia is then sutured. When it is necessary to leave one end of the wound open for drainage, the same technic is employed, except that no gauze is interposed between the skin and the tension sutures. By employing this method the separation of the fascia in the part of the wound not closed is less, and the abdominal wall is stronger than if closed by through-and-through sutures; dead spaces are eliminated; the fascia is overlapped and approximated accurately and remains overlapped even if the catgut is absorbed in a few days. No dead space is left in the fat and the necessity of suturing this layer is eliminated. In cases in which there is an excess of serum or slight oozing in the skin or fat immediately after the operation, the pressure from the tension sutures tied over the gauze will force the serum or blood through the skin incision, where it will be taken up by the gauze. If primary union of the wound takes place, it is practically impossible for a hernia to follow, and if the technic is proper, suppuration will seldom result.

75 *A Modified Vaccine Therapy Based on the Theory of Multiple Infections and Quantitative Reaction. A. F. Schafer, Bakersfield, Cal.

75. **A Modified Vaccine Therapy.**—The vaccines used by Schafer are neither "bacterial vaccines" nor "serums" as ordinarily understood, but are solutions in sterile water (to which approximately 0.5 per cent. phenol has been added) of the soluble substances generated by the organisms when grown in suitable culture media. The product is sterile and contains neither live nor dead bacteria, all organisms having been removed by filtration through porcelain. The "mixed-infection vaccine," which is used in the treatment of infections of any character whatever (except where the diagnosis has been clearly established and the predominating causative organism is known) is made from a large variety of pathogenic bacteria. This is a polyvalent preparation, since the organisms are not confined to any one strain of a given species. Two

hundred patients ill with pneumonia have been treated with the special pneumococcus vaccine. A series of fifty-six patients with lobar pneumonia treated with the special vaccine without a single death included two infants, seven children whose ages varied from two to eleven years, eight adults who were chronic alcoholics (three of whom had delirium tremens), sixteen complicated with measles, three with peritonitis, three with virulent peripheral lesions; two obstetric patients; five with typhoid infection, six with double lobar pneumonia, and fourteen individuals over 60 years of age, one being 92. One hundred and fifty patients with typhoid were treated, and of these four died, two from perforation and one from hemorrhage. The average time from the treatment to recovery was ten days. Good results were obtained in several cases of acute articular rheumatism. Considerable improvement followed the use of tuberculosis vaccine in a series of ten cases exhibiting a variety of tuberculous lesions. In gonorrheal infections the results were such that definite conclusions are unwarrantable.

87 *Treatment of Typhoid with Special Reference to the Use of Hydrochloric Acid. A. McAlister, Camden, N. J.

87. **Hydrochloric Acid in Typhoid.**—It is McAlister's uniform practice to use the acid in every case just as soon as the alimentary tract has been well prepared for systematic feeding by the use of eliminatives, preferably broken doses of calomel followed by a saline or castor oil. He gives the acid well diluted, in doses ranging from 2 to 15 minims, according to age and the needs of the individual case, three or four times a day. Pepsin may be added when it seems especially indicated, particularly in the very young or very delicate, and the mixture may be made especially palatable by giving it in the form of an artificial gastric juice. This McAlister regards as being the ideal mixture for pediatric use. The treatment calls for water, both for pleasant administration of the acid and to satisfy the thirst it tends to excite. This in itself is a noteworthy advantage in the treatment of this particular febrile condition in which patients almost never, without special and constant urging, imbibe enough water. But the greater value of the acid lies in its effect on gastric digestion and the tone of the digestive processes generally. He urges more extensive use of this treatment.

99. **Serotherapy of Pneumonia in Infants.**—About a year ago Sill became interested in a polyvalent composite serum obtained from diphtheria-immune horses for use in pneumonia. The serum was injected subcutaneously, in doses of 10 c.c., at varying intervals, depending on the symptoms and the effect it had on the patient. In some cases one injection seemed to be sufficient to relieve the symptoms and check the disease, while in others repeated injections of 10 c.c. were given every day or at longer intervals, although not always with favorable results. Sill thinks that, perhaps, in these latter cases, if larger doses had been given or the serum had been injected at more frequent intervals, it might have made a difference and given a more immediately favorable result. In all, twelve patients were treated by means of the serum, eight males and four females. Their ages ranged from 5 months to 3 years; all but two were under 2 years, and three of these were under 1 year. There were three cases of lobar pneumonia and nine cases of bronchopneumonia. Two patients died, one of empyema and one of extensive double pneumonia, marasmus and cardiac failure (mortality 16.6 per cent.). Two other patients besides those who died were not helped by the serum, but the other eight were all more or less improved and in some of the pacients the effect of the serum seemed marked. Those patients who received the serum early in the disease seemed to be most benefited by its use.

100. **Treatment of Diabetes Mellitus.**—Carter calls attention to the fact that the only real success comes through a proper dietary regulation, and as the chief symptom, glycosuria, is dependent on the incomplete metabolism of carbohydrates, any plan for efficient treatment must center about the proper training of the organism to reacquire, to some extent, the lost power of properly burning the carbohydrates. In other words, it is the partial re-education of the individual to the proper digestion of starch and the sugars, a power which has been lost through some defect in the physical economy of the secretions, notably the pancreatic internal secretion.

101. **Spontaneous Disappearance of Malignant Growths.**—Attention is directed by Gleitsman to the fact that this phenomenon does occur, and he urges that the subject be made one of more intensive study.

104. **Venous Thrombosis.**—The chief points to which attention is called by Conner are the following: Pulmonary symptoms are, not infrequently, the first indication of a beginning venous thrombosis, preceding often by several days the local evidences of such thrombosis. Such symptoms are the result of the lodgment in branches of the pulmonary artery of emboli derived from the newly formed, friable thrombi in the peripheral veins. These early pulmonary emboli are usually of small size and the symptoms arising from them are frequently slight and transient. The symptoms of pulmonary embolism and infarction by no means always correspond to the classical descriptions of them. One or more of the cardinal symptoms are frequently lacking. This is especially true of hemoptysis, which is often absent entirely, and at other times appears only several days after the onset of the other symptoms. The physical signs are usually either those of a more or less extensive plastic pleurisy or of a small area of

pneumonic consolidation which lasts only for three or four days. Venous phlebitis and thrombosis, in very many instances, begins in the small peripheral veins, especially in those of the calf, where it may exist for some days before the symptoms of thrombosis of the large veins appear. The chances of pulmonary embolism seem to be much greater at the beginning of a venous thrombosis than later on in its course. Some of the obscure chills in typhoid, Conner says, are related to the lodgment of pulmonary emboli. He cites nine cases to illustrate the points made by him.

106. **Case of Multiple Myeloma.**—The disease that carried off Austin's patient was a myeloma, that is to say, a tumor of the bone-marrow, whose point of departure was in the substance of the twelfth dorsal vertebra, which collapsed through total disappearance of its bony substance. There were metastatic nuclei in the neighboring vertebræ, and in the ribs. This myeloma was characterized by the predominance of lymphocytes. The lymphnodes had undergone a form of atrophy, and a radical change of structure such as is sometimes observed in anemia. There were evident traces of old and healed tuberculosis of the lungs. There were likewise traces of former inflammation of the pleuræ and peritoneum, which was no doubt also tuberculous. It was to this inflammation that the renal lesions appeared to have been due. The points in this case that seem to be of particular interest are the following: A long period of preliminary silence, which probably covered the entire winter. The period of increasing pains, lasting three months, ending in a big crisis, and followed by six months of uninterrupted improvement resulting in a condition that the patient considered practically a normal one. The apparently favorable action of the atoxyl treatment; the fact that with a whole vertebra entirely destroyed, and without the slightest artificial support, the patient suffered no inconveniences whatever from this pseudoarthrosis, while at no time were there paralytic symptoms of any sort.

118. **Climatic Treatment of Tuberculosis.**—Hinsdale is firm in the belief that for the majority of incipient cases, when the patient can well afford it, life in a selected locality in the west offers the best prospect of cure; but that for eastern patients a period of training in an eastern sanatorium is highly desirable—the first and most important stage in beginning any climatic treatment. He believes that dryness, sunshine and altitude are features of the best climate, but that they decidedly disagree with some patients when presented in extreme doses as in some of our southwestern resorts. Hinsdale agrees with others that given simple pulmonary tuberculosis (not far advanced), somewhat over 60 per cent. of such patients will do better and live longer in the West than they would in the East, supposing every other consideration to be equal; also that nearly 40 per cent. of the total will do better and live longer in the East than in the West, similar conditions prevailing in both places. Of course those comprising this latter 40 per cent. in the East may not do quite so well proportionately as those of the 60 per cent. in the West, but in the East they will be doing the best that they can, and a small majority of the 40 per cent. can be cured under eastern conditions that would probably fail utterly in the West. In other words, conditions other than money, nostalgia, etc., should enter into the question of cases of tuberculosis being treated and remaining West or East. Doubtless every patient who is able to afford it easily should try the West; the first and essential part of the western trial being a period of regulated régime in the East.

119. **Common Colds.**—This is a statistical paper. Honeij details the results of an investigation of the prevalence of common colds and the economic loss due to them, together with a study of the various types of colds, sources of infection, the vocations most affected and other facts of more or less interest and importance.

8 Evidence of Recent Severe Illness Afforded by the Nails. N. Flower and Sir S. Wilks.

2. **Heart Failure.**—The point is emphasized by Mackenzie that an individual affected by a heart lesion which diminishes

his working force must live within the limits of his powers. This can only be done by the period of rest being sufficient to restore the exhaustion of the work force. In this way alone will heart failure be avoided, and a reasonable prospect of longevity be attained. Treatment need not be given in the presence of any abnormal conditions unless there is distinct evidence of heart exhaustion. Where there is such evidence, then the treatment, in the first place, must consider the possibility of diminishing the amount of daily effort. From the point of view that heart failure arises because the period of work is so great that the period of rest cannot restore a sufficient amount of work force, the essential principle of treatment becomes self-evident—namely, rest. The success of the treatment depends entirely on the amount of rest the heart has procured. Mackenzie thinks it probable that drugs which have such a potent and beneficial effect on the heart as those of the digitalis group owe their good effects mainly to the amount of rest procured by the slowing of the heart's rate. At all events, in the researches Mackenzie has been carrying on for some years, the patients who have obtained the greatest benefit from digitalis were those in whom the heart's rate was decreased by the digitalis. He has repeatedly seen relapse of patients coincide with an increase in the pulse-rate when the digitalis was diminished or left off.

The vast majority of patients in whom digitalis acts with such marvelous effect in slowing the rate and improving the condition are those affected by auricular fibrillation. Hearts with the normal rhythm are seldom so sensitive to digitalis, and in them there is not the same tendency to slowing of the rate. Mackenzie says that it is a matter of every-day experience to find individuals with a murmur or an irregularity, who for years have been subjected to treatment and made to visit health resorts, for a condition which neither indicates heart failure in the present nor its likelihood in the future. The fact that heart failure did not arise has probably been attributed to the precautionary measures. From this comes the belief in the efficacy of many of the drugs and methods in use to-day. When many of the vaunted remedies are carefully investigated, their uselessness becomes evident. There are many conditions in which rest alone fails to benefit the heart, as when the heart is invaded by a toxin, or rendered irritable from some lesion in the organ itself, or when the ventricle in heart-block contracts so seldom as to endanger life. For these and many other conditions, we are absolutely without any means of meeting the impending and actual danger, and yet we are kept in ignorance of this fact because writers pour forth a stream of remedies for any and every kind of heart trouble. Were we more alive to our own limitations, we should be more industrious in the search for real and valuable remedies.

3. **Chronic Colitis.**—Appendicostomy is favored by Power in these cases of ulcerative colitis. The products of the ulceration are very abundant, and their absorption is one of the most serious dangers of the disease. It is important, therefore, to cleanse the bowel and to keep it free from putrefying products. Drainage through the appendix enables this to be done in the most satisfactory manner. The operation of appendicostomy is not so serious as that required for removal of the appendix during the quiet stage. It is very effective, and the fistula can afterward be closed without trouble; indeed, in some cases the difficulty is to prevent spontaneous closure. On the other hand, Power emphasizes that it must be clearly understood that appendicostomy will not cure ulcerative colitis, and the friends of the patient should have this clearly explained to them at the time of the operation, or they will be disappointed. The object of the operation is to keep the bowel clean and to prevent the absorption of toxic products. The ulcerative process continues until the patient becomes immune either by a natural process or by artificial means. Appendicostomy, therefore, prolongs the life of the patient, and thus gives him a better opportunity to be cured.

In the cases which have come under Power's observation (ten) the first effect of appendicostomy has been a material improvement in the condition of the patient, even in the most advanced cases. The temperature falls, the appetite returns and may remain good permanently. The improvement in the general condition, however, is not maintained in its full extent, and a relapse occurs after a week or two. These relapses are a cause of great anxiety, but, so far as he has seen them, they have only been temporary, and the net result of the operation has been a slow but interrupted progress to recovery after months of illness. Power has tried many different drugs as local applications in these difficult cases of ulcerative colitis. Phenol in all its forms, however disguised, has caused carboluria so often that he has ceased to use it. Bismuth salicylate, perchlorid of mercury, biniodid of mercury and boric acid caused irritation in the earlier stages and were discontinued. Bismuth carbonate (15 grains to 1 pint) and potassium permanganate (1 in 30,000) were some of the drugs which proved most useful and were soothing. In the later stages of the disease irrigation with perchlorid of mercury (1 in 20,000), zinc sulphate (4 drams to 3 pints) and silver nitrate in the strength of 5 to 10 grains to the pint of sterilized water gave the best results when they were used alternately. Ionized irrigations were employed on several occasions, but he could not satisfy himself that there were any marked improvements.

4. **Vaccines in Acute Mastitis.**—Benian cites a considerable number of cases of acute mastitis and chronic suppurating sinuses of the breast in which the vaccine treatment was eminently successful.

5. **Erythema Nodosum Following Measles.**—In 9 out of 300 cases of measles erythema nodosum developed. In most of the cases about ten to fourteen days had elapsed since the first onset of measles before the erythema nodosum made its appearance. In half the cases the first symptom was pain in the joints, followed by the erythema in about twenty-four hours. There was no history of rheumatism or contact with rheumatic fever in any of the cases, and no rheumatic or cardiac lesions were found in any of the patients. The question of sore throat before or at the time of the measles rash was carefully gone into by Joynt, but it was present in one case only. So far as he knows no other case of erythema nodosum has occurred in the sphere from which these cases have been collected. Seven of the cases occurred among the poorer class attending the hospital, and two were private patients in fairly good circumstances.

6. **Surgical Treatment of Pulmonary Cavities.**—Harris reports another case (his second) in which opening a pulmonary cavity and treating it surgically seemed indicated. He regards the procedure as being useful and fairly safe in non-tuberculous cases in which the cavities are but few in number. The result was all that could be desired. This case presented one or two special points of interest. Thus there were no adhesions found strong enough to prevent the lung from retracting from the wound. Neither was there anything to guide the palpating finger to the dilated bronchus. Again, the movements of respiration, so much exaggerated anteriorly as compared to the movements of the ribs posteriorly, repeatedly pulled out the tube from the bronchiectasis, for although the latter was carefully mapped out prior to operating, as soon as air entered the pleura the bronchiectasis was drawn upward and toward the mediastinum. The operation was therefore divided into three stages. When efficient drainage of the bronchiectasis was established, the temperature fell to normal, and remained so with cessation of all sweatings. Lastly, the collapsed lung and injured pleural cavity were subjected to Roentgen rays for twenty minutes on four occasions.

9. Also published in the *British Medical Journal*, April 15, 1911.

10. Also published in the *Journal of Obstetrics and Gynecology of the British Empire*, February, 1911.

11. **Skeleton Changes in Acromegaly.**—After having examined a considerable number of skulls, Keith concludes that the changes in acromegaly are of the nature of true growth, and are apparently due to the circulation through the body of a substance formed in the pituitary. This substance seems only to sensitize the tissues, the actual cause of their growth being mechanical stimuli arising from muscular action and mechanical movement. The growth changes seen in the acromegalic are of the same nature as those which occur normally in anthropoids and in the Neanderthal race, and both are probably due to a condition of hyperpituitarism.

12. **A House Epidemic of Typhoid.**—A house epidemic consisting of seven cases of typhoid is reported by Wilson and Sinton. The first patient was the mother who had eaten cockles a fortnight before her illness and who became a bacillus-carrier. The infecting bacillus was at first immotile when grown on agar, and was somewhat inagglutinable. The mother gave birth to a healthy full-term child, and her milk was very rich in agglutinins.

14. **Prolapsus Uteri: Ventrofixation.**—As experience has tended to prove that permanent reliance cannot be placed on any method of suturing the fundus, O'Connor adopted the following procedure with, so far, most promising results. The abdomen having been opened by a low central incision, the uterus is drawn forward with the left hand, and a small transverse cut is made at the site of the reflection of the peritoneum on the anterior surface of the uterus (exactly similar to the preliminary peritoneal incision in hysterectomy). With the handle of a knife or with the right index finger, the peritoneum with the bladder is pushed downward and forward, until a space of about an inch square is left on the anterior surface of the cervix. The peritoneum on each side of the exposed area is seized with pressure forceps, and is retracted out of the way, while he passes three strong catgut sutures, about one-third of an inch apart, through the denuded surface of the cervix, deep enough to get a firm grip of the cervical muscular coat. The needles having been removed, he draws the ends out, respectively, on each side through the recti muscles, by the aid of Childe's ligature forceps. Thus the peritoneum is excluded, and the exposed cervical connective tissue is brought into direct apposition with the recti. Before tying these three fixation sutures, O'Connor always closes the peritoneal layer of the parietal wound by a continuous catgut suture, the first few loops of which he passes also through the uterine peritoneum just above the denuded area, in order that no raw surface may be left for the omentum or the intestine to adhere to. The three cervix-recti sutures are next tied, and the muscles are approximated through the remainder of the incision by another catgut suture, the rectus sheath is similarly closed, and the skin is united by a subcuticular silk thread.

20 Mixed Morbid Conditions in the Chest. J. W. Carr.
21 Acute Bronchial Affections in Young Children. T. D. Lester.

17. **Dyspnea in Nephritis and Diabetes.**—Urgent dyspnea, Tirard says, is always of grave import in nephritis and diabetes. In nephritis, when dyspnea is found, one must determine the cause, and to which of these categories of dyspnea the case belongs. It is essential for the purpose of treatment. The treatment should be hot-air baths and purgatives. Diaphoretics may do good in one group, and in another group it may be necessary to withdraw the fluid from the legs, the abdomen and the chest. In yet another group of cases, success may be obtained by stimulants and by expectorants. In diabetes, when dyspnea develops, one must examine the chest very closely for evidence of tuberculosis or other pulmonary trouble, and must also examine the urine closely for evidence of acetone or diacetic acid, remembering that this may be present even when, or particularly when, the sugar has shown signs of diminishing. *When the sugar diminishes and dyspnea is worse, it is almost always certain* that acetone or oxybutyric acid or diacetic acid will be present. Another practical conclusion is that when this symptom of air-hunger develops in patients who are not known to be diabetic, or who are known not to be diabetic, or when *there is marked apathy or drowsiness in patients who are being* fed by the rectum, it is advisable to examine for acetone and diacetic acid, and when these substances are present, whether one is dealing with diabetics or non-diabetics, it is always a safe rule to give alkalies and carbohydrates.

19. ***Acute Suffocative Catarrh of Pneumococcal Origin.***—West regards the association of bronchitis with pneumonia as being always serious, but the gravity depends on the relation between them. Pneumonia occurring in the course of an ordinary bronchitis is an awkward complication, but not necessarily fatal. If, however, the signs of bronchitis develop in the course of a pneumonia, the result is almost invariably fatal. The meaning of the bronchitis in the two cases is different. In the first it is merely an association of two independent diseases. In the second the bronchitis is a sign of pulmonary failure, the result of the strain thrown on the lungs by the pneumonia; the lungs having done all they could to cope with the pneumonia, but failed, the signs of the failure being those of bronchitis. *This is sometimes called secondary congestion of the lung.* But the congestion of the lung may be primary. It may be coincident with the onset of pneumonia, and produce very grave symptoms. It may even be associated with hemoptysis, which is sometimes considerable. Yet as the consolidation develops in some part of the lungs, the primary general congestion may subside and the physical signs gradually limit themselves to those of ordinary consolidation. This may be compared to the widespread initial swelling which occurs in the subcutaneous tissue precedent to the development of a boil, and which rapidly disappears as soon as the infection localizes itself. If, when the pneumonia localizes itself, this general congestion still continues, it constitutes a very grave complication. This general congestion, bronchial as well as pulmonary, may also exist independently of any, or of anything but slight, consolidation. It is then a condition of the greatest gravity.

28 *A Case of Anomalous Cutaneous Eruption. W. K. Wills.
29 Paratyphoid Fever. G. Peacocke.
30 Fractures of the Patella and Their Surgical Treatment. C. B. Lockwood.

22. **Rheumatic Manifestations in Childhood.**—In Moon's opinion, there is one thing more important than all else in the treatment of rheumatism, and that is rest. Thus the rheumatic nervous children should have their school hours reduced, and in particular should not be allowed to work in the evening; in addition, an hour's enforced rest in the middle of the day is often advisable in such cases. But it is above all in the cardiac manifestations that rest is of such sovereign importance; a couple of months or more in bed is none too much when a cardiac lesion has been detected, and when the child first gets up, great caution must be exercised for some months longer. In the present state of knowledge this is far the most important thing to be done in order to save the heart from an entire breakdown of compensation. It is important that these children be warmly clad, but there is no reason why they should not eat the same food as ordinary healthy children. Care should be taken that they are not overworked at school or over-fatigued by too much exercise; any indication of this, such as headache, restlessness at night or general nervousness should be promptly treated by stopping school work, resting at home for two or three weeks, and, perhaps, it may be well to give small doses of arsenic and iron or cod-liver oil and iron, always bearing in mind the insidious attack which rheumatism so often makes on a vital organ.

28. **An Anomalous Cutaneous Eruption.**—The patient whose case is reported by Wills was a boy, 6 years old, who had had tonsillitis, cervical adenitis and sore throat. The skin eruption followed. The skin over the shoulders became scaly, and this condition spread in a couple of weeks to the whole trunk, and to a lesser extent to the thighs, arms, neck and face, but did not involve the hands, feet or scalp. By the end of the month, while the scaly condition was extending, the parts first involved were showing more inflammatory changes, and a small amount of serous discharge appeared, and the scales were shed, leaving a raw surface. At the end of three weeks, the whole of the trunk had become "raw," the conjunctiva had become involved, the gums and lips were also ulcerated, and the condition of the child most pitiable. The discharge had soon become purulent and offensive, but no local treatment seemed in any way to allay the symptoms. The temperature was of a septic type, but did not run very high. He presented the appearance of a profound toxemia. Cultures were made from the throat lesions, from the nose, eye and the skin lesions, and all were returned "positive Klebs-Loeffler." Almost immediately after injecting diphtheria antitoxin improvement began to set in. The local treatment had comprised boric ointment and zinc and mercury applied on lint.

34 Transient Retention of Nitrogen During Protracted Delivery. A. Couvelaire.

31. **Polyneuritis During Pregnancy.**—Job has compiled sixteen cases of myelitis or polyneuritis occurring in the course of toxic vomiting in pregnant women. In each case in which the pulse is recorded the rate had been over 100 before the signs of paralysis developed, confirming the necessity for active measures whenever the pulse runs over 100 in the vomiting of pregnancy. Five of the women died; six were delivered at term but most were left with severe functional disturbances. In five cases the gravity of the symptoms led to early interruption of the pregnancy and the outcome was by far the most favorable in this group. In a case reported in detail, abortion was not induced until nearly two months after the first symptoms and the patient did not long survive. The auto-intoxication seemed to follow a regular course in the entire sixteen cases, affecting first the vomiting center, then the cardiac center and, finally, the peripheral nerves. The nervous symptoms may continue to develop after all the gastric symptoms have subsided and, once installed, they show scarcely any tendency to subside so long as the pregnancy persists. The prognosis is better with abortion or premature delivery induced in time.

Annales des Maladies des Org. Génito-urinaires, Paris

March 15, XXIX, No. 6, pp. 481-576

35 *Calculus in Kidney or Ureter in Children. (De la lithiase rénale et urétérale chez l'enfant.) M. Rafin.
36 Action of Colon Bacillus on the Kidney. (Action du "Bacterium coli" sur le rein.) F. Cuturi.
37 *Technic for High Incision of the Bladder. (Taille hypogastrique.) O. Pasteau.

35. **Calculus in Kidney or Ureter in Children.**—Rafin has been able to collect thirty-nine cases of this kind in children in which the stones were found in the kidney or ureter at an operation or necropsy. He has also operated in two cases. The symptomatology seems to be the same for children as for adults, but radioscopy is even more instructive with children. The knowledge that there are stones located at different points through the urinary apparatus is important, as the gravity of the condition is enhanced by the multiplicity of the localizations. Nephrotomy seems to be even less injurious in children than in adults. The immediate results were good in all the cases after the operation; the four fatalities were all in cases with severe infection and multiple concrements. The end-results are known in only very few of the children. It is more than probable, he thinks, that in many cases of urinary calculi in adults, the concrements had commenced to form in childhood, as in a case cited in which a stone, weighing 25 gm., was removed from the ureter of a girl of 16, who for ten years had had occasional kidney colics and hematuria. Five of the thirty-nine children were under 5, eighteen between 5 and 10, and twelve between 10 and 15. The lithiasis was exclusively on the right side in twenty-one cases and bilateral in six of the thirty-five in which the localization is mentioned; the concrements were in the right kidney alone in seven, right ureter alone in eleven, both kidney and ureter in two, while both were involved on both sides in three cases and in another bilateral case the bladder was also involved, as also in another case exclusively on the right side. In one of Nicolich's cases, radioscopy showed a stone in the right kidney, three in the left, and five in the left ureter. The latter were spontaneously expelled and the kidney stones removed by operation, after which radioscopy showed the entire urinary apparatus clear of concretions. In conclusion Rafin reiterates the comparative harmlessness of operations on the urinary apparatus in children and the necessity for keeping watch over the little patients so as to institute medical measures to ensure a permanent cure of the infectious process; it is liable to persist in a latent form unless diligently sought and eradicated.

37. **Technic for Suprapubic Incision.**—Pasteau stands on the left side of the patient and raises the pelvis before opening up the prevesical space. Then, when ready to incise the bladder, he has the pelvis raised still higher, as much as 35 or 40 degrees, not lowering it until the bladder has been sutured again. He distends the bladder with air and makes the incision in a part of the wall lifted up by two catgut threads run into the wall on each side of the median line, these threads aiding later in the suture.

40 *Syphilitic Jaundice. (Ictère syphilitique—Ictère hémolytique ou sanguin.) E. Gaucher and Giroux.

40. **Syphilitic Jaundice.**—Gaucher and Giroux report two additional cases of syphilitic jaundice accompanying the secondary manifestations and developing with the clinical and blood findings of acquired hemolytic icterus. There was no general reaction nor signs of biliary intoxication, pruritus or bradycardia. The destruction of the red corpuscles was due to their abnormal fragility in one case and in the other to the presence of hemolysins in the circulating blood. Both types differ entirely from catarrhal jaundice which is an ordinary icterus with no syphilitic features.

41 *Treatment of Extensive Phlegmon of the Synovial Sheaths in the Hand. (Remarques sur le traitement des phlegmons graves des gaines synoviales de la main.) P. Lecène.

41. **Extensive Phlegmon of the Synovial Sheaths in the Hand.**—Lecène has never obtained any benefit from Bier's method of inducing hyperemia in these serious cases, and quotes Forsell's actually disastrous experience with it. He adds that even in Germany this method is comparatively little used now in this class of cases. The best results are obtained, he asserts, by a long incision following the tendon sheath and extending the whole length of the infected segment. According to its location, the incision starting above the wrist was carried to the tip of the thumb, of the little finger or the second finger in the four cases reported. The grave lesion healed without impairment of the functioning of the wrist in each case, and the fingers regained normal functioning in all except two of his patients, in whom the little finger was left stiff, the tendon in this finger having been totally destroyed by the suppurative process. His patients were two men and two women, all in the forties.

45 *Rupture and Perforation of Pyosalpinx. F. Lejars.

45. **Rupture and Perforation of Pyosalpinx.**—Lejars reports another case of this kind to supplement five others he has previously reported. He also reviews what Bonney *and others* have published on the subject, emphasizing the necessity for bearing in mind the possibility of rupture of a pyosalpinx when confronted with menacing peritonitis of unknown origin. The history of the case generally shows some acute flare-up of an infectious process just before and a slight contusion afterward inducing the rupture or perforation. The pyosalpinx may also rupture during delivery or measures to induce abortion. Chevassu recently reported a case of this kind; a woman introduced a long bone cannula supposedly into the uterus and during the night abdominal symptoms developed with fever; *pulse was weak and* 130, and the abdomen was found flooded with pus traced to one tube containing several small interstitial abscesses. The tube was removed, as the condition of the patient did not permit hysterectomy. She died in less than five days. Mary has encountered *three similar* cases in lying-in women. All succumbed and one tube was found perforated. Puerperal infection was the presumptive *diagnosis and* the flaring up of a puerperal process may lead to rupture of a hitherto latent pus tube. Galliard has reported a case in which a woman convalescing from typhoid suddenly developed severe colic, vomiting and tympanites, high fever and pulse of 160. When the abdomen was opened no perforation could be found in the intestines but the right tube was swollen and perforated and it was excised; the patient rapidly recovered. Typhoid bacilli were cultivated from the pus in the excised tube. Lejars found streptococci exclusively in the pus in one case of diffuse peritonitis from rupture of a left pyosalpinx, and death speedily followed. Latzko and Cotte have each reported a case of ruptured abscess in an ovary. Lejars has also encountered two cases in which the tube had perforated and had become gangrenous, the conditions resembling exactly *those in a gangrenous appendix.* The *peritonitis following* perforation of a pus tube is, as a rule, unusually grave and rapidly progressive; the pains are localized in the pelvis, and are severe from the first; the findings with vaginal palpation may give the clue to the suppurating focus in the uterine adnexa. The condition is frequently mistaken for appendicitis *or a ruptured tubal pregnancy. Differentiation* is important on account of the necessity for prompt operation without temporizing; removal of the diseased tube and possibly the uterus with the adnexa is the safest course.

54 Anaphylaxis of Pregnancy. (Die Ueberempfindlichkeitserscheinungen in der Schwangerschaft.) A. Hirschberg.

50. **Diagnostic Importance of Paralysis of the Larynx.**—Grabower insists that examination of the larynx is as important as that of the fundus of the eye in all nervous affections, and should be a routine procedure. Paralytic conditions in the larynx may exist without causing appreciable symptoms; they may even be the earliest sign of tabes dorsalis and possibly permit effectual treatment before irreparable lesions are installed. The *laryngeal disturbance* with multiple sclerosis may be merely a tremor of the vocal cords or a twitching movement, but laryngeal symptoms deserve to rank as a diagnostic measure with nystagmus and temporary blanching of the papilla. *Paralysis in the* larynx is, further, characteristic of syringomyelia, especially unilateral recurrent paralysis. Grabower's research has shown that the posterior crico-arytenoid muscle has only 230 nerve fibers in comparison with the 680 fibers of the inner portion of the thyro-arytenoid muscle; it is thus less resistant and becomes paralyzed more readily. As tuberculosis frequently begins in the bronchial glands and these compress the recurrent laryngeal nerve, paralysis of the posterior crico-arytenoid muscle controlling the vocal cords may be observed in the very earliest stages of incipient tuberculosis. The right recurrent nerve is more liable to be compressed in this case than the left, as the *right bronchus is* higher than the left and thus closer to the right inferior laryngeal nerve. The left is more liable to suffer from compression by aortic aneurysm as the left nerve encircles the arch of the aorta and is thus liable to be compressed quite extensively. The right inferior laryngeal nerve may be compressed with an aneurysm in the subclavian artery. Enlargement of the thyroid *may* also compress this nerve, and signs of paralysis in the larynx indicate extension of the goiter into the depths. *The same is true of tumors in the esophagus,* the posterior crico-arytenoid muscle feeling the effects first but the rapid growth of *the carcinoma soon involving* the recurrent laryngeal nerve. Another cause of peripheral paralysis of the recurrent nerve is a healed inflammatory process in the right apex of the lungs. Nerve substance may be found embedded in the cicatrix at necropsy; there probably had been recurrent paralysis during life causing moderate hoarseness for which no cause could be discovered. The hoarseness may have subsided and yet the unilateral recurrent paralysis must have persisted throughout life, the sound *vocal cord vicariously acting* for the paralyzed one. The right inferior laryngeal or recurrent nerve passes close to the right apex of the pleura, and is thus naturally drawn *into the retracting cicatricial tissue* as the inflammatory process in this region heals. Mitral stenosis is sometimes accompanied by paralysis of the left recurrent nerve. In regard to laryngeal paralysis with brain tumor, he says that unless the medulla oblongata is investigated, the examination cannot be regarded as complete. Among other symptoms in the larynx mentioned is the twitching of the vocal cords liable to be noticed with a *tumor in the frontal* lobe. Twitching of the vocal cords, Grabower states, is presumptive evidence that the tumor is in the base of the frontal lobe and that it is actively growing.

51. Summarized in THE JOURNAL April 22, 1911, p. 1224.

52. **Improved Method for Artificial Respiration.**—Meyer has modified the Silvester method, drawing the arms upward but pressing them down toward the floor, the body thus assuming the opisthotonous attitude, the head and heels bent backward, the body bowed forward, over the cushion under the shoulders. *Another point is that* the arms are held with the four fingers above the elbow, on the inside, the thumbs on the outside of the arms. This permits a stronger control of the arms in pushing them toward the floor. This modified technic floods the lungs much more profusely with air.

53. ***Flat-Foot and Arthritis.***—Ewald presents evidence to show that the changes of flat-foot leave disturbances such as in all other joints are known as deforming arthritis.

57. Phlegmon in Stomach Wall.—Koenig's patient was a woman of 28 whose illness had commenced with high fever, headache and vomiting; typhoid had been assumed at first. After subsidence of the acute symptoms pains in the stomach, independent of intake of food, persisted, with oppression and vomiting at times of brownish yellow masses but there was no blood in the stool and no diarrhea and the gastric chemistry was approximately normal. The appetite remained good but the woman grew constantly thinner, losing over 50 pounds in weight; palpation revealed a soft, transverse, long tumor which slid about under the fingers. The trouble proved to be a suppurative inflammation of the stomach wall, a purulent gastritis, which had passed into a subacute stage. The mucosa was perforated in various places, almost like a sieve, while the serosa showed signs of peritonitis and adhesions were forming. It is the first case on record in which the process was inspected at such an early stage and excision of the lesion restored the patient at once to health. The case shows that even after the phlegmon has emptied itself and the pus has been vomited up, yet the lesion does not necessarily heal but may persist in a subacute form, and progressively debilitate the patient. A gastro-enterostomy would not have mended matters, while resection without preliminary opening up of the stomach proved a complete success, the soft tumor-like mass into which the phlegmonous part had been transformed being readily excised.

58. Myelitis with Recurring Endocarditis.—Lewy's patient was a woman of 37 with chronically recurring endocarditis and an inflammatory affection of the spinal cord and meninges located at three different points. The affection ran a separate course at each of these points, each being preceded by a recurrence of the endocarditis. During the year and a quarter before the final fatal termination the symptoms had suggested the most various and erroneous diagnoses until microscopic examination cleared up the mystery except in regard to the puzzling behavior of the reflexes. Lewy has not been able to find any similar case on record. The foci in the spinal cord were of a chronic degenerative character in the anterior horns of the sacral segment of the cord, while the process in the upper dorsal segment was a circumscribed meningitis, and the final trouble was an acute disseminated encephalomeningitis.

60. Kala-Azar in Greece.—Christomanos recently found the Leishman-Donovan bodies in two hospital patients at Athens, and he thinks that kala-azar is probably prevalent in Greece although it has hitherto been diagnosed as a form of malaria, rebellious to quinin. A certain disease described by Hippocrates as endemic in Greece seems to have been kala-azar, which thus is shown to be not a new importation. No benefit was derived in Christomanos' cases from either atoxyl, arsacetin or salvarsan. Forty-eight hours after an intravenous injection of 0.35 gm. salvarsan the parasites were found still numerous and unmodified in the blood taken from the spleen. Quinin and change of climate gave no relief. The first patient, a girl of 18, has had fever constantly twice a day for nine months; the reactions for syphilis, Malta fever and tuberculosis are negative. The blood shows 1,700,000 reds, hemoglobin 30 per cent. The other patient is a man of 30 and he has had a chill and fever every evening for thirteen months. The spleen is enormously enlarged in both patients and the parasites can be readily detected in blood obtained by puncture of the spleen.

71 Etiology of Trachoma. C. H. Sattler.

63. Uterine Myoma.—Peham dreads the general anesthesia for a debilitated patient with myoma more than an operation. He comments on the bread-like consistency of myomas and the symptoms liable from pressure and traction on the uterus and on the adjacent organs. There may be no pains but when they exist they may be intensified during menstruation, the hyperemia of the myoma itself adding to the disturbances. Ascites is not unusual as a complication and thrombosis is favored by the pressure. In respect to palliative treatment, he remarks that the cures that have been reported after a course of baths must have been due to an erroneous diagnosis or to the approaching menopause in which the myoma retrogressed. Iodin and its salts promote absorption of inflammatory products and stimulate the circulation so that the general health is favorably influenced. The history of operative treatment of uterine myoma, he says, is one of the most brilliant chapters in gynecology, the mortality having dropped from 36.2 per cent. in 1878 (Gusserow), and 23.1 per cent. in 1891 to 3.8 per cent. in Döderlein's 388 cases of the last six years. Peham's mortality has been 5.4 per cent. in 164 laparotomies and 0.5 per cent. in 180 vaginal hysterectomies for myoma.

64. Chemical Processes in Urinary Lithiasis.—Schade's announcements in regard to the share of the colloids, especially fibrin, in the production of concrements in the body are reviewed below in abstract 75. He comments here on the new horizons opened for therapeutics and prophylaxis by means to prevent precipitation of colloids or to dissolve their precipitates when already formed. It is easy to do this *in vitro* and the task now is to discover some substance which will do this harmlessly in the body. He calls the attention of physicians at watering places, in particular, to this task as many of the problems involved can, perhaps, best be studied with mineral waters.

65. Nervous Disturbances during Salvarsan Treatment of Syphilis.—Heuser reports a case of papulous iritis a few days after intramuscular injection of 0.2 gm. salvarsan, followed by an intravenous injection of 0.4 gm. salvarsan. Then epileptiform seizures developed. The patient was a painter but there were no signs of lead poisoning; it is possible, however, that the lead might have created a predisposition. In a second case a young workman had paralysis of the vocal cords and soft palate three days after an intravenous injection of 0.5 gm. of salvarsan. No paralysis of this kind had ever before been observed at the clinic in the early stages of syphilis. No improvement was observed under calomel for several weeks but recently slight improvement has become manifest. This patient also presented occasional outbreaks of profuse perspiration during the two months he was in the hospital, suggesting a possible general injury of the nervous system. In a third case, ten weeks after a subcutaneous injection of salvarsan, severe symptoms on the part of the brain developed including choked disc, intense headache and facial paralysis with epileptiform seizures. Heuser is convinced that the cases of cerebral syphilis with these peculiar tonic-clonic spasms are encountered more frequently under salvarsan treatment than corresponds to our previous experience. He tabulates further the findings in regard to the presence of arsenic in the urine after salvarsan treatment; they show that from six to nine months after intramuscular injection arsenic can be detected in the urine (twenty-three cases) and three months after intravenous injection. In one case the arsenic was refound in the blood, also, two months after the intravenous injection. The experiences related apparently confirm, he thinks, Buschke's view in regard to the special affinity of salvarsan for nervous tissue. This neurotropic action of salvarsan is confirmed further, he adds, by Walterhöfer's case of peroneus paralysis, the cases of epileptiform seizures reported by Spiethoff, Gilbert and others, Jorgensen's fatality, and the disturbances in the auditory and optic nerves reported by Stern, Rissom and Bettmann.

68. Saline Infusion in Emergencies.—To save time, Hellendall carries in his obstetric bag a concentrated solution of chemically pure salt (8 to 30), so that all that is necessary is to dilute it with boiling water and cool to the desired temperature by standing in a jar of running water.

75. **Formation of Calculi.**—Schade has continued his research on this subject and states that colloids are involved in the production of stones in the body to a far greater extent than has hitherto been realized. The colloids throw down precipitates which assume the form of strata. Fibrin, for instance, has this power of stratification-precipitation to a marked degree. If it is deposited on an unattached particle, the stratification occurs concentrically. Crystalline substances deposited with it unite to form the concrement; this applies to all calculi formed in the urinary and salivary passages, in the pancreas or in the intestines, prostate or joints and also to the bilirubin-lime stones, but cholesterin stones are formed by the confluence of droplets. The problem of stone formation is brought nearer solution by the discovery of the participation of the colloids, he declares, and the outlook for therapeutics is broadened. It may be possible to alter the medium in such a way that the colloids, especially fibrin, may be prevented from precipitating; if the medium is rendered more alkaline, the colloid remains dissolved and no precipitation occurs. Changes in the electrolytic property may also check the tendency to precipitation of colloids. The benefit from mineral waters in some cases may be explained by their influence on the precipitation of colloids. In his experiments he found that antiformin would dissolve out the colloids, leaving the crystalline elements practically unaffected; the latter dropped to the bottom of the dish as the colloid framework was dissolved by the antiformin, confirming the large share of the colloids in the stone formation. In conclusion he calls attention to the efforts of Nature in this line; in the fresh-water crab (*Astacus fluviatilis*) typical stratification stones form in accessory cavities of the stomach by glandular secretions, the stones being formed of calcium carbonate and phosphate, with organic colloids, the so-called crabstones. They serve a physiologic purpose as a deposit to be drawn on when the crab casts its shell and a new one forms. The stones then drop out into the lumen of the stomach and are rapidly dissolved by the gastric juice and ferments and are absorbed in the intestine. Nature teaches us in this example that it may be possible to influence the pathologic concrements in man in a similar way when the conditions determining the solution and precipitation of the colloid elements in the stones are better studied.

77. **Deviation of Complement with Cancer.**—Caan applied the Wassermann test in eighty-five cases of carcinoma with positive findings in 41 per cent. The reaction was positive in six out of seven cases of carcinoma of the lip, in 67 per cent. of fifteen chancroids and epitheliomas, while positive findings were obtained in only 9 per cent. of the cases of mammary cancer and in 17 per cent. of the thirty-one gastro-intestinal cancers. He applied the deviation of complement test in all its various modifications in each case, with parallel findings.

78. **Recurrence in Nervous System after Administration of Salvarsan in Syphilis.**—Benario sent out a question blank to a number of physicians to collect their experiences in this line. In 126 (147) of the 14,000 cases in which salvarsan has been applied a neuro-recurrence was observed, and he classifies these cases under various headings and compares the findings with the experiences of others with and without salvarsan treatment. The total material confirms, he says, Ehrlich's explanation of these disturbances as manifestations of the syphilis in nerves enclosed in narrow bony canals, not of a drug toxic nature but the work of the few spirochetes left after the destruction of the majority of the spirochetes by the treatment. The striking clinical symptoms are not due to the extent of the process, he says, but to the confined site. Study of the data collected shows that the early secondary stage is peculiarly predisposed to these neuro-recurrences, as also the cases in which the primary sore is extragenital. The malignant character of these extragenital primary lesions, especially those on the head, the *chancres céphaliques*, is well known; the latter being near the central nervous system are peculiarly liable to affect it. Pre-existing headache also should warn against the possibility of neuro-recurrences; there had been intense headache in thirty-six of the sixty cases mentioned in the question blanks in which the headache pointed unmistakably to the injury of the central nervous system by the spirochetes. The conclusion naturally follows that patients with these four predisposing factors should be excluded from salvarsan treatment or its dangers should be fully aired. The data presented further emphasize the advantages of treatment by an intravenous injection of salvarsan, this being followed by a vigorous course of mercury, and this in turn with another intravenous injection of salvarsan. Elderly patients and those debilitated from any cause should be excluded from salvarsan treatment. Benario adds that the attention now paid to manifestations of syphilis in the nervous system will certainly redound to the benefit of patients, as more vigorous treatment will be instituted and the syphilis will be eradicated, thus saving many who might otherwise be candidates for serious irreparable cerebrospinal disease later.

80. **Tourniquet Sign of Scarlet Fever.**—Bennecke confirms the reliability of this sign, described in THE JOURNAL, March 18, 1911, page 859. The absence of the sign seems to exclude scarlet fever, but positive findings are sometimes obtained in other diseases.

Therapeutische Monatshefte, Berlin

April, XXV, No. 4, pp. 209-268

84 *Treatment of Placenta Prævia. R. Birnbaum.
85 *Treatment of Congenital Torticollis. (Der angeborene Schiefhals.) P. Glaessner.
86 *Successful Decompressive Trephining. (Erfolgreiche Trepanationen ohne Befund.) M. Lewandowsky.

84. **Treatment of Placenta Prævia.**—Birnbaum describes the treatment he advocates for the general practitioner, emphasizing that treatment must be begun the moment the diagnosis is made. He insists on shaving the parts and on the use of ten or twenty moist cotton wads for tamponing the vagina, instead of gauze, although the latter is better for the uterus itself. His experience with the Momburg belt constriction has been unfavorable, as he had severe collapse in two cases, and one patient died; for this death he regards the constriction as responsible. Great caution is necessary in moving the woman on account of the danger of air embolism and thrombosis. Massage of the legs is necessary from the first day after delivery unless symptoms indicate that thrombosis is already installed.

85. **Congenital Torticollis.**—Glaessner severs the muscles subcutaneously in the very mild cases in young children but otherwise exposes the sternocleidomastoid muscle and resects the fibers for a stretch of 1 or 1.5 cm., afterward applying a plaster cast in over-correction.

86. **Successful Trephining without Findings.**—Lewandowsky reports two cases in which the patients were restored to health by decompressive trephining although nothing was found when the skull was opened to explain the symptoms that had been

observed. The first patient was a woman of 36 who developed intense headache and symptoms indicating disease of the left hemisphere after a slight trauma—striking the left side of her head against the edge of an open door. By the end of a month she had seizures suggesting epilepsy, with right paralysis, total aphasia and stupor. Conditions were found apparently normal on trephining but there must have been a high tension in the brain as there was prolapse of brain tissue, but the patient improved remarkably by the next day. She still has traces of paraphasia but otherwise has been well during the four years since. In the other case, intense headache and tenderness in the region of the temple persisted for six months after the young man had been kicked in the side of the head by a horse, after which he had been unconscious for four days. The trephining showed apparently normal conditions with no sign of abnormal pressure or inflammation, but the headache never returned after the operation and the patient has been in perfect health during a year since. The strict localization of the headache, its tenacity and the lack of neurasthenic or hysteric symptoms and the complete recovery after the operation suggest that the trouble must have been some traction on the dura from a possibly slight fracture of the skull.

Therapie der Gegenwart, Berlin

April, LII, No. 4, pp. 145-192

87 *Epidemic Poliomyelitis. (Akute epidemische Kinderlähmung.) P. Krause.
88 *Radiotherapy of Internal Disease. (Der gegenwärtige Stand und die nächsten Ziele der Röntgen-Therapie bei Erkrankungen innerer Organe.) H. E. Schmidt.

87. **Epidemic Poliomyelitis.**—Krause has compiled a number of tables showing the geographical and chronological prevalence of this disease. Other tables show the development of the disease by groups compiled from the replies to the question blanks he sent out to physicians in the German provinces along the Rhine. The transmission of the disease by healthy carriers is further demonstrated by the material tabulated. A grandmother in one instance carried the disease from one grandchild to another who lived at some distance. Another table shows the ages of the patients in his compiled material. The majority were 2 years old (165); 101 were 3 years old, ninety-seven between 4 and 7, thirty between 8 and 10, three between 20 and 30, and two between 30 and 40, with eleven less than a year old. In Germany the months of August, September and October contained nearly all the cases. The mortality in all the epidemics tabulated was the lowest (5 per cent.) in the New York epidemic; it was 16.7 per cent. in Sweden; 14.56 per cent. in Norway, and 22.3 in Austria. The article is to be continued.

88. **Radiotherapy of Internal Organs.**—Schmidt refers in particular to the treatment of deep cancer and states that better results may be anticipated when we learn how to sensitize the deep-lying tissues. This is accomplished for superficial tissues by means to stimulate the metabolism, for which active hyperemia is the most effectual known to date. If we can learn how to induce local hyperemia in the deep cancers, the Roentgen rays reaching them will have their action immeasurably enhanced. He thinks that it may be possible to discover some serum or drug, which, like tuberculin, will have an elective action on the tumor tissue inducing a local reaction and thus sensitizing it for the Roentgen rays. At present the only way that this can be accomplished is by thermopenetration, that is, applying the high-frequency current, which permits the tissues below to be raised to any desired temperature while sparing the skin. He reports the details of a case of epithelioma of the nose which subsided under radiotherapy after two years but returned four years later. The patient refused operation and the ulcerating epithelioma subsided anew under the Roentgen rays applied the day after the mercury-vapor lamp had been used to induce a local erythema. Only four applications of the mercury light plus Roentgen-ray exposures were required before the lesion had entirely healed over. There has been no sign of recurrence during the three months since. The mercury light was applied again a few times to enhance the resisting power of the cicatrix. The task now before Roentgenologists is to improve the technic for inducing hyperemia in the depths to enhance the sensitiveness to the Roentgen rays, as we know that expelling the blood from a superficial lesion reduces its sensitiveness to the rays.

91 *Psychic Etiology and Treatment of Arteriosclerosis. M. Herz.
92 *Paroxysmal Hemoglobinuria. A. Krokiewicz.
93 Oculomotor Paralysis in an Infant. A. Purtscher.

91. **Arteriosclerosis and the Strenuous Life.**—Herz regards the subject of arteriosclerosis as one of the most vital of all for the medical profession not only on account of their patients but because physicians, themselves, are particularly prone to acquire arteriosclerosis or at least to imagine that they are acquiring it. He says that fully 300 out of the 3,000 physicians in Vienna have consulted him on account of arteriosclerosis, and although the fears of many were groundless, yet an unusually large proportion actually show signs of arteriosclerosis. For this he is inclined to incriminate the peculiarly strenuous life of physicians, their cares and worries, the constant strain on their sympathies, the harassing feeling that perhaps if they had treated some patient along other lines he might have done better. Herz comments on the fact that life has become so much more strenuous during the last decades. All feel that they must work under high pressure and provide for the future instead of enjoying life as they go along and providing only for the immediate present. He says that life has become Americanized, and that arteriosclerosis is becoming more frequent in consequence although it is more of a chronic cardiac and cardiorenal type rather than the angina pectoris type of former decades. Treatment and prophylaxis should aim to banish worry and gloom and promote cheer. Instead of impressing on the young constantly their duties and responsibilities to others and the state, they should be taught that they have a duty to themselves, to seek cheer and joy to alternate with work. Physicians must train their patients to look on the bright side of things and stop worrying, for there is not the least doubt, he reiterates, that every persisting worry or carking care is distinctly dangerous for the heart and kidneys, and physicians must strive to cultivate cheeriness. Herz applies to the medical profession Goethe's remark in regard to German literary men, namely, that the members of the medical profession are like billiard balls; each is intent only on going its own way, and if two come into contact they bound apart and go their separate ways with even greater energy and haste.

92. **Paroxysmal Hemoglobinuria.**—Krokiewicz reports a case of this kind in a man of 48, previously healthy. The paroxysmal hemoglobinuria was first observed seven years ago and since then he has had the attacks whenever he has been much chilled; great fatigue and excitement do not bring on the attacks unless accompanied by chilling. Sometimes the hemoglobinuria occurs without other symptoms but generally there is a sense of exhaustion, pains in the muscles, restlessness and headache, then in twenty minutes a chill and fever and after half an hour the urine is as red as Burgundy wine; it clears up again in the course of from two to five hours. While under observation the hemoglobinuria could be brought on like a laboratory experiment by having the patient hold his feet in cold water for a little while. A tourniquet applied to the thighs never brought it on, and the attack could be arrested by applying heat (water bottles to the legs). The attacks could be brought on at intervals as brief as twenty-four hours. Hemolysins were found in the blood and their presence in the blood accumulating in the viscera in consequence of the exposure to cold, with the local accumulation there likewise of carbon dioxid in the blood, produce conditions similar to those of Hymans' test-tube experiments. Hemolysis follows and the hemoglobinuria results; the whole process can be broken up by putting an end to the action of cold by warming the legs. The Wassermann reaction was positive in this patient which possibly throws light on the unusual lack of resistance to carbon dioxid on the part of the red corpuscles.

97 Chemical Study of Infants' Urine. (Chemische Teilerscheinungen im Harne gesunder und kranker Säuglinge.) E. Mayerhofer.
98 *Summer Heat and Temperature of the Home in Relation to Infant Mortality. (Sommerhitze, Wohnungstemperatur und Säuglingssterblichkeit.) H. Rietschel.

95. **Diagnostic Importance of Tuberculides in Infants.**—Lateiner regards the papulous or papulo-squamous tuberculides of infants as of blood-borne origin, and of diagnostic importance even when the tuberculide appears isolated. The Hamburger type is smaller, more superficial and free from a tendency to ulceration. Acid-fast bacilli can be regularly discovered in the papulous form in the various stages of its development, and the bacilli are capable of inducing fatal typical tuberculosis in guinea-pigs. In the ten infants with these tuberculides whose histories are reported, the cutaneous tuberculin reaction was the only other sign of tuberculosis in three; in six there was miliary tuberculosis. These tuberculides are encountered only in infants with tuberculosis of internal organs, and as they are so small and cause no disturbances they are often overlooked. They vary from a pinhead to the size of a hemp seed; they project very little; there is no encircling zone of inflammatory redness and no infiltration around. They are light red at first, then a livid brown, with a scab in the center, and when this is scratched off a shallow depression is left which does not bleed or weep. Some of the tuberculides may be very flat, without a scab, merely a dimple in the center. Lateiner found also, occasionally, small circular, slightly depressed scars of a livid brown color. From one to four tubercle bacilli were found in each tuberculide, and guinea-pigs inoculated promptly developed typical tuberculosis. A single tuberculide of this kind on the upper arm was the only manifestation of the tuberculosis in one case. In another there was one on the dorsum of one foot and three on the sole of the other, with signs of tuberculous meningitis. Other infants had one on the knee and one on the foot; another, several on feet and fingers; one a pin-head tuberculide on the elbow; another, several on leg and forearm, and still larger numbers on some of the others. In one of the infants the first two nodules subsided and four others developed elsewhere.

98. **Summer Heat and Infant Mortality.**—Rietschel has been examining conditions in the homes of the poor in Dresden in regard to the actual temperature of the rooms during the summer. Maximal thermometers or thermographs were installed and the findings recorded in daily visits by his aids. The research was limited to the tenements or houses in which more than one infant had died in the last five years. The summer was an unusually cold one, but the thermometers registered for weeks at a time in the rooms where the infants lived over 25 C. (77 F.) and in some days up to 35 and 37 C. (95 and 98.6 F.) with an outdoor temperature of 23.5 and 21.3 C. (74.30 and 70.34 F.). The heat in the living room is thus shown to be intense in the homes of the poor and this keeps up for weeks and months and is, he is convinced, the direct decisive factor in infant mortality during the heated term.

100 *Cholangiocystostomy. J. E. Lohse.

100. **Cholangiocystostomy.**—Lohse commends the palliative operation he performed in a case of severe cholemia from cancer of the common bile duct. The patient was thus tided past the dangerous period of cholemia and survived in comfort for nearly three months afterward. A long forceps was passed into the gall-bladder and through it into the adherent liver until the tip could be felt through the convex margin of the liver. A thick drain was inserted into the passage thus formed and the wound sutured around it. Only a little bile escaped the first day but the amount increased to 200 c.c. by the third and by the end of two weeks the jaundice had disappeared.

102. **Tubal Sterilization.**—Labhardt describes a method of subserous resection of the tubes in common use at von Herff's maternity at Basel. Sterilization is regarded as a matter of course in cases of severe prolapse of the uterus in multiparæ over 40. He has applied the Asch method in thirty cases without a failure, but during the last two years he has avoided the disadvantages of this technic by drawing out the proximal tube for 2 cm. beyond its peritoneal mantle. The stump is then cut off and what is left withdraws into the depth of the empty mantle of the peritoneum which is then sutured and soon grows together, shutting off the stump of the tube entirely. This technic can be applied by the vaginal or abdominal route, and has several advantages, he declares, over other methods in vogue.

April 2, No. 14, pp. 421-452

109 Eosinophil Cells in Sputum in Asthma. M. Pennetta.

108. **Acute Infections of Unknown Origin.**—Baccelli refers in particular to what Leube calls cryptogenetic infections but which he designates as infections of latent origin. He claims that the conception of toxemia resulting from bacterial invasion originated in the Rome clinic before the discovery of the tubercle bacillus. The infectious germs may be classed, he says, as those inducing fever, those inducing inflammation, neurospastic conditions, neuroparalytic conditions and abnormal conditions in the blood, or combinations of these types. Differentiation of the cause of the infectious process is frequently impossible; sometimes it invades the blood first and the tissues later, sometimes the germs localize first in the tissues and pass later into the blood, possibly intermittently. The specific reaction can never be regarded as absolute, he continues; it is merely one important symptom to be estimated in connection with others. From these and other arguments cited he concludes that the aim should be to stimulate the production and the functioning of the phagocytes in all these infections of unknown origin at least; by this means the toxic substances in the blood are rapidly neutralized, and the supreme means to accomplish this is by intravenous injection of mercury bichlorid. His formula is 0.01 gm. mercury bichlorid, 0.075 gm. sodium chlorid and 10 gm. water. This injection can be repeated two or three times in twenty-four hours in the severest cases. Immediately after the injection the temperature drops, the synthetic reaction on the part of the organism to the infectious cause reduces the intensity of the infection, and he reports a number of instances to show the benefit that follows this measure. In one case of acute infectious disease, which no one was able to explain, a turn for the better followed the mercurial intravenous injection and the patient was soon restored to health. Baccelli has collected a number of similar testimonials to the life-saving efficacy of the measure and has accumulated an imposing array of testimony during the twenty years or more since he has been advocating this heroic intravenous medication.

110. **Echinococcus Disease of the Spleen.**—Biondi's patient was a country woman of 42, previously healthy. A tumor was noticed in the left hypochondrium after a childbirth, but no symptoms were felt for seven years, then high fever and intense pain in the epigastrium, radiating to the back and hypochondrium, developed, with obstinate constipation. The fever dropped by a crisis and the pain in the epigastrium subsided but that in the left hypochondrium persisted, and there was pronounced eosinophilia with slight albuminuria. The operation revealed non-suppurating, multilocular hydatid cysts in the spleen, which was adherent to the diaphragm, colon and to the wall of the vena cava, but the splenectomy was finally completed.

120 *Relief of Disturbances in Swallowing by Compression of the Ear Region. (En simpel Metode til Bekæmpelse af visse Former af Synkesmerter.) P. T. Hald.

118. **Outlook of the Medical Profession.**—Scheel discusses the prevailing tendencies in regard to medicine and the medical profession and the importance of organization, commenting on the remarkably small part taken in public affairs by physicians as a rule. This, he declares, is the more striking as logically medical men should be the leaders in the movements to improve the public welfare. He ascribes this to the fact that physicians by the nature of their work are inclined to be individualists, but he warns that this tendency should be combated.

120. **Relief of Disturbances in Swallowing by Compression of the Ear Region.**—Hald's experience has confirmed the assertions of Milligan and Horne in regard to the relief of pain in the throat by strong pressure applied to the tragus or mastoid process. In thirty-two cases he was able to relieve or banish completely the pains in swallowing with inflammatory affections in the tonsils or vicinity while in fourteen other cases no benefit was apparent. He uses for the compression a light adjustable frame with two pads to press on the tragus or mastoid process on each side. He explains the effect as due to the counter-irritation on the skin at a point where the sensory nerves are closely connected (centrally) with the sensory nerve supply of the tonsils.

122. **Salvarsan in Syphilis of the Nervous System.**—Marcus gives the details of a dozen cases out of a total of fifty cases of syphilis of the nervous system in which he administered salvarsan. Although the remedy is powerless against severe advanced paralysis or tabes dorsalis, yet the bladder and bowel disturbances and the pains were much ameliorated and improvement was apparent in other directions; in some patients the memory improved, others lost their apathy and difficulty in speaking. Five of the patients have died since the injection, one, eight days afterward from hemorrhage in the pons; one a month later from an accidental fall; one from recurring cerebral hemorrhage, and two from the progressive course of a glioma in the brain or of chronic pyelonephritis and cystitis with diarrhea. He states that there did not seem to be any connection between the medication and the death in any instance. But the severe diarrhea in the last mentioned case is not absolutely free from suspicion in this line, although he has never seen any mention in the literature of diarrhea following administration of salvarsan.

THE CAUSE OF INFLAMMATION OF CRANIAL NERVES AFTER THE USE OF SALVARSAN

A PLEA FOR THE INTRAVENOUS METHOD

JAY FRANK SCHAMBERG, M.D.
PHILADELPHIA

The new remedy, salvarsan, introduced by Ehrlich and Hata, has now been used in over 50,000 cases. It is conceded by all to be the most effective drug in syphilis known to medical science. Used properly in appropriate cases, it is as safe as most other potent remedial agents. Ehrlich regards salvarsan as less poisonous than mercury, if cases of heart disease and severe cases of paralysis are excluded.

The only disturbing results that have been reported after the use of salvarsan are occasional inflammation of cranial nerves, particularly of the optic and auditory nerves. Relative to the number of cases treated, the incidence of such complications has been very small, probably not one in a thousand.

It is probable, however, that some cases have occurred that have not been placed on record. Furthermore, the seriousness of such complications makes it imperative that their cause be thoroughly studied. Ehrlich has kept thoroughly in touch with these complications, and with all the evidence in his possession, he denies any etiologic relationship between the use of the drug and the development of the neuritis. He regards them all as cases of *neuro-recidiv*, i. e., fresh syphilitic neuritis.

There are a number of able clinicians abroad, however, who are not willing to exculpate the drug as a causative influence.

CASES OF OPTIC NEURITIS REPORTED

Professor Finger,[1] of Vienna, a noted syphilologist, has reported four cases (*the first four following*) of optic nerve disturbance:

Case 1.—Robust 19-year-old girl with initial lesion and beginning roseola. Infection eight weeks before. August 2, 1910, she received 0.45 gm. of salvarsan intragluteally. Prompt regression of lesions and negative Wassermann on September 20. October 5, she returned with headache, visual disturbance, vertigo, right-sided oculomotor paresis and beginning left optic neuritis. October 12, she was given 0.45 gm. salvarsan subcutaneously, in acid solution. October 28, mercury and iodids administered without result: neuritis of the right optic nerve set in.

Case 2.—Girl, 19 years old, with lues of two and one-half months' duration. July 20, 1910, she received 0.4 gm. salvarsan in neutral suspension. By August 5, regression of all lesions had occurred, but returned October 18, with visual disturbances and abducens paresis.

Case 3.—Girl, 22 years old, who had been treated for malignant lues, with mercury and iodids and thirty injections of arsacetin and eighteen of enesol. July 6, 1910, the patient received 0.4 gm. salvarsan for gummata of nose and pharynx. September 5, three months later, symptoms of beginning optic atrophy with visual disturbances, sluggish pupils and contracted fields were present.

Case 4.—Man, 28 years old, with lues of five months' duration. Aug. 8, 1910, received 0.45 gm. of salvarsan. October 3, the Wassermann reaction was negative. He returned Nov. 10 with a chorioiditis of the right eye.

Case 5.—Kowalewski,[2] of Berlin, reported the case of a 28-year-old woman, injected with salvarsan in the spring of 1910, for an early syphilid. Rapid improvement. In July symptoms of luetic meningitis and neuritis optica developed. The employment of mercurial inunctions was followed by a rapid cure.

Blaschko[3] reported before the Berliner dermatologische Gesellschaft, Dec. 13, 1910, a second case of neuritis optica which he had observed after injections of salvarsan. He stated that the cases were different from the toxic optic atrophy encountered after atoxyl.

Held, at the same meeting, likewise reported a case of optic neuritis after salvarsan.

Rille,[4] of Leipsic, reported two cases of optic neuritis in association with auditory disturbances after salvarsan, and a third case of auditory disease alone. These will be referred to later.

In the discussion following the reading of Finger's paper, November 18, 1910, before the Royal Medical Society of Vienna, the following cases were reported:[5]

Oppenheim, out of sixty-four cases, observed one case of optic neuritis treated with salvarsan for secondary lues.

Nobl saw no injurious results among seventy-two patients.

Von Zumbusch, out of 300 cases, observed one of optic neuritis, which improved under mercury and then relapsed. A short time before he had seen a similar case which occurred in a patient treated only with mercurial injections.

Dimmer treated many eye lesions, including seven cases of iridocyclitis luetica, with salvarsan, with very good results. In one case there was a recurrence with severe papilloretinitis.

Doerr had uniformly good results in 270 cases.

Carl Stern[6] reports cases of oculomotor palsy after subcutaneous injections of salvarsan. Stern has observed three cases of oculomotor paralysis in 200 patients treated with salvarsan. The patients had negative Wassermann reactions.

Case 6.—Fordyce[7] reports the case of a physician with a digital chancre and secondaries, who received 0.6 gm. of salvarsan Oct. 7, 1910. In November, he suddenly developed a choked disk. Fordyce also reports a similar case which developed while the patient was under mercurial treatment and which was cured with salvarsan.

Case 7.—Schamberg[8] reported the case of a woman, aged 29, who presented herself Nov. 10, 1910, with a general macular eruption of three months' duration, with persistent headaches during this period. Wassermann reaction + + +. November 11, she received 0.45 gm. of salvarsan in neutral suspension subcutaneously. On the following day she said the "misty vision" (of which she had not previously spoken) and the headache had disappeared. Gradual disappearance of the eruption. She returned December 28, complaining of severe headaches, vertigo, vomiting and loss of vision in right eye, with some dimness in left. Dr. George E. de Schweinitz, who examined her, reported choked disk with retinal hemorrhage, and almost no vision in right eye, with beginning involvement of left. She was later vigorously treated with mercury and iodids by Dr. Howard Hansell and on discharge from the hospital was greatly improved, having 20/40 vision in right eye and 20/30 in left.

AUDITORY NERVE DISTURBANCE

Finger reported the three following cases (8, 9, 10):

Case 8.—Man, aged 22. Cutaneous syphilis and periostitis. Aug. 24, 1910, 0.5 gm. neutral salvarsan injected. Next day nystagmus, dizziness, typical falling symptoms; normal hearing. Diagnosis, vestibular nerve disturbance. Complete recovery in a few days.

Case 9.—Man, aged 25. Syphilis of six weeks' duration. Aug. 27, 1910, 0.45 gm. salvarsan injected subcutaneously. Later negative Wassermann. Nine weeks after injection, dizziness and deafness developed. Diagnosis, bilateral labyrinthine deafness. Conditions remained unchanged.

Case 10.—Girl, aged 18. Syphilis of three months' duration. Aug. 5, 1910, 0.45 gm. salvarsan injected subcutaneously. November 3, complained of dizziness and headache. Diagnosis, labyrinthine deafness, dizziness and spontaneous nystagmus. No improvement by Nov. 27, 1911. Wassermann negative.

Case 11.—Dr. H. Frey[9] reported a case of deafness and some vestibular nystagmus in a patient injected Aug. 9, and returning in October with the above mentioned symptoms. He had treated 100 patients with salvarsan.

Rille reported three (12, 13, 14):

Case 12.—Woman, aged 21, with early syphilis. Injected July 7, 1910, 0.45 gm. salvarsan. Four weeks later there developed dizziness, noises and deafness in right ear. Later partial facial paralysis. Up to Nov. 15, 1910, some improvement.

Case 13.—Girl, aged 18. Salvarsan, 0.45 gm., injected July 10. Oct. 10, headaches and dizziness, and on following day right-sided facial paralysis, followed in three days by optic neuritis. Under mercurial inunctions, the facial palsy and other symptoms disappeared. Patient cured.

Case 14.—Man, aged 32. July 7, injection of salvarsan. In middle of October, high-grade double labyrinthine disease developed.

In the discussion following the reading of Finger's paper, the following cases were reported:

Kren examined eighty-nine of 140 patients treated with salvarsan in Riehl's clinic. In one case two months after the injection there was a slight labyrinthine impairment of hearing, with a negative Wassermann.

Urbantschitsch examined the ears of sixty patients treated by Finger, Riehl and Ehrmann and observed five cases of suppression of function of the vestibular nerve, which developed shortly after the injection and rapidly disappeared.

Matzenauer had one case of auditory disturbance in 126 cases.

Ullmann treated sixty-two patients without any complications.

Rusch observed a case of severe involvement of the auditory nerve two months after the use of salvarsan.

Finger reported one additional case of auditory nerve disease, Beck a case of one-sided deafness from the clinic of Zumbusch and one case of vestibular disease was seen by Zechmeister of Sarajewo.

Alexander,[10] of Vienna, reports the following case (15) of a patient treated by Nobl:

Case 15.—Woman, aged 30, contracted syphilis in the spring of 1910, received injections of mercury and at the end of July complained of deafness and tinnitus in right ear. This was later cured. In October trouble with left ear began, which was treated with salvarsan. In November left ear grew worse and ended in complete deafness.

Case 16.—Dr. George L. Richards,[11] Fall River, Mass., refers to two patients of Dr. Daniel Kaufman, who had deafness and labyrinthine symptoms some time after injections of salvarsan. Wassermann positive. Under mercurial injections, the symptoms were improving.

Case 17.—Zeissl,[12] of Vienna, saw a patient who developed facial palsy and tinnitus. The patient received salvarsan intraglutealiy August 7. November 7, the facial palsy developed.

Case 18.—Paul Lazarus[13] had a patient in whom left-sided labyrinthine disease with tinnitus and deafness developed three days after an injection. In some days this disappeared.

Von Zumbusch found in the literature among 7,000 cases of patients treated with salvarsan in twenty-five clinics, nine cases of auditory nerve disturbance. All were cases of syphilis between the second and the seventh month. In most cases the Wassermann reaction was negative.

There are doubtless other cases of optic and auditory neuritis that have been reported, which have escaped my search. While the detailed references to these cases give perhaps an alarming impression, it is perhaps well to state that the entire number of cases of optic and auditory disease here abstracted is not over twenty-five.

EHRLICH'S COMMENTS

In September, 1910, Ehrlich[14] addressed an inquiry to a large number of clinicians, and determined that not a single case of blindness had occurred among 8,000 patients treated with salvarsan. Since that time one case of retinal atrophy has occurred (Case 3 of Finger), and this patient had had almost a year's prior treatment with arsenical preparations, such as arsacetin, enesol, etc. Ehrlich believes that a hypersusceptibility to arsenic was thus established. A large number of observers including Deutschmann, Gross, Havan, Ogersheimer, Römer, Schanz, Wechselmann (1,400 cases) and Seeligsohn have reported good results in the treatment of luetic ocular conditions. They did not observe any bad effects even in optic atrophy. In syphilitic retinal conditions, splendid results were often obtained. Ehrlich states that salvarsan itself has no injurious effects on the eye.

In regard to auditory disease, Ehrlich made an inquiry of twenty-five clinicians who had treated 7,000 patients with salvarsan: but nine cases of auditory nerve disturbance had been encountered.

LUETIC OPTIC AND AUDITORY NEURITIS BEFORE THE USE OF SALVARSAN

A careful study of the reported cases of optic and auditory trouble following the use of salvarsan leads convincingly to the conclusion that all, or nearly all, of these cases were instances of syphilitic neuritis or *Neurorecidiven*, as they have been called abroad. In proof of this is the fact that many have been improved or cured by mercury and the iodids or a second dose of salvarsan. The important question is whether the salvarsan employed has been a determining factor in their development.

ARE CRANIAL NERVE INFLAMMATIONS COMMONER AFTER SALVARSAN THAN AFTER THE OLD TREATMENT OF LUES?

On this question there is difference of opinion. The known injurious effects of atoxyl and similar substances on the cranial nerves led Ehrlich at the outset to warn against the use of salvarsan in optic nerve conditions. With increasing experience he became convinced of the harmlessness of the new remedy.

Finger, Alexander, Rille and others feel that cranial nerve complications are more commonly seen now than under former methods of treatment. Professor Alexander, the Vienna otologist, states that in the course of six years before salvarsan, he had seen only twelve cases of ear disease in the early stages of syphilis. According to him, acute neuritis of the auditory nerve in early syphilis is very rare.

On the other hand, Professor Urbantschitsch, of Vienna, had previously called attention to disturbances of the optic and auditory nerves after the use of soluble mercury salts.

Jansen, of Berlin, stated to Ehrlich that auditory nerve trouble is by no means rare in recent syphilis. He had obtained further improvement from second injections of salvarsan in such cases.

Paul Lazarus[15] says that latent vestibular disease in luetics is commoner than is believed.

Kreibich[16] saw in Graz in one year, four cases of luetic recurrence affecting the auditory nerve, before the introduction of salvarsan; in Prague in four years he had seen only two cases.

Benario, of Frankfort,[17] in view of Finger's reports, searched through a part of the case reports sent to Ehrlich, and utilizing only those with exhaustive data, found seven cases (Cases 19 to 24, and 28) of auditory nerve disturbance before the use of salvarsan. In addition, data concerning three other cases (Cases 25, 26, 27) were communicated in letters. All were early cases.

Case 19.—Woman, aged 23. Mercury salicylate injections. Complete deafness in one ear and partial in other; oculomotor palsy. After two injections of salvarsan, complete cure.

Case 20.—Man, aged 27. Mercurial treatment. Facial and auditory palsy three months after infection. After salvarsan, disappearance of symptoms in three days. Brilliant result.

Case 21.—Woman. Received forty mercurial injections; six months after infection, facial palsy, almost complete deafness, diplopia and ptosis. (Disappearance of facial palsy under mercury). After salvarsan, improvement in hearing and disappearance of diplopia.

Case 22.—Man, aged 22. Forty mercurial injections. Five months after infection, right-sided facial palsy and deafness in right ear. No improvement in hearing after salvarsan.

Case 23.—Man. Six injections of insoluble mercury salts. One month after infection almost complete deafness. Following use of salvarsan, gradual restoration of hearing to normal.

Case 24.—Woman, aged 39. Eighteen injections of salicylate of mercury. About three months after infection, partial deafness in both ears; could not hear conversation Ten days after salvarsan, great improvement. At time of last report, hearing normal.

Case 25.—Woman, aged 34. Three months after infection, partial deafness. After use of salvarsan, rapid improvement. At present, hearing normal.

Case 26.—Woman, aged 30. Eight mercury injections. Several months later, labyrinthine disease (tinnitus, partial deafness, vertigo). Cure under mercury.

Case 27.—Complete deafness during secondary stage. Could not hear pistol shot. Mercury used without results. Improvement under salvarsan. Can now hear loud conversation.

Case 28.—Reported by Professor Unna, of Hamburg (Unna: *Monatsh. f. prakt. Derm.*, 1910, li, No. 12). Musician developed during the remission period impaired memory, failure of concentration, tinnitus and impaired hearing. Patient had previously had mercurial treatment. After an injection of salvarsan, all the symptoms disappeared except the one most important to the patient, namely, his deafness, but this was gradually cured in the course of a number of weeks.

Becker,[18] in 1907, found among 200 syphilitics in the early period, 6 per cent. of cases of optic neuritis.

Fehr, of Berlin, examined the eyes of a large number of Wechselmann's patients and stated that before treatment he found 2 to 3 per cent. of cases of neuritis, choked disk and retrobulbar neuritis without subjective disturbance.

Wechselmann says that among more than 1,400 patients treated with salvarsan, he did not observe any ocular trouble, although ophthalmic examinations were pretty generally carried out. In two cases, there were temporary "floating specks."

RESULTS OF TREATMENT

In a considerable number of cases, the optic and auditory trouble has improved or cleared up under the use of antisyphilitic remedies. Patients with neuritis occurring spontaneously or after mercury have often done well under salvarsan or further mercurial treatment, and in cases occurring after the use of salvarsan the patients have often improved under a second dose or under mercury and the iodids.

Marshalko[19] says beginning optic atrophy is no contra-indication to the use of salvarsan if the drug is otherwise indicated. After consultation with Professor Imre, director of the Eye Clinic in Klausenberg, Marshalko injected a number of such patients. No injury occurred in any case; indeed, the process became stationary in some, and in others there was apparent improvement. These results prove that the neuritis is not a primary toxic condition, but a fresh syphilitic involvement, a conclusion most pertinent to this discussion.

Another point of interest is that in all or nearly all of the cases reported the patients have been in the early stage of syphilis, between the second and eighth month after infection. This is additional evidence of the luetic nature of the process.

Furthermore, all of the cases have occurred after the subcutaneous or intragluteal use of mercury and none, so far as the reports go, after the intravenous administration.

This is most suggestive in view of the fact that the intravenous administration is the most intensive method of treatment. Furthermore, among those clinicians who have used the largest doses of salvarsan (Gennerich, Duhot, Weintraud) neuritic disturbances have not been observed.

THEORIES AS TO THE CAUSE OF THE COMPLICATIONS

Abstracting the views of various men, the following propositions may be formulated:

1. The optic and auditory nerve trouble is syphilitic in character and may occur spontaneously or after mercury or salvarsan, and is unrelated to the latter (Ehrlich).
2. These complications are syphilitic, but in some way related to the administration of salvarsan, perhaps due to the traumatic effect of the drug on the nerves (Finger, Rille et al.).
3. When occurring early, it is suggested that the complications may be an effect analogous to the Herxheimer reaction (Urbantschitsch, Pincus, et al.).
4. It is believed by some observers that the introduction of salvarsan in "depots" in the subcutaneous or muscular tissues, where much of it may remain and undergo chemical change, may be responsible for a toxic effect on nerve structure.
5. I believe that an important factor in many cases in the production of the neuritic complications has been the cessation of treatment after a single subcutaneous or intramuscular dose of salvarsan; so much was anticipated concerning the radical curative effects of salvarsan that no subsequent treatment was given for months. In sixteen cases in which the dates of the administration of the salvarsan and of the development of the neuritis are given, between two and three months elapsed in twelve of the cases. In a very few cases, it must be admitted, the complications have arisen within a few days. In these cases it is suggested that the condition may be analogous to the Herxheimer cutaneous reaction. If the neuritic manifestations are commoner after salvarsan than after mercury, the discontinuance of treatment may account for the difference, for mercurial treatment is continued for a much longer period of time. If subcutaneous and intragluteal injections are administered they should be followed in a short time by other treatment. It is reasonable to believe that this would in large part prevent the neuritic inflammations, as they are as a rule favorably influenced by the readministration of treatment.

A PLEA FOR THE INTRAVENOUS USE OF SALVARSAN

Not only is the intravenous administration of salvarsan infinitely less painful than the subcutaneous or intragluteal methods; not only does it obviate the liability to tumefactions, abscesses, and necrosis of tissue, but it is decidedly more effective.

Schreiber, of Magdeburg, who has used intravenous injections, and at times reinjections, in over 800 cases, has observed only four recurrences. In the early period when he employed intramuscular injections, he encountered seventeen recurrences out of a relatively small number injected.

Writing in October, 1910, Schreiber[20] said that in over 400 patients treated intravenously, he had observed no untoward effects on the eyes.

A. Frankel[21] states that an intravenous injection cured a patient with tertiary lues of the skin whose case had not been influenced six weeks before by an intramuscular injection.

In my own experience, I have found the intravenous injections to be distinctly more efficacious than the treatment by other routes. To be sure, subcutaneous or intragluteal injections will often effect a disappearance of the lesions, but this does not teach us the extent to which the underlying disease has been influenced.

It is proved that recurrences are much less early and less frequent after intravenous injections than after administration by other methods. It appears also that inflammations of the cranial nerves have only occurred after intramuscular and subcutaneous injections, therefore, the superior advantages of the blood route over other methods seem to be established.

The theoretical consideration that elimination is more rapid after intravenous injections should not weigh as an argument against the determined clinical results. Arthur Bornstein[22] has shown by experimental research on animals, that the largest part of the dose of salvarsan administered intravenously does not remain free in the blood, but is deposited in the liver, spleen and kidneys.

CONCLUSIONS

1. Inflammation of the optic, auditory, facial and other cranial nerves has developed in a minute percentage of cases after the use of salvarsan in syphilis.
2. The same complications may occur spontaneously or after the use of mercury.
3. Whether the incidence of such neuritic complications is larger after salvarsan than after mercury is a mooted question, on which foreign specialists are not agreed.
4. These inflammations have occurred almost exclusively in cases of recent syphilis.
5. They appear to have occurred exclusively after intramuscular and subcutaneous injections and not after the intravenous administration.
6. Optic and auditory neuritis have in many instances cleared up under a second dose of salvarsan or under mercury and the iodids.
7. Most of the cases of neuritis have occurred two to three months after a single injection. A risk is incurred in discontinuing antisyphilitic treatment for a long period in early syphilis, after a single injection of salvarsan, particularly when given subcutaneously or intramuscularly. It would be, of course, likewise dangerous to cease treatment after brief mercurial administration.
8. The intravenous method of treatment has many advantages over the treatment by other routes.

1922 Spruce Street.

Intestinal Surgery.—The present-day success of intestinal surgery is due largely to careful observations of conservative clinicians. Great progress was made when surgeons had a fair understanding of bacteriology and biology and a clearer conception of the vital processes in connection with all lesions within the abdomen. The part played by the peritoneum in connection with infection within the abdominal cavity and the repair of wounds of the intestines is now known and has greatly modified surgical technic. The study of phagocytosis, antibodies and opsonins in the blood has enlarged the surgical horizon. The elimination of all possible bacteria from the alimentary canal previous to the operation and the strict observance of asepsis at the time of operation has greatly increased the possibility of success in intestinal work.—A. E. Benjamin, in *Lancet-Clinic.*

IMPERMEABLE CARDIOSPASM SUCCESSFULLY TREATED BY THORACOTOMY AND ESOPHAGOPLICATION

WILLY MEYER, M.D.
NEW YORK

The operative method carried out in the case described below may be of interest, and perhaps also of some practical value.

History.—R. M., a woman, aged 47, sick for fifteen years with typical symptoms of cardiospasm, with frequent regurgitation, became worse gradually; she was treated by a number of physicians, but the cardia was never dilated; of late the patient had been unable to swallow anything. The patient entered the medical division of the German Hospital (Dr. M. Einhorn). Neither sounds nor dilator could be made to pass into the stomach; they evidently slipped sideways into an esophageal pouch, which rested on the diaphragm. Metal sounds passed down a distance of 17¼ inches from the teeth before they met resistance (14 inches being the normal distance in grown persons); flexible tubes could be made to pass 1½ inch further down. Rectal feeding had to be resorted to, but soon had to give way to a gastrostomy according to Kader's method (Dr. M. Rehling). Operation was well borne, and the patient was instructed to chew her food, but instead of swallowing it, to spit it into a receptacle partially filled with some kind of nourishing fluid, from which it was then poured into the stomach. In spite of this she did not gain and asked to be relieved by operation.

The proposition made to her to let me try first to pass the contracted cardia with the help of the esophagoscope was refused, and was not particularly pressed in view of the unfavorable results obtained by others in cases of such long standing. An attempt was made, however, to pass the cardia from below, for which purpose the stomach was washed clean and direct gastroscopy performed with the electric cystoscope introduced through the gastric fistula. Owing to the lack of proper landmarks I did not succeed in definitely locating the cardia, an experience I had frequently had before in similar cases; nor was I able to pass a ureter catheter by means of the ureter catheterizing cystoscope, although at one time a metal probe had been introduced through her mouth down to the obstruction, and this, as well as the ureter cystoscope, had been made visible with the help of the fluoroscope, the *x*-ray tube being placed at the back of the patient for the purpose of locating the cardia. The failure was evidently due to the fact that the cardia proper could not be pressed forward by the sound.

After consultation with Dr. Einhorn I decided to perform thoracotomy under differential pressure and, if the diffuse esophageal pouch demonstrated by the *x*-rays should be found to be due to cardiospasm and not to a carcinoma which might have developed on the basis of an old ulceration, I would then try to reduce its diameter by esophagoplication. Excision of a large ellipsoid piece of the entire length of the esophageal wall with immediate suture would have been a more radical step. However, such an operation would have involved greater risk than it seemed wise to take in view of the patient's greatly reduced condition; she weighed 87 pounds.

Operation.—May 31, 1910, operation was performed under positive differential pressure by means of the positive chamber in use at the German Hospital since April, 1909. Stomach lavage was first performed, the gastric tube removed and the fistula packed with iodoform gauze and covered with zinc adhesive plaster. The patient was given a hypodermic injection of morphin ⅙ gr., atropin 1/100, and, by hypodermoclysis, 1,000 c.c. saline solution. Anesthol anesthesia was employed, with two narcotizers in the chamber, with oxygen tank and esophageal sounds. The thorax was put on the stretch by means of the new operating-table for thoracic surgery elsewhere described,[1] a curved incision was made over the sixth to the tenth ribs, exactly corresponding in direction with the lower part of the typical Schede incision, and a skin and muscle flap raised. An incision was then made in the eighth intercostal space. The lung was superficially injured on dividing the pleura because of a total adherence of the lung to the costal pleura. Careful blunt dissection was done and the incision lengthened anteriorly and posteriorly. The wound was then gently separated and the rib-spreader inserted, but, in order to avoid rib fracture, wide separation was not forced. Separation of the lung from the costal and diaphragmatic pleura posteriorly proved easily feasible. A number of double ligatures, with divisions between, were needed for firm ligamentous bands. When the lung was pushed off from the anterior mediastinum it tore at two places, which were temporarily covered with moist gauze sponge. When the loosened lung (which remained adherent inwardly) was pushed upward and inward, away from the diaphragm and aorta, a large pear-shaped swelling was seen, corresponding to the lower end of the esophagus. This evidently was the sac in which the instruments had been caught. The overlying pleura was split, the pneumogastric nerves made out and thoroughly separated from the esophagus on either side for fully five inches. The sac was loosened all around with both hands until the finger-tips met posteriorly at the spinal column. The cardia was palpated through the diaphragm and found not infiltrated and could be pulled into the thorax for a distance of about one inch without opening the abdominal cavity, a phenomenon also observed in previous cases. The cardia was surrounded by the finger, then by a piece of twisted gauze, the ends of which were clamped. This gave a good hold. The tip of a long flexible sound now introduced into the esophagus was felt in the pouch posteriorly and laterally over the spinal column. It was lifted by the left hand, which rested behind the esophagus, and met by the right in front which guided it toward the cardia, the latter resting on the gauze handle. The sound passed the cardia nicely, its upper end being gently pushed by the narcotizer. This proved conclusively that the cardia was permeable to instruments.

The sound being withdrawn, a double esophagoplication was done, the same as is done when performing gastrotomy according to Kader. Interrupted silk sutures, flat curved needles and the indispensable "Küster's swan" were used,[1] care being taken not to penetrate the esophageal wall and not to include the pneumogastric nerves. Meanwhile an intravenous injection of saline with 20 mm. of adrenalin had become necessary. The esophagus was then dropped back into its normal place and the initial lung incisions and tears stitched with a straight round needle threaded with fine silk, grasping just enough of the pleura to close the wound. Suture of the rents near the mediastinum were technically difficult or impossible and a small flap of parietal pleura just hanging handy was stitched on to the lung to cover one of the rents. Air was thought to be heard passing out of the lung now and then. Closure of the thoracic wound was then undertaken. Two pericostal silk sutures, tied, held the ribs in proper apposition until three double chromicized catgut retention sutures, made to pass through drill-holes in the middle of the lower rib and surrounding the upper one were tightened. Then the silk sutures were cut and removed. The external wound was closed with continuous catgut sutures and the dressing applied. The patient was removed from cabinet and returned to bed; pulse was 108; stimulation was employed.

Postoperative History.—On the following day at noon there was cyanosis and dyspnea, a pulse of 140 and increased respiration. Diagnosis: compression of lung by fluid or air, which latter, it was thought, might have escaped through the pulmonary tear that could not be sutured. To make sure of this, the patient was brought back to the cabinet and the pressure turned on, with everything ready to reopen the wound in case of increase of dyspnea, which would indicate the presence of a pressure pneumothorax. Fortunately, this did not happen, and, as the patient felt comfortable under differential pressure and complained of difficulty in breathing the moment it was stopped, she was left in the apparatus for almost ten hours, food being given frequently through the tube which had been reintroduced through the gastric fistula. When the head was removed from the chamber at 9 p. m. and the patient placed in an upright position, her lips were red as before, and pulse unchanged. She was then brought back to her bed and went on to recovery.

---

[1] Ann. Surg., July, 1910, p. 40.

Interesting points during convalescence were:

1. Accumulation of about one pint of turbid sanguinolent serum, which necessitated drainage on the twentieth day after operation; rib resection was done under cocain, making use of the lowest part of the curved skin incision.
2. A hematogenous infection of the right (movable) kidney, with perinephritis.
3. Spontaneous return of the ability to swallow any kind of food, not only liquid, but also solid.

In the fourth week after operation in this case, sudden dysuria with fever and local tenderness over the right kidney set in; the urine contained pus. As catheterization had not become necessary at any time after operation, and patient had been free from urinary trouble before, we had to diagnose a hematogenous infection. Medicinal treatment was resorted to. Subsequently the infiltration was very much reduced, the urine clear and bilaterally normal, as proved by ureteral catheterization. Evidently a cortical abscess had perforated into the perinephritic fat.

In the third week after the operation, during a very hot night, the patient drank a whole glass of water, passing it into the stomach without any trouble. So far she had been fed exclusively through the gastric fistula and had been warned not to make use of the esophagus for feeding purposes. One week later semisolid, and soon thereafter, solid food passed through the cardia without any difficulty. This favorable condition continued unchanged since the middle of June, 1910, that is over six months, and may, therefore, be considered a permanently established feature. Later, six and a half months after the operation, the patient was absolutely well.[2] The wound remained definitely closed since the middle of July, 1910. The patient swallows her food with perfect ease; there is never any difficulty in deglutition, nor the slightest tendency to regurgitation. She weighs 118 pounds against 87 pounds before the operation, and is gaining steadily. At times there was a slight rise of temperature due to the still present perinephritic infiltration.

The cure of the impermeable cardiospasm in this case seems to have been due, first, to the forcible separation of both pneumogastrics from the esophagus, tearing the many tiny nerve fibers that enter the muscularis of this organ on either side; second, to the artificial reduction of the circumference of the pouch.

It had been the intention to sound the esophagus soon after the operation and if the tube passed the cardia, to try the dilator and distend the contracted muscular ring. This became unnecessary, as the desired condition set in spontaneously.

A direct operative attack on the cardia for spasm was first undertaken by the late von Mikulicz. He stretched the cardia with forceps through a gastrotomy wound. Wendel performed osteoplastic resection of the costal arch, following this by a plastic operation according to pyloroplasty by the Heinecke-Mikulicz method.

As an after-effect of thoracic operations on the human subject, it has been a frequent observation by other surgeons, as well as myself, that an effusion of a serous or serosanguinolent fluid takes place into the pleural cavity operated on, and that aspiration of this fluid does not overcome the dyspnea. In the majority of cases the accumulation of this fluid has been the cause of death, or at least has materially contributed to the death. This fact appears to justify the conclusion that the future of thoracic surgery rests on the development of a proper after-treatment. I have thus expressed myself in various medical societies and note from a recent article of Wendel's that he has come to the same conclusion. Air-tight closure of the thoracic cavity whenever possible after the intrathoracic work is finished, has been the advice given by other workers in this field. In the light of the experience gained in this case, however, as well as that which I have had in several other thoracic operations, it seems to me that this dictum may have to be changed or modified. Instead of using air-tight closure, I think it will be necessary for us to learn how to drain the thorax during the first twenty-four hours, perhaps even thirty-six or forty-eight hours, after a severe thoracic operation, without incurring the dangers of a pneumothorax.

Several ways of fulfilling this desideratum come to mind. One of them is the use of the chamber. The head of the patient is kept within the chamber under pressure and tubes drain the thoracic cavity or cavities into the aseptic dressing which has been applied. Relays of assistants and nurses attend to the needs immediately after operation.

Another procedure would be to apply a sort of valve dressing permitting of drainage.

Wendel, in speaking of operations for cancer of the cardia, expresses the intention of draining internally into the abdomen or through the abdomen to the surface after a combined thoracic-abdominal operation.

As soon as the patient has satisfactorily passed the first twenty-four to forty-eight hours and the pleura has ceased to secrete, the drain or drains may be withdrawn and, under increased differential pressure, the wound covered with rubber tissue and a large dressing, closing the thorax air tight.

Should equally favorable results be obtained with the above-described procedure in subsequent similar cases a new method of radical cure of impermeable cardiospasm by the most direct route would then be established.

Note: Since I wrote the above, the patient has passed through a severe attack of influenza, January, 1911. Shortly after she had recovered from this attack, the scar resulting from the empyema reopened in one place and gradually an esophageal fistula established itself, producing some leakage through the fistula. Evidently one or more of the silk sutures in the esophageal wall caused a perforation, swallowing meanwhile continuing with perfect ease. This experience teaches that chromicized gut should be used rather than silk for sutures and ligatures within the thorax, if we are unable to guarantee aseptic wound healing.

700 Madison Avenue.

---

[2] The patient was presented before the New York Surgical Society, Nov. 23, 1910.

CARDIOSPASM

REPORT OF A CASE: TREATMENT BY OPERATION AND SUBSEQUENT DILATATION

J. H. IDEN, M.D.

Surgeon, U. S. Navy, on duty with the U. S. S. *Washington*

There is little about cardiospasm found in text-books, and until recently almost nothing in periodical literature. Within the past few years, however, a great deal of attention has been attracted to it, especially in Germany, and the facts stated by careful observers, there and elsewhere, who have been on the alert to detect cases of cardiospasm, would seem to justify the assertion that many of us are overlooking some, and perhaps many, patients affected with this condition.

H. S. Plummer of St. Mary's Hospital, Rochester, Minn., reported forty cases.[1] Only four of his patients were treated by operation, the simpler method of dilatation being sufficient to effect a cure.

---

[1] Plummer, J. A.: The Journal A. M. A., Aug. 15, 1908, p. 549.

It might be well at this point to define cardiospasm. *Cardiospasm* is a condition in which there is spasm of the circular fibers of the cardiac orifice or esophageal opening of the stomach; dilatation and retention of food in the esophagus, with periodical regurgitation. This, of course, describes a fully developed case.

The causes of the disease, as collected by Plummer in his full and valuable paper, are as follows:

"First, primary cardiospasm (Meltzer); second, primary atony of the musculature of the esophagus (Rosenheim); third, simultaneous presence of cardiospasm and paralysis of the circular fibers of the esophagus, brought about by paralysis of the vagus (Kraus); fourth, congenital disposition (Fleiner, Zenker, Luschka, and Seivers); fifth, primary esophagitis (Martin); and, sixth, kinking at the hiatus esophagi."

This observer in discussing the causes of the disease says:

> In the study of a considerable number of cases the almost invariable history of a spasm at the onset, followed at a later period by the evidence of dilatation—that is, retention of food in the esophagus—is most convincing evidence that the spasm precedes the dilatation, and primary atony is relatively a rare condition.[1]

While it is true that a spasm of the cardia may be due to, or associated with, lesions of the esophagus or stomach, I do not believe that it is the cause in many cases. Certainly no lesions of these organs, and no history of their previous existence, were found in the case about to be reported.

Swallowing is divided into three acts. I shall consider only the third, in which the food passes through the esophagus. Every part of the tube, as it receives the morsel and is dilated by it, is stimulated to contract: hence an undulatory or peristaltic contraction of the esophagus occurs. If we suppose the bolus to be at one particular place in the tube, it acts stimulatingly on the circular fibers behind it and inhibitingly on those in front; the contraction, therefore, squeezes it into the dilated part in front, where the same process occurs, and this travels the whole length of the tube.[2]

The esophagus does not contract in sections, as was once thought, but there is a peristaltic wave. It is usually thought that the sphincter of the cardia is tonically contracted.[3] However this may be, it is certain that contraction of the esophagus is due to the vagi; and if it is true that these nerves supply the esophagus with motor, and the cardiac sphincter with inhibitory fibers, any disturbance or degenerative changes of these nerves would produce cardiospasm. "Division of both pneumogastric nerves gives rise to paralysis of the esophagus and stomach and firm contractions of the cardiac orifice. These nerves, therefore, normally supply the esophagus with motor, and the cardiac sphincter with inhibitory fibers. If food is swallowed after these nerves are divided, it accumulates in the gullet and never reaches the stomach. While it is true that peristalsis is an inherent property of the muscle, which is normally controlled by nervous agency, it must be remembered that the nervous control is especially marked in the esophagus. . . . It seems probable that the peristaltic contractions of the esophagus, to be efficient, must be supported by nervous influences from outside. In this respect the esophagus is different from the remainder of the alimentary canal."[2]

REPORT OF CASE

History.—M. S., aged 18, unmarried, a farmer, was seen by me Jan. 20, 1910, at the request of his physician. His father had died thirteen years previously with "white swelling" of leg; his mother, brothers and sisters were living and in good health. The patient had measles in early childhood; otherwise had never been ill, and had enjoyed perfect health until the present trouble began, in 1906. He had always been in the habit of eating his meals very rapidly. One morning in 1906, having just finished eating, he suddenly experienced a choking sensation, with considerable pain, in the region of the cardia. He described it by saying that it felt as though part of his breakfast had stuck in his chest. In a short time this passed off and he ate his dinner, about three hours later, without discomfort. Attacks occurred after this about once a week, gradually increasing in frequency, with marked difficulty in swallowing. At first he was able to force all the food into the stomach, but finally part of it seemed "to stop just below the lower end of the breast-bone." The condition gradually grew worse until it would take him from two to three hours to get any considerable amount of food into the stomach. After filling the dilated esophagus, part of the food was forced into the stomach and part was regurgitated. The patient had been treated by a number of physicians without any relief whatever; was compelled to stop working on account of weakness, and because most of his time was taken up trying to eat; had lost weight slowly at first, but very rapidly of late. For the previous month or two the patient had devised a method of getting a certain kind of food into the stomach, and on this alone he had subsisted. A syrupy mixture was made by mashing a few crackers and then adding sugar and water. This was eaten, but did not enter the stomach. After this the patient would swallow solid food until he was conscious that he would regurgitate it if more were taken; then, after taking a sip of weak coffee, he would take a deep inspiration, close his mouth, shove his head forward and with slow pumping motions force the syrupy mixture into the stomach. When this method was successful he had a distinct sensation of food entering the stomach; but when it did not, the air compressed in the throat and mouth, rushed back through his mouth and nose. At other times some of the air gained entrance into the larynx, giving rise to coughing, such as is caused when one has, as is said, "swallowed the wrong way." The solid food would remain in the esophagus until regurgitated, or could be, and usually was, washed out immediately after passage of the syrupy mixture into the stomach. Living in the country, where modern plumbing facilities were not at hand, he had learned that the most convenient method of doing this was to lie on the ground beside a running stream, and after taking several swallows of water allow it to regurgitate and be carried down the stream. In this way he would wash all the retained food from the esophagus.

The difficulty of getting food into the stomach could easily be seen when the patient ate. He could easily swallow liquids or solids up to the amount of two and one-half glassfuls, or about 20 ounces, when, as he stated, he could swallow no more without regurgitating it. This material left in place for three hours could be regurgitated without difficulty, by simply stooping over until all ran out. Of course, during this time a certain amount of the liquid would seep through the cardiac orifice by gravity.

Physical Examination.—The patient was a thin but otherwise healthy-looking youth, about 5 feet 10 inches in height, and weighing 109 pounds. No abnormality could be detected by ordinary examination; urine normal; blood deficient in hemoglobin.

Diagnosis.—The two cardinal symptoms, the difficulty of getting food into the stomach, with frequent regurgitation of food and mucus, at once called attention to some obstruction above the stomach. After the history of the patient was taken, syphilis and the swallowing of caustics and foreign bodies excluded, and a general examination made, a stomach-tube was stiffened with a large esophageal bougie and introduced. The distance from the incisor teeth to the obstruction was measured and found to be 42 cm. At times the tube would pass through the cardia, not very easily on gentle pressure; at other times with great difficulty, if it could be made to pass at all. The times when it could be made to pass were very few, and then the end of the tube had to be held against the cardia for some time and considerable pressure used. That it could be made to enter the stomach, however, was proved by the entirely different character of food obtained, which showed hydrochloric acid present, and which contained partly digested food with a sour odor. After having thoroughly washed out and entirely emptied the esophagus, a thorough examination was made with the esophagoscope, which revealed no evidence of a diverticulum, new growth, ulcer, fissure or foreign body; the mucous membrane appeared normal, the esophagus large and the walls rather flaccid. Twenty ounces of potato soup containing 20 per cent. of bismuth subnitrate was given and a radiograph of the chest was made. This showed a greatly dilated esophagus, tapering to a point near the cardia. Examination of the contents of the esophagus, two days after eating meat and hard-boiled eggs, showed large pieces of undigested meat and egg and considerable mucus; there was no odor; the reaction was alkaline. There was no evidence of pepsin or hydrochloric acid. From this there seemed to be no doubt that the contents removed were from the esophagus only. Photographs of pieces of solid food were taken. The patient complained of dyspnea and slight discomfort when the esophageal sac was full, which entirely disappeared when the contents were regurgitated, or washed out.

---

[2] Kirk's Handbook of Physiology, Ed. 21.
[3] Gray's Anatomy, Ed. 17.

As there seemed to be no doubt as to the diagnosis, it was decided to operate, first, in order that the patient might be fed through a tube fastened in the stomach, thereby permitting the patient to gain strength and weight; second, to allow the dilated esophagus complete rest and to contract as much as possible; and third, that the sphincter might be stretched at the same time that gastrostomy was performed.

Operation.—Jan. 28, 1910, gastrostomy was performed under ether. Witzel's method was used, except that the incision was made longer than four inches, as described in his operation. After opening the peritoneal cavity the stomach was seized, brought out of the wound, and gauze packed around it. An incision was made into the stomach wall large enough to admit the hand. One finger was introduced into the cardiac opening of the stomach and the contraction of the hypertrophied sphincter could easily be felt, resembling the contraction of the uterine cervix before thorough dilatation, preliminary to curettage. Under the control of two fingers a curved intestinal clamp, the blades of which were guarded with rubber tubing, was introduced with some difficulty into the esophageal opening. The blades of the forceps were gradually opened and closed until the cardia was fairly well dilated. No measurement of the distance between the blades was taken; the amount of force used was determined by muscular sense, care being taken not to use sufficient force to tear the esophagus. The forceps was then withdrawn, the opening in the stomach closed in the usual way, except for a hole large enough to introduce a tube with diameter equal to a number 25 French bougie. The operation was then completed according to Witzel's method.

Subsequent Treatment and Course.—Nothing worthy of note occurred immediately after the operation. Rectal alimentation was not resorted to, the patient being fed through the tube in the stomach by introducing a funnel and removing the clamp from the tube. For the first twenty-four hours nothing was given except normal saline solution, by proctoclysis, to relieve thirst. On the ninth day the superficial sutures were removed. The wound had healed by primary union and nothing remained except the fistulous opening into the stomach. In a short time the tube was withdrawn from the stomach and introduced through the fistula each time the patient was fed. At the end of two weeks the patient was up and around, and had learned to introduce the tube and feed himself, but he was not permitted to introduce any food into the stomach other than the amount and kind prescribed. During twenty-four hours the patient was allowed 3 liters of milk, 30 gm. of sugar, 60 gm. of cream and 240 gm. of thick potato soup, with 4 gm. of sodium chlorid. Tincture of ferric chlorid in water (30 minims) was also administered. Up to this time the patient had taken nothing by mouth. This diet was prepared as follows: each morning 3 quarts of milk and six eggs were thoroughly mixed, strained through cheese-cloth and put in a cool place, ready for use at regular intervals; 8 gm. of lactose, 8 gm. of sugar and 30 gm. of cream in 270 gm. water were given morning and night. Potato soup was prepared in the usual manner, and to it the sodium chlorid was added.

Regardless of this liberal diet the patient continually complained of hunger and in order to be sure that he did not increase the amount of food allowed, the tube and funnel were kept by Miss Decou, the chief nurse, who prepared his food and saw that he received it at intervals of about two hours, and to whom much credit is due for the boy's progress and ultimate recovery.

I now began to pass daily an ordinary stomach-tube which in a very short time the patient learned to pass himself without the least difficulty. Three weeks after operation the patient had gained eight pounds, felt strong and no longer complained of being hungry.

Dilatation of the cardia was then begun with an esophageal dilator made by cementing a rubber-dam balloon to one end of a non-elastic rubber tube in such a way that the tube just passed through the balloon. The end of the tube was closed with a rubber plug and a number of holes so punched in it that its lumen communicated with the interior of the balloon. A silk bag was fastened over the balloon in order to preserve its shape, when distended, and a second rubber balloon over this to facilitate the passage of the dilator. The dilator was constricted at its center, by tying silk around it, to lessen the tendency for it to slip into the stomach. The distance to the cardia having been previously found and a mark made on the tube, the dilator was then passed and the balloon distended by water forced in by an ordinary Davidson's syringe. The force used was determined by the tolerance of the patient, care being taken not to increase the size of the dilator by forcing in more water after pain was experienced. The principle of this dilator is essentially the same as that described by Plummer, from whose writing I received the idea, though his is more complete and scientific.

During the fourth week the dilatations were continued every other day, and milk and water were given by mouth, most of which readily passed into the stomach. Five weeks after the operation soft diet was permitted, by mouth, and the fistula in the stomach was allowed to heal. The esophageal sac at this time would hold only a few swallows instead of 20 ounces, which was its capacity before operation.

A radiograph showed the esophagus contracted down to nearly normal. From this time on diet was steadily increased in variety, solids being gradually added. The dilator was introduced every few days.

March 22, 1910, the patient announced that he was well and desired to return to his home in West Virginia, and, on being refused, attempted to prove, as so frequently occurs, that the doctors were not so wise as the patient. That night he celebrated a grand feast on fresh pork, potatoes, etc. At 2 o'clock the following morning I was hurriedly called and informed that "Sandy" was dying. On arriving at his room I found him in great pain, frightened, unable to speak above a whisper, abdomen rigid and greatly distended, rapid pulse, flat on his back, bathed in cold perspiration and evidently suffering from acute dilatation of the stomach. A stomach-tube was passed and the stomach was thoroughly washed out, considerable gas being set free and quantities of large pieces of undigested food were removed; in fact, some of these pieces were so large that the stomach-tube often became clogged and had to be removed to be cleared, and then reintroduced. Washing of the stomach gave almost immediate relief. An enema was then given, which was expelled soon afterwards with considerable quantities of gas.

The patient rested well for the few remaining hours of the night and arose late the next morning a sadder but a wiser boy. He stated that he had gone to the hospital kitchen the previous night and had eaten an excessive amount of food and had "bolted" it, fearing that someone would come in before he had finished.

From this time on patient improved rapidly, dilating the cardia himself about once a week.

April 11, 1910, the patient was discharged as cured. He then weighed 150 pounds and was eating all varieties of solid food. After that time I saw the patient twice and there had been no return of the disease.

I cannot assign any definite cause for this boy's trouble, unless it was some disturbance or possible degenerative changes in some of the fibers of the pneumogastric nerves. Again, it will be remembered that the patient was in the habit of bolting his food, which, it seems to me, might have caused a stretching of the lower end of the esophagus, producing a relative increase in the obstruction of the cardia. At the same time the suddenness of the onset, with intervals of absence of symptoms and increasing frequency of attacks, would point to primary spasm of the cardia with resultant dilatation of the esophagus. However this may be, the fact remains that the condition existed and has apparently been cured by operation.

The apparent rarity of this disease, the few cases reported in the literature, and especially the small number that have been operated on, seem to justify the report of this case.

In conclusion I wish to express my appreciation of the valuable assistance given me by Assistant Surgeon George F. Cottle, U. S. N., Miss Decou, Nurse Corps, U. S. N., and Hospital Steward C. P. McGarr, U. S. N., who did the radiographic and photographic work.

THE TREATMENT OF COUGH IN THE CONSUMPTIVE

FRANKLIN M. CLASS, M.D.
Instructor in Applied Therapeutics, College of Physicians and Surgeons, Columbia University
NEW YORK

No symptom in pulmonary tuberculosis is more obvious or more annoying than the cough; now rasping and ineffectual, now milder but continuous, now paroxysmal, or again, remarkably periodical. Each variety has in its turn a rational means for relief, if its cause is but patiently sought. No symptom, probably, in any disease receives more perfunctory or rule-of-thumb therapy than this,[1] at least from others than specialists long skilled in its treatment. And yet by the simplest means the most complete and lasting benefits are often gained.

The types of cough are generally pretty well defined. Thus, in the earlier stages of the disease, most patients complain of the attack of coughing directly after getting out of bed in the morning. Here is where most practitioners err, in starting too soon their sedatives. In nearly every case, this morning clearing-up process, due probably to the change in posture, and to the change in temperature from bed to that of dressing-room, is beneficial. Unless inordinate, followed by exhaustion, or retching, which destroys all appetite for breakfast, this type may best be let alone. Where a moderate amount of secretion has collected over night, and the morning's paroxysm is unique in the twenty-four hours, it is wiser to follow the *laissez-faire* method and conserve the weapons of offense for later use. They are pretty sure to be needed.

Retching is often due to excessive pharyngeal mucus, which, hanging suspended, acts reflexly to set up vomiting. A simple gargle kept beside the bed, and used immediately on waking to cleanse the walls of the pharynx, will often clear up the condition entirely. This procedure worked remarkably well in an adult German woman in the tuberculosis ward of St. Luke's Hospital, who had coughing fits ending in vomiting every morning for months prior to her admission. Some such bland gargle as this may be used:

℞

	gm. or c.c.			
Ac. borici	30	00		℥i
Phenolis		12		gr. ii
Glycerini	8	00	or	ʒii
Aq. rosæ	4	00		ʒi
Aq. dest.	ad 240	00		ad ℥viii

M.
Sig.—Use half and half in tepid water as a gargle.

It is sometimes of advantage to have a comfortably warm dressing-room, into which the patient can step quickly before the temperature of the body, on getting out of bed, is too rapidly lowered.

Most of all, however, should be done through instruction. Mental suggestion may play a real part. The will to hold in check the cough often does more than a prescription. This is not easily inculcated in all the sick, and the end accomplished is often an excellent index of the team-work between doctor and patient. Carefully regulated breathing exercises, mild calisthenics, a series of deep, full inspirations, holding the breath several seconds, etc., are all useful aids.

In the constant dry, nagging cough which lasts off and on all day, a prolonged, systematic search should be made for local causes in the nares, pharynx and larynx. A long uvula is a prime offender.

This has often been carefully pointed out in the standard books, but is still curiously overlooked in many cases. Recently a negro presented himself for a constant cough and spitting of blood-streaked mucoid expectoration. He had a typical infiltration of the right apex; but the inordinate amount of sputum, always streaked with bright blood, demanded an explanation. He had been treated in two other dispensaries with small doses of morphin and absolute rest in bed, presumably under the notion that he was having a mild continued hemoptysis. He was found to have a long, edematous uvula which had irritated the epiglottis till it was twice the normal size. The lower pharynx, and upper larynx were deeply congested, and the sublingual tonsil was enormous. Amputation of the uvula gave him prompt relief, and checked the cough and amount of sputum briskly.

Large turbinates, adenoids, hypertrophied tonsils, and ulcers of the larynx, all demand local treatment. Occasionally cough appears to be due solely to fever. It leaves with the lowering of the temperature. Simple rest in bed generally turns the trick. Again, it is curious how much trouble a small patch of pleuritis can raise. Counter-irritation with mild (1 to 5 or 1 to 6) mustard plasters, repeated every four hours, or better still, strapping the chest for five or six days, is quite efficient. The actual cautery to the subclavicular region, a method formerly employed, is probably not used now by most practitioners; but in some cases it certainly has given relief in the past. The following has been suggested to check excessive secretion in the nasopharynx:

℞

	gm. or c.c.			
Iodini pur	0	1 to 0	3		gr. 2 to 10
Potassii iodidi	1	0 to 3	0	or	gr. 15 to 45
Glycerini	10				℥ 3

M. Sig.—Paint the nasopharynx every day or every other day.

---

[1] Brown, L.: A System of Medicine (Osler), iii, 400.

Often no obvious local cause can be found which will account for the incessant, dry cough. Here again, suitable occupation and stimulation of mental interest should be tried. This can be carried out exceptionally well in sanatoriums or day camps. It is a matter of daily observation, let us say in the theater or lecture room, that as soon as the interest of the audience lags for a few moments, short irritable fusillades of coughing can be heard in all parts of the room. They disappear, as by magic, with renewed excitement or heightened interest. A similar phenomenon can be observed at any time when numbers of consumptives are sitting together. While a visitor or nurse reads aloud from an absorbing story there is complete and grateful quiet. This can be maintained ordinarily at will, by skilfully contriving to occupy the attention and imagination of the sick. It is no small task to keep renewing their flaccid energies, through diverse means of manual employment (puzzles, knitting, the jig-saw, sloyd, etc.).

Another distinct type of cough is that which occurs after eating. This is presumably due, reflexly, to the dilatation and sudden activities of the stomach walls. Its most obvious and most efficient means of control is in small, more frequent meals. The dietary should depend wholly on the general conditions present. But a more concentrated meal repeated as often as the digestion will stand, or the general needs seem to warrant, will obviate the seizure which in a large percentage of cases succeeds in setting up enough vomiting to remove most of the meal. In some cases the assumption of the upright posture for eating, after reclining all the morning, seems to be the cause. It is a good plan to have a tray taken to these patients, and the small meal eaten slowly, avoiding carefully any change in position. A little regulation will serve to keep the day's intake constant, and the calorific value need not suffer.

Sudden changes of temperature, such as that experienced on leaving a warm church or theater, often start vicious attacks of coughing. A slower progress and more careful gradation should be tried. Standing in the entry for a few moments and, protecting the face with a handkerchief until several full inspirations of cooler air are drawn, may prevent the attack.

Again, the local conditions of the patient's work must be looked into minutely. A glance over the records of any clinic will show (especially in the men's histories) a surprising number who have worked for a long time in some dusty pursuit. Of course this should cease, and new employment be found at once. But this change is not always (or indeed often) feasible. Yet through the cooperation of the social service departments and the bureaus for organized charity, a great deal of very real help may be obtained. This simple change in surroundings has been sufficient to produce genuine comfort in a good many cases.

There remain to be considered two other types of common cough, "depending sometimes on the amount of expectoration, sometimes on its quality."[2] Here drug therapy would seem to be clearly indicated. But one must even now approach the Pharmacopeia with caution. Austin Flint[3] taught that "expectorants have no place in the treatment of phthisis. An expectorant remedy that includes nauseants must do harm by interfering with alimentation and digestion. Cough palliatives, containing opiates are allowable only when the violence or frequency of cough causes fatigue and prevents sleep."

A number of methods are advocated to allay hypersecretion. Foremost, probably, stands the use of the perforated inhaler, suggested early in England by Sir W. Roberts of Manchester, and Dr. I. Burney Yeo,[4] and long championed in this country by Dr. Beverley Robinson. This simple apparatus is worn easily by patients, and with judicious periods of rest can be kept on most of the time. At night many wear it without annoyance. There is one real objection here, during the colder months. The warm expired air rapidly condenses and finally drenches the face and pillow repeatedly. This is a very genuine drawback to some, disturbing their rest, and it is far better then to discard the apparatus while sleeping. Its beneficial results are often striking. Recently in an adult, who had a rasping cough and profuse expectoration, the constant use of the inhaler over a period of only six weeks, practically eliminated the cough, greatly reduced the amount of sputum, and cleared the chest of all large, moist râles. He had the added benefit of rest at a day camp.

The principal drugs used on the inhaler are creosote or formaldehyd solution in some combination. The former is used at the Vanderbilt Clinic thus:

℞
Creosoti .....
Chloroformi ..
Spts. vini rect. āā p. æ. [i. e., equal parts of each].
M.

The latter is used in this combination:

℞

	gm. or c.c.			
Formaldehydi (40 per cent.).....	1	00		♏ xv
Chloroformi	2	00		ʒss
Mentholi	0	30	or	gr. v
Ol. pini	0	75		♏ x
Spts. vini rect..................ad	15	00		ad ʒiv

M. Sig.—Use drops x on inhaler.

In Quincke's clinic, the attempt has been made to check excessive secretion by induced hyperemia. The foot of the bed is raised from 9 to 12 inches in the early morning, for two or three hours, and again at night. The patient lies flat on the back, the face turned toward the side.

Kuhn's suction mask[5] is still another means to a similar end. It is a device worn over the nose and mouth, like the perforated inhalers, so constructed by a series of valves that inspiration is forced and at a raised pressure (*Einatmungsbehinderung*), while expiration is accomplished naturally. This has been used by Kuhn, even in advanced cases with cavity formation, without accident. He is enthusiastic over the results.

Creosote, administered internally as recommended by Sommerbrodt, must be watched with great care. Its facility for upsetting the stomach is considerable.

Guaiacol (see Sahli's report)[6] has proved milder and safer. But in very few cases is it advisable at all to medicate much by mouth. The inhaler seems to serve every purpose.

Care must be taken not to dry up the secretions to a point where a thick and viscid sputum, almost incapable of being dislodged, makes miserable a patient who formerly enjoyed reasonable comfort. If this complication occurs, which, as pointed out by Hughes Bennett,[7] happens at times during the process of healing and of drying out a large cavity, a mixture containing the syrup of hydriodic acid may be used cautiously for a few days.

[7] Bennett, H.: Reynolds' System of Medicine, iii, 585.

The nauseants (squills, senega, antimony, ipecac, etc.) may best be wholly discarded.

Preissnitz[8] recommends hot, wet compresses to the throat and neck.

Of the depressants, codein, heroin, and finally, morphin, given in dry, tabloid form upset the alimentary tract, taken all in all, less than when in some syrup-like combination. To codein is given the preference, as it tends less to constipation.

In the terminal, hopeless stage, free use of morphin seems imperative. The general discomfort and suffering otherwise, is appalling. An excellent combination suggested by Dr. H. S. Patterson is this:

℞

	gm. or c.c.			
Morph. sulph.		005		gr. 1/12
Tinct. belladonnæ		30	or	♏ v
Ammon. chlorid.		30		gr. v
Aquæ dest. ad	4	00		ad ʒi

M. Sig.—Such a dose every four hours, if necessary.

Or this of Dr. S. W. Lambert:

℞

	gm. or c.c.			
Ext. opii				
Ext. Belladonnæ āā		12		gr. ii
Chloroformi	1	3		♏ xx
Syrup. tolutani	30		or	ʒi
Aquæ dest.	120			ad ℥iv

M. *Sig.*—*A teaspoonful every four hours, if necessary.*

For a short time heroin (grs. 1/8 to 1/2) seems to work well; but its efficiency is short-lived, and in the very advanced cases soon must give way to morphin, which at last is the sole means of comfort, scant at best.

16 Central Park West.

MENINGISMUS FROM ACUTE CERVICAL ADENITIS AND PERITONSILLAR INFILTRATION

WILLIAM PEARCE COUES, M.D.
Surgeon to the Boston Dispensary
BOSTON

Some unusual features in this case, which so closely simulated some form of meningitis, make it of enough interest to report.

Patient.—A. L., a boy aged 4, was seen June 23, 1910.

Family History.—Father is living and well. Mother has pulmonary tuberculosis, now quiescent. The mother's tuberculosis was first diagnosed while she was nursing this child; she was fairly well advanced in the second stage at this time and undoubtedly had the disease when pregnant.

Personal History.—The patient was an only child and had always been well except for bowel upsets and slight tonsillitis in March. On May 17, a severe attack of coryza came on, and the boy was alternately better and worse for two weeks with more or less constant nasal discharge and slight cough. Then this trouble seemed to clear up and he was all right for a time. The mother had an attack of scarlet fever in May, and the child was exposed on May 6; the mother was promptly isolated. Three weeks after this exposure a slight transient erythema was noticed across the chest, of not more than two or three hours' duration. The boy felt perfectly well at this time. He had eaten fish for the first time in his life the day before this erythema was noticed. After the first week in June the cold which had been much better still persisted. On June 15, the cervical glands were swollen, bilaterally, more on the right than on the left. June 16, 17, 18, the glands were less swollen and the child seemed better at this time. June 19, there was stiffness of the neck on the right side. Temperature 99.6, the tongue coated and the throat clear.

Examination.—June 23, I first saw the boy. Examination showed him to be well developed and nourished. Examination of the heart and lungs revealed nothing abnormal. The throat showed chronically enlarged tonsils; it was perfectly clear, no membrane or exudate was visible. The teeth were good. There was bilateral cervical adenitis. The glands were the size of filberts and slightly larger, discreet, tender, not fluctuant; the skin over them was not reddened. Temperature was 101.2 F. The child felt languid.

Course of the Disease.—Next day, after a restless night, the temperature and pulse were normal. In the morning, the child was sleeping quietly and breathing easily. The glands were somewhat less tender. The condition gradually changed for the worse.

June 25: The child was more listless and weak. Examination showed the pupils equal and reacting to light. No Babinski or Kernig sign was present. Nothing abnormal was found in the examination of the lungs. Examination of the left ear showed the drum slightly reddened. Pulse was 120, temperature 100.2 F. The throat was clear; the tonsils were much enlarged, boggy and pale pink. Gradually the general condition grew much worse. The child's condition was much weaker despite stimulation with salt solution, whisky, caffein and small doses of digitalis.

June 26: The child was apathetic and stupid. The pulse was markedly irregular and somewhat intermittent and would drop suddenly from 120 to 80. The child answered questions only when aroused. Stiffness of the back of the neck was noticed for the first time. At 2 a. m. the condition was alarming. The breathing was stertorous and the child was markedly apathetic, the pulse being weak and irregular. The cervical glands had markedly increased in size. The nose seemed obstructed and the clinical picture resembled that seen in the last stages of nasal obstruction in diphtheria. The child was given antitoxin, though careful and repeated examination of the throat had shown nothing. The result of the cultures taken the day before had not been heard from. Later these cultures showed staphylococcus and streptococcus growth. The child was stimulated with brandy and salt solution and rallied from the acute collapse. The breathing was not quite so obstructed. There was a leukocytosis about 30,000.

In the afternoon, the condition was as follows: General condition about the same as before collapse of early morning, cervical glands markedly swollen, head and neck absolutely rigid, moved with body as a whole, like an iron rod, knees rigid, Kernig sign more marked (a suspicion at a previous examination). Examination of the throat showed a marked bulging shelf over the left tonsil. There was no exudation. Digital examination of the throat was unsatisfactory.

Consultants' Opinions.—The child was seen in consultation by two specialists in children's diseases, one of whom thought, with me, that the condition was tuberculous meningitis. The other thought that there was a possibility of the symptoms being due to the infiltration around the left tonsil and the markedly enlarged cervical glands. These glands had at no time showed fluctuation or softening. It was thought possible that there was pus around the tonsil, but expectant treatment was decided on for a while.

Termination of Case.—That night the child was somewhat better. Next day the shelf over the left tonsil had disappeared; the throat was more easily inspected, the right tonsil was very much enlarged and a condition similar to the shelf-like projection on the left side was present, only not so marked. This quickly subsided. From this time on, the improvement was rapid. The pulse became regular, stiffness of the neck gradually disappeared and the cervical glands became smaller. When the rigidity of the head and neck had almost subsided it was possible to feel enlarged cervical glands as far back as the occiput. Save for a slight irritability of the heart, the boy convalesced quickly, and this irritability soon subsided.

Remarks.—Some weeks after the boy was up and around, there was peeling of the palms of the hands. Desquamation was not noted in any other part of the body. The treatment consisted of digitalis, whiskey, salt solution and caffein. As soon as possible the child was put out of doors for all day, with great benefit.

---

[8] Preissnitz: Quoted by Cornil in Nothnagel's Practice: Tuberculosis, p. 609.

Two interesting points in regard to the case are: 1. Had the child recovered from a mild case of scarlet fever and were the glands sequelæ? None of those who saw the case believe this to be a fact. 2. The fact that the mother was tuberculous, and was undoubtedly so when pregnant with this child, influenced me to a great extent in arriving at a diagnosis of tuberculous meningitis. Dr. Hunter Dunn, one of the consultants, pointed out the possibility of the glands and throat being responsible for all the marked meningeal symptoms, which proved to be the case.

261 Beacon Street.

GOOD AND BAD CORSETS

GEORGE B. SOMERS, A.B., M.D.
SAN FRANCISCO

In preparing a paper on "The Use and Abuse of Corsets" read in the Lane Course of Popular Lectures at Cooper Medical College Feb. 10, 1911, I had the following diagrams drawn. They represent the chief points which seem to me characteristic of the good as contrasted with the bad corset.

While the diagrams are in themselves sufficiently explanatory, and afford a formula for judging the good and bad points of any corset, it may not be amiss to add a few words on the subject in general.

Every practicing physician recognizes the evils resulting from improperly worn or improperly shaped corsets and yet few take pains to investigate a patient's habits in this regard. I venture to say that still fewer have any fixed ideas as to what constitutes a good corset.

FUNDAMENTAL PRINCIPLES

In considering the basic principles on which a corset should be built, the method of support is of first importance.

In that region of the body covered by the corset, the pelvic bones and spinal column afford the best opportunities for rigid fixing of the framework.

At the hips, the space between the crest of the ilium and the prominence of the trochanter extended as a zone about the body, lends itself admirably to tight lacing, without danger of injuring internal organs. Lacing here affords a means of holding the corset firmly in place.

Along the back, following the contour of the spine, we may run a more or less rigid piece forming the rear elevation of the structure.

The strength and supporting properties of the corset rest in this back piece and in the hip zone.

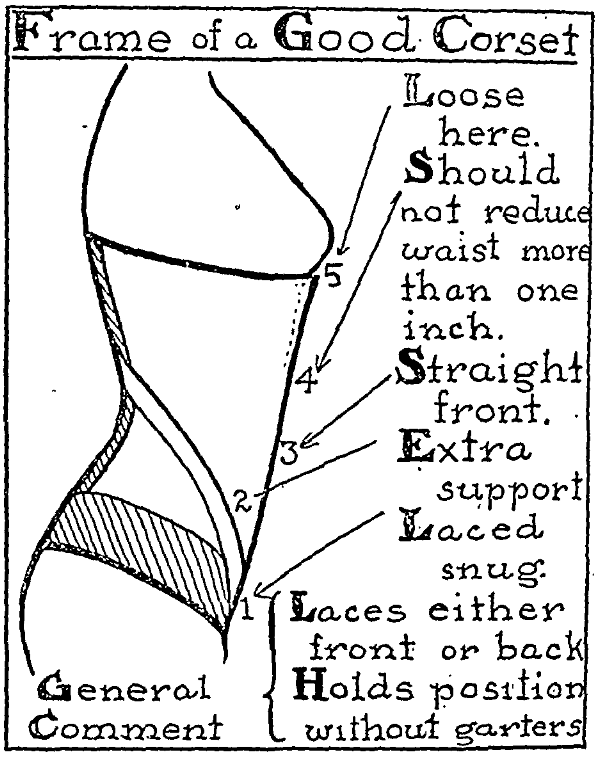
To complete the skeleton framework, a front piece less rigid than the back, but straight, should run up as high as the bust. The other main points are sufficiently explained by the diagrams.

LACING

A separate short lace string should be inserted at the hip zone and this part firmly laced first when adjusting the corset. The upper part should be more loosely laced by one or two strings. Whether the corset should be front-laced or back-laced is not of great importance. Each method has its advantages and disadvantages. The choice should be left to the corset-maker, as the situation of the lacing involves problems in the mechanical construction of the corset. The back lacing allows of the simplest construction.

The good corset is shown in Figure 1:

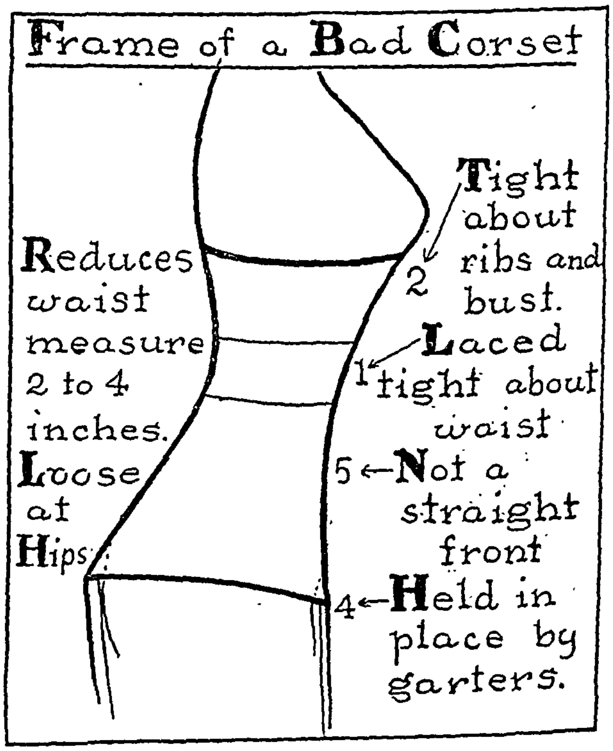
1. It is fixed by lacing about the hips and holds its place entirely independently of garters or straps.
2. It supports the lower abdomen and reduces the hips.
3. It has a straight front.



Frame of a Good Corset
Loose here.
Should not reduce waist more than one inch.
Straight front.
Extra support
Laced snug.
5
4
3
2
1
Laces either front or back
Holds position without garters
General Comment

Fig. 1.

4. It is only form-fitting or loose about the waist and bust.
5. It diminishes the waist measure not more than one inch.
6. It laces from below upward by means of two or more lace strings.



Frame of a Bad Corset
Tight about ribs and bust.
2
1
Laced tight about waist
5 ←Not a straight front
4←Held in place by garters.
Reduces waist measure 2 to 4 inches.
Loose at Hips

Fig. 2.

The bad corset is shown in Figure 2:

1. It shows the zone of greatest compression about the waist.
2. It is loose about the hips.

3. There is no provision for fixing it about the hips.
4. It is held down by garters or fixed by tight lacing in the upper portion.
5. It diminishes the waist measure from two to four inches.
6. It laces by a single lace.

In the selection of a corset the first consideration should be its conformance to the natural form. Secondly, the mechanical device for keeping the corset in place should depend on means which are not injurious. Finally, the corset should be comfortable without being sloppy. If it tends to produce the normal form it cannot do serious harm even if quite snug. Loose corsets are worse than no corsets. The worst corsets made are loose about the hips, giving them no true basis of support.

906 Butler Building.

A NEW CLAMP FOR END-TO-END INTESTINAL ANASTOMOSIS

C. E. TENNANT, M.D.
DENVER

The uncertainty of perfect approximation of the mesenteric border of the intestine has, no doubt, been the greatest objection to the suture method of end-to-end intestinal anastomosis. Because of the apprehensive post-operative period, the ingenious button device of Murphy has been largely superseded by the suture method of Connell.

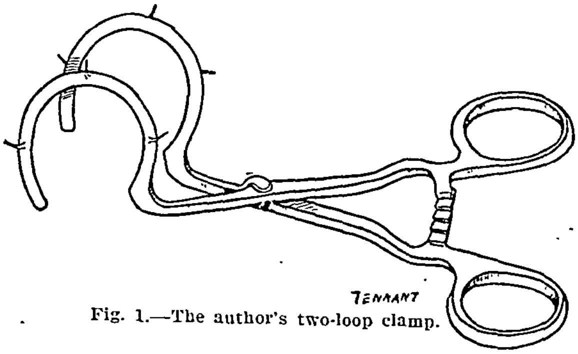


Fig. 1.—The author's two-loop clamp.

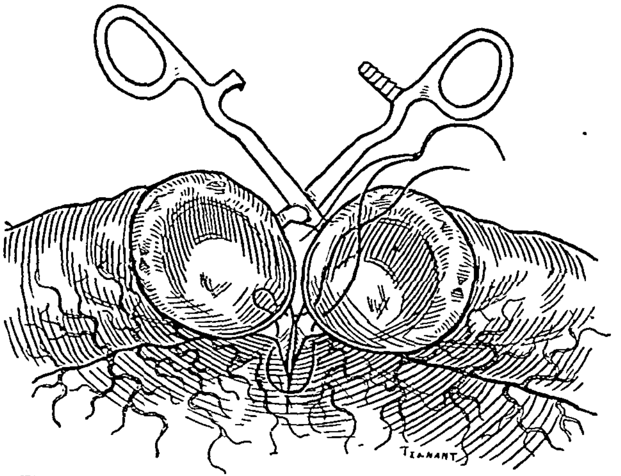

Fig. 2.—Ends of bowel grasped by loops. Mesenteric border very accessible.

The last-named method seems to have proved most satisfactory in side-to-side intestinal anastomosis. The objections to the end-to-end anastomosis are first, as stated above, the difficulty of securing perfect approximation of the mesenteric border, and second, the awkwardness of the method, necessitating as it does, considerable practice on the part of the surgeon before it can be successfully performed.

To work from the inside of such a cylindrical body as the intestine, closed with no free ends, is at first a serious mechanical difficulty. The object of the Connell method, as of all others, is of course to secure an inversion of the free ends of the intestine, thereby approximating the peritoneum. This is satisfactorily secured by the Connell method, but only after considerable practice.

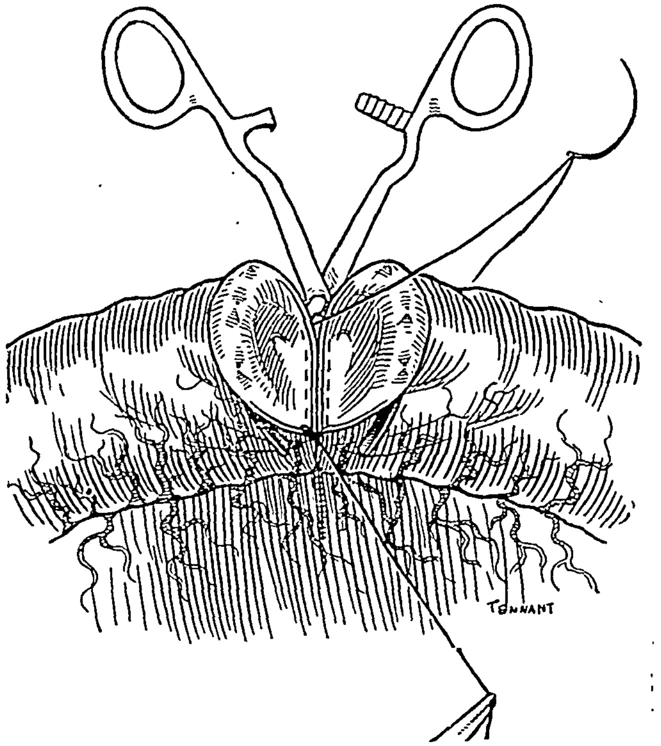

Fig. 3.—Suture half way up on each side of the intestine.

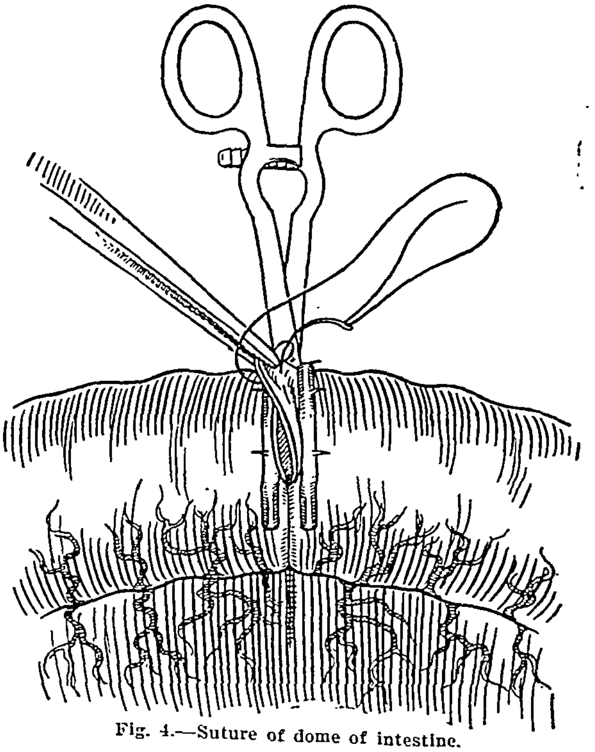

Fig. 4.—Suture of dome of intestine.

To simplify this method and, at the same time, to add to the security of the mesenteric approximation, I have devised the simple two-loop clamp here illustrated. (Fig. 1.) The clamp has a Collins lock, and is easily separated so that each end of the intestine may be engaged in its respective loop (Fig. 2), although the ends may at first be inches apart. The mere locking of the blades brings the ends of the intestine into close apposition with the mesenteric border well drawn up into the operating field. Before the clamp is completely closed, this mesenteric border is securely approximated by suture, and the continuous suture is then carried one-quarter way around each side (Fig. 3), commencing at the mesenteric border and continuing according to the Connell method.

The first tie is made at the mesenteric border with sufficient linen thread left at each end to continue around the intestine. The instrument being placed with its handles away from the operator, the suturing is continued well up on the side nearest the operator first, with the last suture entering the lumen of the intestine. The curved round needle is then transferred to the distal side of the intestine and the same Connell method is pursued as long as necessary.

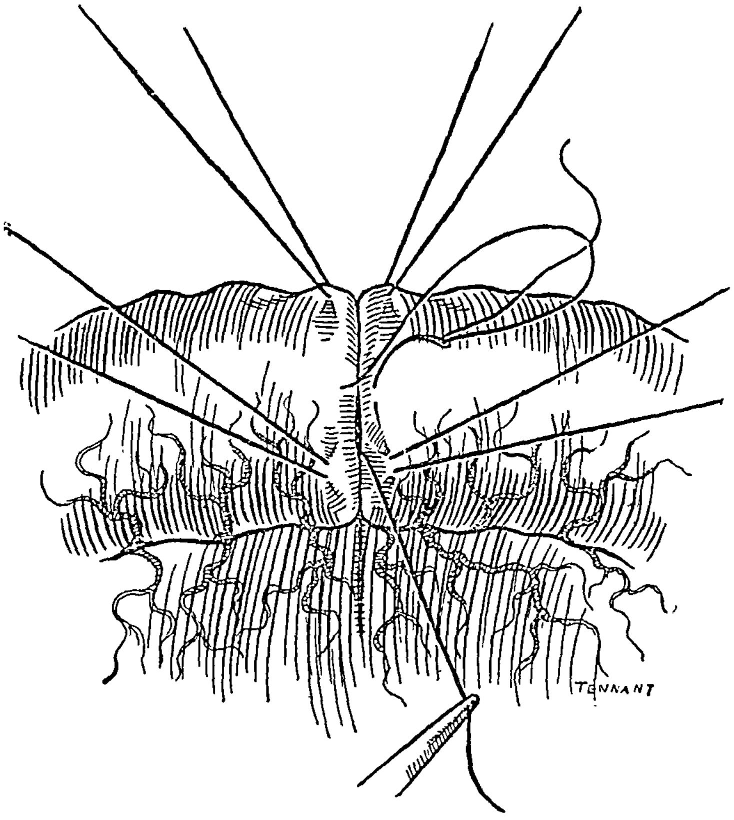

Fig. 5.—Introduction of guy stitches.

As the dome of the intestine is reached, the suture is made to emerge on the outside (Fig. 4). The clamp is then either closed and the ends of the intestine freed from the retaining pins, or the clamp is removed altogether and guy stitches introduced about 1 cm. from the free edge, as illustrated (Fig. 5). These sutures when raised tend to invert the edges of the intestine.

A Cushing parallel deep suture, including all coats of the bowel, is then commenced; this is practically the Connell suture, only right side up, and consequently very much more readily introduced.

As the two ends of the suture meet, the last is made to enter the lumen of the bowel with the final stitch. Both ends are now together, and are accordingly threaded into the eye of the needle as in the Connell plan, and the knot tied inside the bowel. A few Lembert sutures may then be applied about the sites of the guy sutures (Fig. 5), or where the ends of the intestine were impaled on the pins of the clamp.

Criles' technic of end-to-end blood-vessel anastomosis first suggested this idea, and the recent report by Pollock and Spiedel[1] deserves mention in this connection.

612 Empire Building.

A CASE OF MENINGOCOCCUS SEPTICEMIA WITH DEMONSTRATION OF THE MENINGOCOCCUS IN THE BLOOD-SMEAR

A. WADSWORTH SKILTON, M.D.
Assistant Resident Physician, Mercy Hospital
BALTIMORE

Simon[2] reported a case of meningococcus septicemia in which the meningococcus was demonstrated in the blood-smear. Since then he has found the same conditions in a second case and he has told me that two or three other men have reported similar findings to him. So far as I have been able to ascertain, these are the only cases which have been observed up to the present time, and hence it may not be out of place to report briefly the following instance in which the same findings were observed.

Patient.—A boy aged 12, was in good health until February 24, when he complained of pain over the mastoid region on both sides with some swelling and tenderness.

General Examination.—The patient was first seen on February 27 by Dr. Beck. His pulse was 100; temperature 104 F. There was neither headache nor vomiting, but slight ptosis of the left eyelid and some rigidity of the muscles of the neck and the extremities were present. On lumbar puncture, 25 c.c. of turbid fluid escaped under pressure. Smears made from the centrifugalized spinal fluid showed the menigococcus in small numbers both free and enclosed in polynuclear neutrophilic leukocytes which constituted the cytological picture.

Blood Examination.—A blood specimen gave the total leukocyte count as 7,500, 85 per cent. of which were polynuclear neutrophilic leukocytes, 4 per cent. small mononuclear leukocytes, 11 per cent. large mononuclear leukocytes, while eosinophilic and mast cells were absent. Fully 1 per cent. of the leukocytes contained diplococci, the majority only one pair, but a few contained two pairs; the organisms occurred both in the mononuclear and polynuclear cells. Extracellular organisms were not seen, although they were present in Simon's case. The number of organisms calculated per cubic centimeter in this instance was 7,500. Simon calculated 7,500,000 per cubic centimeter in his case, one neutrophilic cell alone containing over 50 pairs of diplococci.

Many of the neutrophilic cells contained vacuoles which perhaps represent empty digestive vacuoles.

CONCLUSIONS

It is possible that the occurrence of the meningococcus in the leukocytes is much more common than is generally supposed, but owing to the relatively small number of cocci in the blood and the difficulty of finding them, they have no doubt been overlooked. The positive findings in the few cases which have been carefully examined indicate, however, that in doubtful cases careful search in this direction should not be neglected.

Character.—Men build on the rocks, not on the treetops. So do nations. America owes more to the cabin than to the palace; to the man with a calloused palm than to the man with a diamond stickpin.—*United Presbyterian.*

VENOUS ANASTOMOSIS FOR CURE OF VARICOSE VEINS: VENOVENOSTOMY *

H. EDWARD CASTLE, M.D.
SAN FRANCISCO

In this paper is described briefly the technic of an operation devised by H. A. L. Ryfkogel and myself in these laboratories, and then practiced in the San Francisco Polyclinic and Post-Graduate School.

After working one year in the laboratory on the subject of vascular surgery, with comparatively uniform results, we felt that our technic was worthy of being put into practice in the clinic. Accordingly we performed Delbet's operation on several patients.

As Delbet's operation carries with it a certain amount of danger, by the possibility of thrombus formation in the femoral vein, we concluded to make an end-to-end anastomosis of a branch of the superficial femoral vein with the internal saphenous vein. By so doing, we obviate the danger from a thrombus, for if by error in technic one forms, it will be remote from the femoral vein.

The object of this operation is to reestablish a normal flow of blood in the internal saphenous vein, and in its tributaries. This is accomplished by changing the current of blood from the upper end of the saphenous vein into the superficial femoral vein. Thus the valves of the femoral vein are utilized to support the heavy column of blood which in the normal subject is supported by the valves of the saphenous. The lower part of the saphenous is relieved of all backward pressure from the inflow of blood into it from the superficial external pudic, superficial epigastric, superficial circumflex iliac, and other smaller tributaries. When this vast pressure is released the valves of the saphenous are often competent to sustain the remaining saphenous blood column.

The branch of the femoral vein that we are wont to make use of may be absent. If this should occur one has recourse to three other operations, viz., Delbet's, Trendelenburg's, or Ferguson's.

Delbet's operation, as is well known, consists of a terminal implantation of the proximal end of the distal fragment of the internal saphenous vein into the side of the superficial femoral vein. The operation is not difficult of execution for one skilled in vascular surgery, and is worthy of due consideration. Its chief fault lies in the possibility of a thrombus forming and occluding the lumen of the femoral vein.

Trendelenburg advises ligature of the saphenous in the upper part of the thigh.

Ferguson removes a section of the saphenous near its upper end and, after making a circular skin flap, removes the varicosed veins from the lower part of the thigh and those from the inner aspect of the leg.

The favorable results of venovenostomy depend almost entirely on asepsis and freedom from injury to the veins by mechanical, chemical, and thermal means. There is no danger of leakage in the suture line as the method employed is competent to obviate its occurrence.

The science of surgery is deeply indebted to Alexis Carrel, whose ingenious mind gave it this very efficient and simple technic, which is entirely adequate for any anastomosis of blood-vessels, whether it be arteries or veins, irrespective of size. At the same time, this technic is so uncomplicated and easy of execution that it can be utilized by any surgeon. The only special materials needed are China bead silk, No. 16 cambric needles, and weak clamps (tapes may be used in place of the clamps).

PREPARATION OF SUTURES

The manner in which the suture material is prepared is of vital import. We have tried many methods with much dissatisfaction, but now employ the one here described with entire safety and little inconvenience.

The needles are threaded with China bead silk as it comes from the market, or it may be split. Then the threaded sutures are sewed into a piece of gauze bandage. They are rolled so as to avoid bending the fine needles, and put into a wide-mouthed ounce bottle. The bottle is filled with warm petrolatum, and put into the autoclave for sterilization. When removed from the autoclave, the bottle is sealed with wax and so kept until needed. At the time of operation, the bottle is washed with pure liquor cresolis compositus. After the bottle has been washed free from all the antiseptic it is opened by sterile hands which are covered by gloves.

PREPARATION OF PATIENT

The evening prior to the operation the patient is given 2 ounces of castor oil, the leg is washed with soap and water from hip to knee, and covered with sterile gauze. One half hour before operation the patient is given $^1/_6$ grain of morphin sulphate and $^1/_{100}$ grain of atropin sulphate hypodermatically.

When the patient is on the operating table three coats of iodin are applied to the field of operation. Along the proposed line of the incision the iodin is removed with alcohol immediately preceding the beginning of the operation. Nitrous oxid and oxygen, or ether, is administered in the smallest amount that is sufficient to keep the patient quiet.

OPERATION

An incision 3 inches in length is made along the inner edge of the sartorius muscle and over the lower part of Scarpa's triangle. The linen is sewed to the skin at the edge of the wound with closely applied interrupted sutures, so as to avoid as nearly as possible any contamination from the skin, either chemical or bacterial. The wound is retracted inwardly and the internal saphenous vein immediately found lying buried in fat external to the fascia lata. It is freed from fat and adventitia. The vein is then ligated in the upper angle of the wound. Two inches distal to the ligature it is clamped with a Langenbeck serrefine, which clamp must have a soft spring, and the vein is severed with a sharp knife. We never employ scissors for cutting the vessels, on account of the crushing effect. The distal part is washed clear of all blood remaining in its lumen with Locke's solution, or normal salt solution. The vein is then heavily coated with petrolatum, and it is ready for anastomosing. The next step is to seek the branch of the femoral that is to be anastomosed to the saphenous.

By opening the fascia lata over Scarpa's triangle the internal cutaneous and long saphenous nerves are seen crossing the vessels from without inward. The crural branch of the genitocrural nerve lies in the sheath of the vessels, slightly external and anterior to the artery. The artery lies anterior to the vein, leaving only a slight margin of the latter to be seen on inspection. The vein is separated from the artery and a large branch is sought. When found it is ligated about 2 inches from the femoral vein. Then a Langenbeck serrefine is placed on the branch near the femoral vein. The branch is then cut about 2 inches from the femoral and treated as was the saphenous.

---

* From the Laboratories of Experimental Research, State University of California.

The distal end of the saphenous is then joined to the proximal end of the branch of the femoral in the following manner:

Three guy sutures are placed so as to unite the two veins, and so as to divide their circumference into three equal parts. When made taut, the circumference of the veins forms a triangle which has a guy suture at each angle. For descriptive purposes these guy sutures will be labelled I, J, and K. If traction is made on I and J by an assistant, the surface I J of the triangle will be brought anterior and made accessible for the introduction of the continuous suture which is to be used to unite the vessels permanently. If traction is at the same time made on K by a weight (we employ an artery clamp for this purpose) the sides of the vessels are drawn away from the surface that is being sutured, and thereby are prevented from becoming injured by the passing needle. These guy sutures have another function, viz., they elevate a slight collar at the margin of the vessels which is equal in depth to the distance they are placed from the free edge of the veins. This facilitates the introduction of the stitches of the permanent suture which is to be placed.

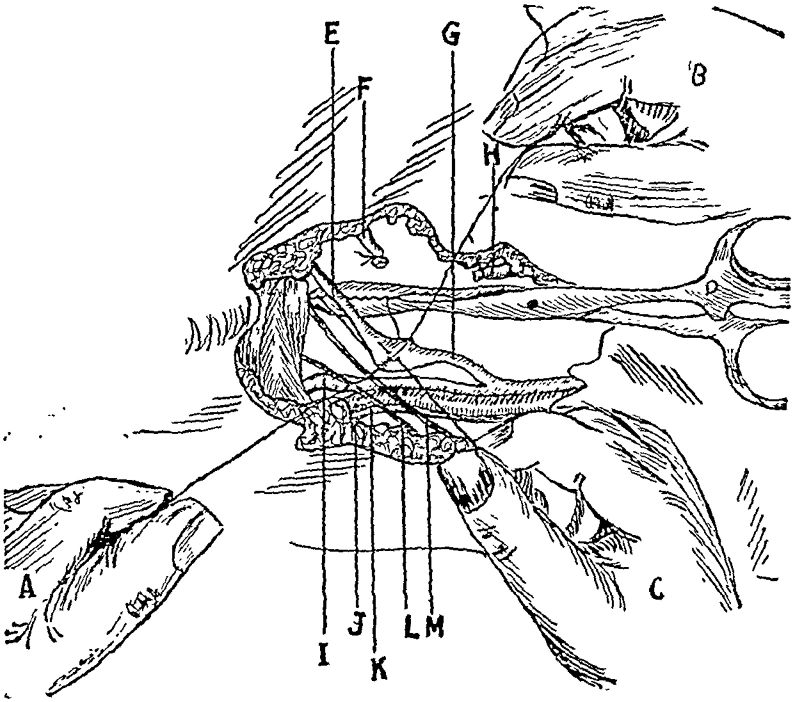

Diagram to illustrate the procedure of venous anastomosis for varicose veins: A and B, hands of assistant making traction on anterior guy sutures; C, hand of surgeon passing continuous suture; D, weight on posterior guy suture; E, distal end of saphenous vein; F, distal end of branch of femoral vein; G, proximal end of branch of femoral; H, proximal end of saphenous; I, femoral vein; J, femoral artery; K, crural branch of genitocrural nerve; L, internal cutaneous nerve; M, long saphenous nerve.

We now begin a continuous suture at guy suture I, including in the grasp of the stitch only the fine collar raised by the traction on the guy sutures, and placing the stitches as closely together as possible. This suture is responsible for the prevention of all leakage, therefore, it must be accurately applied. It passes through the entire walls of the vessels, and brings intima into contact with intima. It is important to avoid any adventitia being drawn into the lumen of the vessels, as blood is prone to clot when in contact with foreign tissues. This continuous suture is carried completely around the vessels and tied to its free end when the latter is reached. The assistant changes the weight and his hands to the proper guy sutures when the continuous suture reaches the consecutive angles of the triangle.

The anastomosis is thus completed and when the serrefines are removed the veins fill at once with blood. There is no bleeding if the suturing has been executed properly, but if there be a bleeding point an interrupted suture will suffice to stop it. The deep tissues are closely and carefully adjusted around the area of the anastomosis to avoid as much as possible any dead space, and sutured with No. 0 iodized catgut sutures. The sartorius is allowed to fall back into place, and the integument is closed with the fine artery needles.[1]

The patient is put into bed, and his leg kept elevated for two days; after this length of time he is permitted his freedom.

1820 Sutter Street.

RESUSCITATION BY CARDIAC MASSAGE

CHARLES H. FRAZIER, M.D.
PHILADELPHIA

Cardiac massage was first suggested by Schliff in 1874, but not until 1898 was it applied to man. Since then, and with each succeeding year, an increasing number of cases have been recorded with a fair measure of success.

This extraordinary power of the heart to resume its function after death under certain physical conditions is well known to the laboratory worker. I think that it was Kuliabko who first demonstrated that the isolated heart could be made to contract by injecting Locke's solution into it under pressure, and that too after the heart had remained in a frozen salt solution for a period of twenty-four hours. The essential factors for the resumption of the cardiac mechanism are the presence of a certain amount of fluid in the ventricles and the necessary pressure in the coronary arteries. In the laboratory, these factors may be provided by injecting into the carotid artery toward the heart normal saline solution charged with epinephrin. Spina of Prague obtained similar results by injecting 200 c.c. of saline solution into the veins of a dog; this forced the blood along before it and when the semilunar valves were reached the stream closed them and the blood was driven into the coronary arteries.

While these methods have proved successful in the lower animal they have not, so far as I know, been applied with equal success to the human subject. When, for one reason or another, the action of the heart has been arrested there remains but one practical method of resuscitation, namely cardiac massage. Although the majority of instances in which this procedure has been resorted to have been those of chloroform syncope, it has been recommended when the syncope is the result of drowning or asphyxia, and when due to the suspension of function from simple exhaustion or injury.

The following case recently came under my observation:

Patient.—R. T., male, aged 55, reg. No. 2840 (P. E. H.) was admitted to the hospital Oct. 3, 1910. The diagnosis was hydrocele. There was nothing of significance in his family or personal history. He was a moderate user of alcohol. There was no lesion of the lungs and the heart sounds were clear, rhythmical and of good quality.

Operation.—The patient was prepared for operation for the radical cure of hydrocele. The anesthetic at the beginning was ether; difficulty was experienced in its administration, however, and as the patient had taken an unusual amount without the desired result, chloroform was substituted apparently with satisfactory results.

---

[1] Wound Closure with Minimum Scar, The Journal A. M. A., April 24, 1909, p. 1333.

Collapse and Treatment.—The operation had just begun, the incision was made, when it was observed that the patient had become intensely cyanosed. In a moment he was pulseless and soon afterward respiration ceased. The head of the table was rapidly lowered and artificial respiration at once resorted to. Realizing the otherwise hopeless situation, the abdomen was rapidly opened and with one hand on the chest wall and the other against the diaphragm I massaged the heart at the rate of from 15 to 20 movements to the minute. The actual time was not recorded in the excitement of the moment, but in approximately 2 minutes feeble but irregular fibrillary contractions were felt. Gradually the impulses became more forcible and more regular, and after an interval of 8 minutes, during which time massage was continued, resuscitation seemed assured. At this time the pulse-rate registered 130.

Result.—The abdominal wound was closed, the operation on the hydrocele completed and the patient returned to the ward. The subsequent history was uneventful.

In a series of forty-six cases, reports of which are collected by Cockovic,[1] in seventeen the results were classified as positive and in twenty-nine as negative. Of the former, in only nine was the effect permanent; in the other patients survived for from five to twenty-seven hours. Thus there was only 20 per cent. of successes.

Perhaps the most important practical consideration is the method of procedure. Shall the heart be massaged directly through a thoracoplastic opening, by the transdiaphragmatic or by the subdiaphragmatic route? Dismissing any theoretical considerations, we find the best results are obtained by the subdiaphragmatic route. In sixteen instances of the latter there were ten positive results, in twenty-four of the thoracic route only seven; and in the six cases by transdiaphragmatic route there were no resuscitations.

The following table[2] shows the relative value of the various methods:

	Successful.	Partially Successful.	Failures.	Total.
Direct	2	8	18	28
Transdiaphragmatic	0	1	2	3
Subdiaphragmatic	8	5	6	19
Total	10	14	26	50

Because of its greater simplicity and higher percentage of recoveries the subdiaphragmatic route should be adopted as the conventional procedure, except perhaps in children in whom the elasticity of the chest wall enables one to make adequate pressure on the heart without opening either chest or abdomen. How long one is justified in waiting before resorting to massage may be judged from the fact that there have been no recoveries when the syncope has been of more than ten minutes' duration; and the largest measure of success was obtained when the interval did not exceed five minutes. The sooner the massage is begun, therefore, the brighter the prospects. As the proper oxygenation of the blood is indispensable to resuscitation, artificial respiration should at the same time be practiced, or direct insufflation by the Auer-Meltzer method.

In a case reported by Rehn,[3] failing to resuscitate the patient by subdiaphragmatic massage and Sylvester's method of artificial respiration, he opened the diaphragm, practiced direct massage, and at the same time established positive pressure with the Brauer apparatus. The result was almost instantaneous on both heart and respiration. In two hours the respirations failed again and further attempts at resuscitation were ineffectual. The secondary collapse was attributed by Rehn to a pneumothorax, which developed when the pleura was torn in opening the diaphragm.

NOMA (CANCRUM ORIS) IN AN ADULT, WITH REPORT OF A CASE

HOWARD D. KING, M.D.
NEW ORLEANS

Noma in the aged is of such unusual infrequency, compared with its occurrence in children, that I am induced to record a case which came under my observation in the summer of 1910. Considering the rarity of the condition as well as the scarcity of the literature dealing with the disease, especially as relates to its presence in the aged, I believe that I am justified in offering a brief account of the nature of noma.

Noma is a rapidly progressive and probably specific infectious process of a gangrenous type, causing extensive tissue destruction and usually having its origin on the mucous membrane of the vulva, gum or cheeks, and sometimes, though seldom, the ear or anus. Noma affecting the region of the cheeks or gums is known as cancrum oris; involvement of the vulva is termed noma pudendi.

Children between the ages of 3 and 8 years are most frequently attacked; the disease occurs more frequently in girls than in boys. This sexual predisposition continues throughout life and is not due to any peculiar susceptibility, but to the fact that the female genitalia offer a more suitable field for infection. Text-books on pediatrics are almost unanimous in declaring the condition to be one essentially of childhood and that the disease is not seen in nurslings or adults. That this impression is somewhat erroneous will be seen from the case reports below.

Between the years 1848 and 1903, an interval of fifty-five years, several cases in the aged have been recorded in medical literature. Tourdes[1] 1848, reported nine authors who had seen noma in persons between 15 and 72 years of age; von Bruns[2] 1859, from 413 cases collected by him, found only eleven in persons whose ages ranged between 15 and 70; Strueh[3] 1872, reports a case of his own in a patient aged 30, and calls attention to a case observed by Vogel in a youth of 18; Hildebrand[4] 1873, collected a series of cases numbering twenty-two in persons over 15 years of age; Brydon[5] 1882, one case; Herman[6] 1883, one case; Murillo[7] 1886, one case; Herff[8] 1890, one case; Masterman[9] 1891, two cases; Koster[10] 1892, one case; Stephenson[11] 1892, seven cases; Ziegler[12] 1892, one case; Le Count[13] 1898, one case; Mangubi[14] 1898, one case; Zusch[15] 1901, one case; and Reale[16] 1903, one case.

Poorly nourished, cachectic subjects and those living under vitiated environments are said to be the types most frequently affected. That filth, squalor and tenement life are not alone responsible for the disease

has been conclusively demonstrated in more than one instance, especially in the epidemic of noma which occurred in an orphanage at Albany, N. Y., where good practical sanitary, hygienic and dietetic conditions prevailed. It also occurs very frequently as a complication of the exanthemata, notably measles.

In the above-mentioned cases of noma the underlying conditions have been most varied. Thus, we see the disease, according to the case reports, following erysipelas, typhoid fever, amebic dysentery, pleuritis and nephritis. Stephenson[11] regards renal disease as an important factor in the causation of cancrum oris in the aged.

The exact status of the disease as to etiology has not been definitely established and is further rendered confusing by the multiplicity of the terms used in the description of the malady. Noma, at all events, is a rare condition, but its assumed rarity was very probably due to the difficulty experienced in recognizing an exact causative organism. At the present time, even, it is by no means certain that the organisms described by investigators of the past have anything to do with the disease. The frequent use of the term "noma" synonymously with "gangrenous stomatitis" is to be regretted, as the latter term is purely a generic one and of no precise significance, nor does it furnish us with any adequate idea of the existing pathologic condition. The following terms have been used and are to-day employed to describe noma: gangrenous stomatitis, gangrena oris, gangrenopsis, stomato-necrosis, necrosis infantilis, buccal anthrax, water canker, cancer aquaticus, and sloughing phagedena. *Wasserkrebs,* a term originally coined by A. Richter in 1828, in his initial treatise on noma, is the name given the disease by the Germans. The French use the phrase *gangrène de la bouche.* The foregoing terms are a source of confusion and of no importance save from a symptomatic standpoint.

Reverting to the etiology of the disease, it was once believed to be the manifestation of some neural disturbance, owing to the almost invariable occurrence of the disease in a certain part of the cheek. Whether the disease is some form of mycotic necrosis, as first claimed by Froriep[17] or of bacterial origin, is still an open question. Lingard[18] found in the tissues long, thread-like growths, the individual threads being composed of small bacilli. He reported also finding a bacillus similar to the above in a calf suffering from what was apparently cancrum oris. Ranke[19] found in noma tissues certain cocci, the specific nature of which have never been recognized. As a result of his findings, Ranke concluded that different forms of gangrene resulting from noma unquestionably occur in children who have a tendency to disease of this character; i. e., without infection from contact.

The endemicity of the malady in public institutions coupled with the seeming choice of the disease for localization on the mucous membrane of the different openings of the body suggest that the causation may be looked for in the invasion from without of microorganisms. Schimmelbusch,[20] as a result of his bacteriologic study of one case, found bacilli often in shortened pairs and sometimes in long filaments.

An extremely good digest of the subject of noma is given by Blumer and McFarlane,[21] who have reported a series of sixteen cases occurring in epidemic form which they accepted as undoubted noma. As a result of their investigations, they concluded that the disease began as a simple infection and terminated in a mixed infection, and that the mixed infection was not always due to the same organism, but was usually due to a long organism of a leptothrix type. In a most elaborate and highly interesting treatise on noma by Weaver and Tunnicliffe[22] is incorporated the results of the bacteriologic researches concerning noma as undertaken by Grawitz, Bartels, Guizetti, Babes, Zambilovici, Foote, Nikolaysen, Schmidt, Petruschky, Freymuth, Saft, Krahn, Seiffert, Perthes, Braun, Matzenauer, Elder, Ranke, Rosenberger, Brunning, Rona, Buday, Pollard, Herrman, Passini and Leiner, Walsh, Sailer, Strueh, Schimmelbusch, Longo, Hofmann, and Kuster. In the majority of the cases of the above observers the superficial parts of the slough showed mixed cultures; in the deeper parts, the sections often showed almost a pure growth. The organisms most frequently found were slim, thread-like bacteria, decolorizing rather easily by Gram and not growing on ordinary media.

REPORT OF CASE

History.—June 4, 1910, I first saw Mrs. E. M. F., a housewife, aged 59, whose family history was of no material value. The patient was the mother of eight children; had one miscarriage; menstruated at 14; climacteric reached at the age of 43 without any untoward results. For the last eighteen or twenty years previously the patient had had very poor health, being almost constantly ill with gastric and intestinal disturbances. As the patient tersely stated it: "All my life I have been a sufferer from loose bowels and heartburn." Within the past five years the patient has been afflicted with articular rheumatism. Queries as to previous treatment revealed the fact that during the previous five months the patient, at seven different intervals, had taken large amounts of calomel in broken doses. She declared that her former physician advised her when feeling unwell to take a dose of calomel. A daughter of the patient aptly termed her mother a "calomel fiend."

Examination.—Patient looked at least ten years older than she really was. She was wrinkled and emaciated, and bore all the earmarks of a woman who had had a strenuous struggle with life. Evidences of insufficient nourishment and hard work were most striking; personal hygiene very bad; living environments wretched. On going over the patient very thoroughly I found that I had to deal with a chronic interstitial nephritic condition, complicated with endocarditis.

Treatment and Course of Disease.—As it was apparent that the patient's span of life was drawing to a close, only simple palliative measures were resorted to. Under this mode of treatment the patient maintained her balance for a fortnight, when early on the morning of the fifteenth day of her illness my attention was directed to a slight swelling on the left side of the face. Examination of the mouth revealed an ulcerated patch on the mucous membrane of the gum covering the outer aspect of the mandible. The teeth were carious and disgustingly dirty; the lower teeth were artificial; there was a limited amount of exudation. The odor was most fetid. I prescribed an oral antiseptic and promised to call again the same evening.

On my second visit the swelling had increased and had extended more to the middle line. There had been a slight hemorrhage at this time and the exudation had increased. Within the short space of seven hours the ulcerative process had become a dark and dusky red, which was soon followed by a circumscribed area of dead exudate. There was also a slight sloughing which the patient was trying, in vain, to expectorate. It was at this juncture that Dr. Stephen W. Stafford kindly consented to see the patient with me. As a result of his examination, he concurred in my diagnosis and immediately pronounced the condition cancrum oris. The disease was now spreading rapidly and there was a well-marked line of sloughing tissues following the imprint of a set of false (lower) teeth. The frenum of the lower lip soon became involved and it seemed that that portion of the mouth between the outer mucous membrane of the alveolar process and the inner side of the cheek was literally rotting away. The odor at this time had become so bad that it appeared to invade the whole household. It was most disgusting and the deodorants employed proved of little value.

[21] Blumer and McFarlane: Am. Jour. Med. Sc., xxii, 527.

[22] Weaver and Tunnicliffe: Jour. Infect. Dis., 1907, iv, 8.

On the morning of the third day the frenum of the lower lip began to split from within outward and the whole of the inner aspect of the mucous membrane of the left cheek was one black, greenish and garnet mass, attended with a slight hemorrhage. The tongue was swollen beyond its natural size and deglutition was very difficult. Speech was painful and required great effort.

Later the same day the tissue destruction had progressed to such an extent that the inner angle of the cheek began to break down. The patient's condition at this time was most serious and death was but a question of a few hours. There was profound prostration, feeble pulse and retention of urine. The patient's condition rapidly grew worse, she soon went into a typhoid state and died that night at 11 o'clock. Only twice during her illnes did the temperature go beyond 100 F.

June 21, tissue scrapings and oral secretions were submitted for bacteriologic study to Dr. William H. Seeman, who made the following report:

Slide 1.—Leishman (Romanowsky) staining. *Spirochæta dentium* present in considerable numbers. Great quantities of pus cocci. Organism of a leptothrix type plainly discernible. Fusiform bacilli present, but not to any marked extent.

Slide 2.—Weak carbol-fuchsin staining. Innumerable spirochetes easily demonstrable. Bacilli also present which seem to be the early stage of some form of spirillum. In no way does the latter resemble Vincent's spirilla.

Anaerobic culture yielded practically negative results. Pus cocci and non-pathogenic bacilli found. The culture failed to show any thread-like organisms.

It was fortunate that during the above examination Dr. Seeman had at the same time submitted to him secretions from a case of Vincent's angina and he made comparative examinations between the specimens of the two cases. As a result of this comparative bacteriologic study, Dr. Seeman was able to determine very distinctly the morphologic and cultural differences between the causal organism of Vincent's angina and the organism which probably causes noma. The essential difficulty of recognizing a certain and definite causative organism is usually obscured by the great number of bacilli of uncertain character which are always found in nomatous tissue. Moreover, it must be noted that in the mouth of the normally healthy person bacteria are always present in large numbers and the following have been found: *Spirochœta dentium, Spirillum sputigenum, Bacillus buccalis maximus, Iodococcus vaginatus,*[23] *Leptothrix buccalis innominata* and the *Leptothrix buccalis maxima.* In all likelihood, they are non-pathogenic. The existence of dental caries always proves a most favorable nidus for microorganisms. Aside from this, it is interesting to note that the following pathogenic microorganisms may also be present in the mouth under apparently normal conditions: the *Diplococcus pneumoniæ, Diplococcus lanceolatus, Micrococcus septicæmia sputi, Streptococcus pyogenes, Micrococcus tetragenus, Bacillus crassus sputigenes,* and the *Bacillus coli communis.*

From a consideration of the case just recorded it is possible to obtain a clinical picture of the disease. The diagnosis does not present difficulties when the disease is well established. However, noma, when affecting the genitalia, might be mistaken for ulcerating granuloma of the pudenda. The symptoms are similar in some respects to those encountered in infectious submaxillary angina (Ludwig's). In fact, in many cases it is impossible on clinical grounds alone to distinguish angina from noma. Ludwig's angina differs from noma in that it displays more of a tendency to destroy loose tissues and avoid the denser ones. It often happens that Ludwig's angina terminates in gangrene.

The symptoms produced by noma in the aged do not differ materially from those seen in childhood. It can be readily seen that the predisposing factor in the foregoing case was a frail human economy whose vital powers were lowered by chronic renal and cardiac disease, to which were added insufficient nourishment and vitiated environments. It may be asked if the heavy calomel medication just prior to the last illness may not have played its part in aiding the condition. While it is possible that there may have been a condition bordering on mercurialism, it must be borne in mind, says Reisman,[24] that mercury as a causative factor in this condition has been absolutely disproved, quoting Coates[25] in support of this view. Dr. Benjamin Rush[26] cites an instance in which a colleague of his, Dr. Stewart, was in the habit of giving 20 grains of calomel three or four times a day and continuing this as routine treatment for five or six days without any ill effects. It is to this same Dr. Stewart that modern syphilographers owe the idea of mercury medication by inunction, as he was the first to compel patients to wear socks containing mercurial ointment in the treatment of luetic conditions. Dr. Stafford, who saw the case in consultation, also rejects the idea of calomel medication having anything to do with the production of the disease.

The condition of the patient at all times precluded the possibility of ever doing anything except to institute palliative measures. The drastic treatment so necessary for a cure in these cases was entirely out of the question.

CONCLUSIONS

1. Noma does exist in the aged, but its occurrence is remarkably rare.

2. Noma in the aged does not differ materially from the disease as seen in childhood. The supposed predilection of this malady for the female sex is due alone to the fact that the female genitalia offer a more suitable field for infection.

3. No certain and definite organism has been definitely established as the causative factor; the indictment of the long, thread-like bacillus, so frequently regarded as the cause of the disease, is on purely conjectural grounds. While in the realms of the hypothetic metabolic retrogression brought about through previous illness, vitiated environment and bad hygienic conditions may effect a change in the pathogenicity of the previously harmless microorganisms of the mouth to such an extent as to cause an overwhelming of the tissues of the cheeks and jaws, and thus produce gangrene and a condition of general sepsis.

4. Infectious submaxillary angina may be the forerunner of noma, and once the gangrene arises it would be difficult, indeed, to say whether the condition was due to Ludwig's angina or noma. This, too, despite bacteriologic observations, as it is more than probable that the two conditions could be coexistent. It is highly probable that noma is a process caused by more than one type of organism.

THE CHEMISTRY OF NEPHRITIS *

HOWARD T. KARSNER, M.D.
Demonstrator of Pathology, University of Pennsylvania
PHILADELPHIA

The purpose of this paper is to present, as concisely as is consistent with clearness, the chief points in the chemical changes which occur in an organism suffering with nephritis. The aim is to confine the remarks to those non-suppurative forms of nephritis, which are termed Bright's disease, rather than the various suppurative or other focal lesions due to localization of bacteria. If, throughout the paper, many of the statements seem dogmatic, the necessity for brevity must be held accountable. Lengthy argument would only seem to render less clear a subject which, at best, is but in its developmental stages. The point of view presented is taken to represent that which is most modern and most widely accepted.

It is proposed to take up the subject in this sequence:

I. Review of normal metabolism of proteins, fats, carbohydrates and salts, in reference to excretion of intermediate and end-products by the kidneys.

II. Metabolism, excretion and retention in (a) acute nephritis, (b), chronic nephritis of interstitial and parenchymatous varieties.

III. Metabolism, excretion and retention in nephritis with uremia, with a consideration of the theory of internal secretion.

IV. Metabolism, excretion and retention in nephritis with edema.

V. The relation of chemistry to vascular hypertension and cardiac hypertrophy.

I. NORMAL METABOLISM OF PROTEINS, FATS, CARBOHYDRATES AND SALTS

The foods ingested are in the form of proteins, fats, carbohydrates, inorganic salts and water. The end-products of fats and carbohydrates are carbon dioxid and water, the former excreted chiefly through the lungs, the latter through lungs, skin, intestine and kidney. If for some reason the metabolism of the carbohydrates is incomplete, the intermediate products can be excreted by the kidney for a long time with little disturbance in this organ, as may be seen in diabetes. Late in the course of this disease one often sees a large, pallid kidney which, however, may possibly be caused by other factors than the mere excretion of glucose, beta-oxybutyric and diacetic acids. In the case of fats the intermediate products, and even the emulsified fat itself, as in cases of lipemia and lipuria, may be excreted without apparent influence on the kidney. Inorganic salts and water apparently pass through the organ with no difficulty in health. The end-products of protein metabolism, urea, carbon dioxid plus water, also are eliminated with no difficulty, but in those diseases in which the necessity for the elimination of intermediate products appears, the universal incidence of some form of chronic nephritis would seem to indicate that these bodies, the purins, ammonia, carbamic acid and uric acid, have a distinct irritative effect on the kidney.

It is believed to-day that urine depends for its water and inorganic salts on the activity of the glomerules, and for its organic constituents on the activity of the epithelial cells of the tubules; but the nature of the changes in the materials passing through the epithelium has been incompletely studied and is vaguely understood. It is known, however, that the epithelium has synthetic power, as is seen in the building up of hippuric acid from benzoic acid, the latter a metabolite of intestinal putrefaction. Anabolic activity is evidenced in the formation of creatinin from creatin. Aside from this meager information the chemical changes in the kidney itself form a chapter for investigation that can only be opened with newer and more exact methods of experimentation and observation.

II. METABOLISM, EXCRETION AND RETENTION IN ACUTE NEPHRITIS AND CHRONIC INTERSTITIAL AND CHRONIC PARENCHYMATOUS NEPHRITIS

In nephritis the elimination of the end products of metabolism has been studied extensively with the idea of learning to what degree the disease may cause retention of final or intermediate products and what influence the disease may have on metabolism in general, either directly or through the retention of injurious metabolites.

For the purposes of this paper it is sufficient to classify nephritis as acute, chronic interstitial and chronic parenchymatous.

In the course of acute nephritis the retention of the products of protein metabolism, as shown by the determination of the total quantity of nitrogen eliminated, in relation to the total nitrogen ingested, usually is very considerable. This is especially evident in the earlier stages of the disease when the total excretion of urine is almost *nil.* Later in the disease, however, as the amount of urine increases, the output of nitrogen increases and may be relatively excessive for several days, apparently in the attempt to get rid of that stored up in the organism during the preceding period of depressed excretion.

A very important feature, that of sodium chlorid excretion, which will be discussed more fully in connection with edema, may be dismissed at this point with the statement that in a general way in acute nephritis it parallels that of nitrogen. Exceptional cases have been described in which the ability to excrete sodium chlorid was very much less than the ability to excrete nitrogen, and, indeed, any other urinary constituent, even including water. Experimentally it has been found that in those forms of nephritis in which the tubules especially are affected, the nitrogen output is diminished, whereas this is not the case where the glomeruli are affected almost to the exclusion of tubular disease.

In the chronic nephritis of both interstitial and parenchymatous forms the nitrogen elimination is variable. For periods of days and even weeks there may be well-marked retention of nitrogen amounting to as much as 4 gm. a day, but this cannot persist for a great length of time and usually is followed by a period in which the elimination of the retained nitrogen becomes evident in an amount of urinary nitrogen far in excess of the intake. This relation is not peculiar to the one form of chronic nephritis rather than the other, nor does prolonged retention necessarily excite uremic attacks. Particular kinds of diet have little influence on the condition; nor does the amount of water ingested give rise to considerable differences in the nitrogen excretion. Up to the present time these striking variations in nitrogenous output cannot be definitely explained. Attempts are being made to differentiate chronic parenchymatous and interstitial nephritis by the use of phenolsulphonephthalein but the work at the present time is insufficiently controlled by autopsy findings and is not to be accepted as final.

---

* Presented before the County Medical Society of Philadelphia as part of a Symposium on Nephritis, March 8, 1911.

Before discussing the chemistry of the accidents or complications of nephritis it may be well to briefly consider the variations in the normal constituents of the urine caused by the nephritic process and to consider the elements new to the urine as a result of the disease.

It is but natural to expect that the amount of urea in the urine of nephritics is subject to the same variations as have been indicated in discussing nitrogen. Not only do the amounts of urea and nitrogen excretion parallel one another, but in addition the amount of ammonia follows the same curve. Most recent observations lead to the belief that much of the ammonia in the urine, either normal or pathologic, is the result of decomposition; but urine preserved under uniform conditions would show variations in ammonia dependent largely on the variations in the amount of urea. Uric acid and the purins show very much less variation than the urea, although occasional cases occur in which retention of uric acid occurs; in such cases, however, the retention of urea is considerably greater than that of the uric acid. Under normal conditions the amount of creatinin in the urine is quite constant. In nephritis, however, it is said to be subject to considerable variation, but the question is one that is by no means settled. The most important feature in connection with this phase of the subject is that the older theory holding creatinin retention to be the cause of uremia has been abandoned. In the same way, the question of the amount of hippuric acid in the urine is unsettled.

Turning to the inorganic salts, we find that phosphates and sulphates are retained and eliminated in amounts parallel to that of nitrogen. This is not true, however, as regards the chlorids for, although numerous cases can be found in which the chlorid output is fully equal to that of the normal patient, yet in other cases considerable deviations from the normal may occur. These deviations may be of three types: (1) a marked daily variation, even with a uniform diet; (2) a marked excess of chlorid output, in which case the patient is usually one recovering from a period of retention, such as might be seen in an acute or subacute attack of nephritis or in patients with a disappearing edema; (3) a notable retention of chlorids. In the last group some instances are those of more or less permanent disability to excrete chlorids on the part of the kidney, a condition not especially relieved by dietary restriction; whilst, on the other hand, some instances represent a temporary embarrassment of the kidney, due to relative or absolute excess of chlorids in the diet, a condition which is relieved by diminishing the dietary chlorid intake for a short period, during which time the organ often regains its normal power of chlorid excretion.

Of great importance in connection with the variations in these normal urinary constituents is the excretion of water by the kidney. The bearing that this has on the chemistry of the organ is that excesses of water excretion aid in excretion of solids, and diminution of water excretion hinders the output of solids. The question of water excretion in this connection, however, seems more that of the physiologist than of the chemist.

Of the abnormal constituents of the nephritic urine, albumin is of most importance and interest. The albumins found are especially serum-albumin, serum-globulin and nucleoprotein. In dietary excesses in the presence of a normal kidney the albumin found in the urine is that which has been ingested. In kidney disease the same phenomenon, with but slight modification, may be observed. The identity of these proteins has been proved by the precipitin test. The serum albumin is almost always found associated with globulin in the urine and various attempts have been made to attach diagnostic importance to the relation between the two. This has failed, however, except possibly in the case of amyloid kidney, in which the amount of globulin is said to exceed that of the serum-albumin. It has also been claimed that in cases of cyclic albuminuria the albumin present is largely in the form of a protein, very much like, or identical with, one of the serum-globulin fractions. Nucleoprotein is of especial significance in connection with acute nephritis and fever cases. Albumose has no direct bearing on nephritis and when present in this disease represents a hydration of the urinary albumin present as a result of the disease. Why the kidney is impervious to the serum-proteins in health and pervious to them in nephritis remains an open[19] question. Nor is it helped by the reflection that cell-proteins (e. g., hemoglobin) and protein-products (albumose) pass through the normal kidney without apparent resistance on the part of the organ.

III. METABOLISM, EXCRETION AND RETENTION IN NEPHRITIS WITH UREMIA

The accidents of nephritis, particularly uremia and edema, present much for study by chemical and physiologic methods. Uremia is certainly a toxic condition and many attempts have been made to identify the particular toxic agent responsible for it. Theory after theory has been discarded, with the result that the problem still remains unsolved. Nevertheless, certain phenomena of metabolism in the process have been worked out very concisely. Nitrogen excretion in uremia is usually low, but that it is the cause of the condition is combated by the fact that many nephritics show depressed excretion of nitrogen and are quite free from symptoms of uremia. Much more insistent claims have been made for intermediate products of protein metabolism, such as uric acid, carbamic acid and ammonia, as the etiologic agents in uremia, but more careful research has shown that even though these substances are retained they are not responsible for the condition. Inorganic salts have been held responsible for uremia and the discovery that the urine of uremics is of higher molecular concentration than normal led to the inference that the increase was due to salt concentration.

The fact was soon discovered, however, that increased molecular concentration appears in other diseases than nephritis and without uremia, and further, that the increase cannot be due to inorganic salts, because the urinary electrical conductivity remains the same as for normal urine. Alterations in the supposed internal secretions have been held accountable for the phenomenon and many experiments have been brought forward to support the view, but the most recent work indicates that the kidney in all probability has no internal secretion and the older work in partial nephrectomy, ligation of ureters and administration of extracts of kidney, has been held to be insufficient to prove the point.

That some toxic agent is at work cannot be denied, and numerous recent writers consider that it is in the nature of a specific lysin for kidney substance—a nephrolysin. That nephrolysins can be produced by artificial immunization of animals is quite true, but that they are absolutely specific for the kidney is open to grave doubt, and according to most observers their administration is attended by distinct lesions of other tissues, including the blood. The production of autonephrolysins, that is, by the animal for its own kidney, fails of conclusive demonstration. Nevertheless, it has been shown that the serum of nephritic dogs contains a substance which on injection into other dogs produces a true nephritis. It is suggested, however, that this fact be applied to the pathology of nephritis only after further evidence has been adduced to support it. As material accumulates on this subject it seems evident that if the toxin is a nephrolysin, it probably is not identical with the nephrolysin obtained by artificial immunization. That seen in nephritis must have a much higher degree of specificity than the experimental product.

The relation of uremia to gastro-intestinal conditions frequently is brought forcibly to the attention of the clinician. Whether the gastro-intestinal condition, or the uremia, is the primary event is as yet an unsolved problem. Some experimental workers think that uremia produces toxins that are excreted into the intestinal tract and that these are of irritant nature. Recent work in nitrogen metabolism indicates that a large percentage of nitrogen is eliminated into the intestine and reabsorbed, but as yet there is no definite evidence to indicate that this process is associated with any distinct toxic elements. If intestinal conditions can produce the toxemia which we know as uremia, no acceptable evidence has been adduced to prove it.

IV. METABOLISM, EXCRETION AND RETENTION IN NEPHRITIS WITH EDEMA

Explanations of edema in connection with nephritis call into play physical, physiologic and chemical observations. Of great importance to the clinician are hydremia and chlorid retention, for these two factors are capable of control in the diet of the patient. Experimentally, hydremia appears to be absolutely necessary to the production of edema, and clinically it is generally conceded that some degree of hydremia plays an important part.[1] Lesions in the vessel walls, whether depending on the hydremia or on some toxic substance, possibly an endotheliotoxin, also influence the condition. From the standpoint of chemistry the question of chlorid retention comes more prominently to the fore than in any of the other phases of nephritis. That chlorids are retained in cases of edema and that increased elimination of chlorids appears at the time of disappearance of the edema are well-established facts.

The chief point under discussion at the present time, as to whether the retention of chlorids or the retention of water is primary, remains an open question. If the retention of water be primary, it requires sodium chlorid to balance the osmotic pressure in the blood. If the sodium chlorid retention is primary, the same need for balance of osmotic pressure is felt and water is retained. If the sodium chlorid occurs particularly in the tissues, then the attraction of water to the tissues is easily explained by the same necessity for equalization of osmotic pressure. Numerous views have been expressed pro and con, and experiment has been adduced for and against, but the matter remains in a somewhat chaotic and distinctly unsatisfactory state.

V. VASCULAR HYPERTENSION AND CARDIAC HYPERTROPHY

From the chemical point of view, so little has been done on the question of heart hypertrophy and vascular hypertension in chronic interstitial nephritis that it requires little discussion. Granting that the internal secretion of the kidney is a problematic factor we must turn to retained toxic substances or to the influence of other internal secretions, particularly that of the adrenal, for the explanation. Experimental, anatomic and physiologic work have appeared to throw some light on this phase from time to time, but as new facts have been brought out old ones have been controverted or minimized and to-day none of these branches of pure science can offer much for the satisfaction of the eager clinician.

What has been presented in this brief communication represents the results of years of ardent and careful work on the part of clinicians and laboratory men, working either separately or hand in hand. If there remains much to be learned, that does not minimize what has already been well established. As methods are improved and observation and deduction become more accurate, the results will become more applicable to the living human patient.

In this review I have drawn freely on the works of Von Noorden, Pearce, Bainbridge and Beddard and others, in addition to the most recent articles in current medical literature.

1320 South Broad Street.

---

[1] Edema has been produced recently without introduction of excess of water into the animal, but this does not exclude hydremia as an essential factor in the development of the condition.

CLASSIFICATION OF DIPHTHERITIC CONJUNCTIVITIS

REPORT OF A CASE WITHOUT MEMBRANE FORMATION *

HARRY FRIEDENWALD, M.D.

BALTIMORE

The following case is reported because of the very severe catarrhal conjunctivitis due to diphtheria bacilli, which ran its course without the development of a membrane.

History.—The patient, a physician, aged 56, consulted me Jan. 25, 1908, for a very mild conjunctivitis of the right eye, the left being unaffected. The eye had been uncomfortable since the day before and he feared that some irritant like formaldehyd solution had caused the trouble. The irritation was chiefly in the inner canthus.

Course of Disease.—A 5 per cent. solution of argyrol was ordered but the condition did not improve and rather increased in severity.

January 27: Some of the secretion was sent to a bacteriologist, who reported that it contained bacilli but he was unable to determine them from the slide specimen.

January 29: The lids became greatly swollen and the eyes teared profusely. There was no purulent solution. The patient now complained of some discomfort of the nose and throat and a prominent rhinologist examined them and reported congestion of the pharynx and tonsils. The right tonsil was more prominent and there was an indistinct yellowish line near the posterior pillar in the long axis of the tonsil. Two prominent colleagues were called in, who likewise were unable to account for the ocular condition and its resistance to treatment.

January 30: The condition remained almost the same, the temperature being slightly elevated to 100 F. The patient was somewhat depressed, which was attributed to worrying about his condition. The pathologist suggested that the organism which had been handed to him was suggestive of diphtheria and he requested a smear from the edge of the lid. This was taken, as was one from the pharynx, and I may say that while the smear from the edge of the lid did not develop any organisms, the pharyngeal smear gave a typical growth of the diphtheria bacilli, and the pathologist was convinced that the organisms in the first slide were identical with these. The membranous rhinitis and pharyngitis meanwhile increased and large masses were subsequently thrown off.

January 31: The condition was as follows: There was no membrane formation in the conjunctiva of either lid. The edema of the conjunctiva of the eyeball was very marked, as was also that of the lids. The cornea showed considerable irregularity of the epithelium without any ulceration. This had been noticed a day before. Along the intermarginal space when examined with a magnifying glass a few very fine gray spots were seen which could not be rubbed off with a cotton pledget. On this day, 2,000 units of antitoxin were given and in the evening 5,000 more. Within the next two days additional quantities of antitoxin were injected, making a total of 40,000 units.

---

* Read at the joint meeting of the Sections on Clinical Medicine and on Ophthalmology, Baltimore City Medical Society, Jan. 20, 1911.

February 1: Cultures taken from the eye were negative to diphtheria but showed staphylococci. The patient's condition improved after the use of antitoxin.

February 6: The temperature was normal; there was diminution of the secretion.

February 7: The nose began to give trouble and there was nosebleed; at this time the eyes again became more painful.

February 9: On this date I observed a faint superficial opacity running across the anterior of the cornea. The patient was now treated locally with argyrol and later with dionin, and the cornea became clearer though the central opacity remained. In the meantime the vision became almost half normal.

Subsequent History.—During the following June, the eye became congested and painful, and there was again breaking down at the side of the ulcer. The inflammation became rather intense and some hypopyon developed. Several weeks were required for recovery.

The peculiar course of this disease and the finding of the diphtheria bacillus in the fauces and the discovery of the same bacillus in the smear, though at first not recognized as diphtheria, with the undoubted diphtheritic appearance of the nasal and pharyngeal inflammation, seem to establish this as a case of diphtheritic conjunctivitis without membrane formation, in spite of the absence of the more convincing tests.

The inflammation in this case, while resembling the conjunctivitis due to the Koch-Weeks bacillus or to pneumococci, differed clinically, especially at first, in the absence of mucous or purulent secretion, in the resistance to ordinary treatment and in the appearance of the minute spots along the intermarginal border. Later, mixed infection occurred, as is not uncommon. The age of the patient is exceptional. Noll[1] has reported a patient aged 61, but he was able to find only a very few reported cases in adults (Kasztan, whose patient was 23 years old; Zur Nedden, whose patient was 17 years of age; Jessop,[2] whose patient was 29 years of age; and Schanz).

In the case here recorded it seems probable that the eye was the primary seat of infection, for the earliest nasal and pharyngeal symptoms made their appearance several days after the onset of the conjunctival disease.

A number of attempts have been made to substitute a bacteriologic basis for that of the clinical appearance in the classification of conjunctival diphtheria. Schirmer[3] pleads that we call all conjunctival inflammations due to diphtheria bacilli, diphtheritic conjunctivitis, it matters not what the clinical picture. Fuchs[4] in his textbooks takes the same view, distinguishing between superficial and a deep necrotic form. Luedde[5] contends against the old classification. Jessop[2] goes further and suggests that all cases of conjunctivitis with membrane should be merged into one class called "membranous conjunctivitis" or "membranous ophthalmia." . . . He would "like to see the term diphtheritic conjunctivitis disappear, as it is most confusing." On the other hand, many writers still hold firmly to the old classification, foremost among them being Saemisch[6] in his monumental work.

It is clear that accurate diagnosis and treatment as well as prophylaxis demand that we do away with the confusion. There is no possible reason why we should use one nomenclature for the pharynx and another for the conjunctiva. The term "diphtheritic" should in the future be applied only to inflammations produced by the diphtheria bacillus.

CARBON MONOXID POISONING RESULTING IN GANGRENE OF BOTH LEGS

ANGUS McLEAN, M.D.
DETROIT

The ordinary clinical picture of carbon monoxid poisoning is almost too well known to demand description. Carbon monoxid is a gas which, being colorless and tasteless, is usually inhaled unconsciously. Most cases of poisoning occur during sleep. It is an exceedingly poisonous gas. The method by which it produces its direful and fatal effects is by forming with the blood coloring-matter a compound which is more stable than oxyhemoglobin.[1] The affinity of carbon monoxid for hemoglobin being 200 times greater than that of oxygen, it causes asphyxia by destroying the power of the blood-corpuscles to carry oxygen from the air to the tissues.

The symptoms encountered when a considerable amount of this gas has been inhaled are vomiting, languor, headache, debility, etc., leading to deep unconsciousness, with shallow breathing, rapid pulse, cold, clammy perspiration and, finally, death. With active treatment patients in extreme conditions often recover, but on account of the stability of the carbon monoxid compound formed with the blood coloring-matter, the symptoms of languor, etc., often are very persistent, lasting until the coloring-matter, rendered useless by the carbon monoxid, is replaced by a new formation. This time is very variable and may last from several days to several weeks, when the condition of the patient again gradually becomes normal. This gradual return to normal is not, however, always uneventful. Nervous symptoms, even simulating insanity,[2] cerebral hemorrhages,[3] usually occurring in the caudate nucleus and optic thalamus, hemiplegia,[4] nutritive changes in the brain and skin,[5] etc., all have been recorded as occurring after carbon monoxid poisoning in persons apparently normal up to the time of the accidental inhalation of the gas.

I report herewith a case of carbon monoxid poisoning, followed by a very stormy convalescence, characterized by a clinical picture which is rare—indeed unique, for nowhere in the literature of the last decade have I been able to find a similar report. The case is one in which the carbon monoxid poisoning was followed by gangrene of both legs, necessitating amputation. The history of the case is as follows:

J. H., male, aged 22, American by birth, was admitted to Harper Hospital Dec. 20, 1909. The patient's family and previous history were unimportant. There was no specific history. On the morning of Dec. 20, 1909, the patient was found unconscious in his bed in a room in which there had been burning a small gas-burner, from which the flame had become extinguished during his sleep. He was immediately sent to the hospital and on admission at 11 a. m. there were present profound unconsciousness, slow, shallow respiration and a rapid, thready, uncountable pulse. He had involuntary evacuations from his bladder and his body was covered with a cold clammy perspiration. Shortly after admission his temperature was 102 F. The leukocyte count, differential and absolute, was normal. The red blood-count was normal, but there was present a marked degeneration of red blood-cells, with a striking tendency to clumping, each clump with a nucleus of débris taking a deeper stain. The hemoglobin index was 40 per cent. The diagnosis was carbon monoxid poisoning. From inquiry at the chemical laboratory of the City Gas Company, it was determined that the gas inhaled by the patient was illuminating gas and that the most actively poisonous ingredient, carbon monoxid, was present in the proportion of 7 per cent. A lesser percentage will readily produce poisoning.[1] Forty-eight hours after admission, during which time stimulation, artificial respiration and oxygen inhalation had been resorted to almost continuously, the patient had regained sufficient consciousness to speak. His pulse and temperature gradually approached the normal. By the end of the fourth day he was able to sit up; on the fifth day he walked about a little. He was dismissed on the evening of the fifth day apparently in good condition, complaining, however, of pain in the feet and legs.

December 27, two days after leaving the hospital, he was again admitted on account of the increasing pain in the feet and legs. Examination showed that the legs and feet were swollen and slightly discolored in patches, the discoloration extending below the knees, somewhat higher on the right than on the left side. The limits of the discoloration were rather sharply defined. The discolored portions were cold, and sensation was practically absent. During the next two weeks the pain in the legs continued, at times being so severe that it necessitated the administration of opiates. The discoloration increased to gangrene, the dorsum of each foot being seemingly attacked last. The legs became edematous.

January 7, longitudinal incisions were made to determine the condition of the deeper tissues. These were found to be necrotic, with all the appearances of moist gangrene. Culture showed pure growth of *Staphylococcus aureus*. Up to this time the patient's condition was extreme; he was delirious at times, with an irregular temperature curve ranging between 101 and 105 F.; pulse 130 to 160, systolic blood-pressure 110 mm. The blood-picture showed a marked leukocytosis with 85 per cent. polymorphonuclear leukocytes.

January 9, the right leg was amputated, and January 13 the left leg. For the remaining part of January the patient's condition was very critical. Bed-sores developed over the sacrum and on either buttock. The flaps of the left stump sloughed away. There was profuse sweating practically all the time. January 16, the blood examination showed hemoglobin 55 per cent. The red cells numbered 4,376,000, but were degenerated and very pale. The leukocytes were diminished in number. The blood itself was very watery and showed practically no tendency toward clotting.

About the middle of February the patient began to improve generally and the stumps showed evidences of granulations around the skin margins. On March 19 he was anesthetized (ether narcosis) and the stumps were trimmed; the right tibia and fibula were disarticulated at the knee-joint, and a portion of the condyles of the left femur were removed. From this time convalescence was uneventful; the stumps made good progress, being almost completely closed over at the time of his dismissal one month later.

The patient was dismissed April 15, 1910, practically four months from the time he was asphyxiated.

This case demonstrates that the effects of carbon monoxid poisoning are more far-reaching than is generally supposed. It also demonstrates that although recovery may be apparently complete, yet after the lapse of a few days or (as in some cases reported in the literature, reference to which will be appended below), even a few weeks the most startling and irreparable damage to the human organism may become evident as a result of the inhalation of this gas.

The question naturally arises: What is the exact pathologic condition which occasions such a wide-spread destruction of tissue, as, for instance, gangrene of both legs in the case above reported? In this case diabetic gangrene, chemical gangrene, senile gangrene and gangrene from exposure to extremes of temperature can all be excluded. Thrombotic and embolic gangrene, too, can be excluded, at least in this case, as after a careful search for thrombi and emboli our findings were negative. Some writers, however, report cases of thrombosis[6] following carbon monoxid poisoning. Such a case occurred in the practice of Dr. William J. Seymour some years ago.

A man aged 45, entered St. Mary's Hospital, Detroit, unconscious from carbon monoxid poisoning. He remained unconscious for about twenty-four hours, after which he complained of headache, stupor and a general languid feeling. On the fifth day he complained of considerable pain in his left arm, after which the hand and forearm became immensely swollen and edematous. This condition of pain and swelling persisted for about four weeks; then it gradually subsided. The diagnosis here was thrombosis of the axillary vein.

There certainly was no such picture in my case. Besides, if due to thrombosis, the gangrene would more probably have been unilateral. What then was the condition to which the gangrene in this case could be attributed? Was it an angioneurotic gangrene—the poison having affected the trophic nerves or the trophic cells in the anterior part of the cord, causing degenerative changes, thus disturbing their functionating power, which became manifest first by an angiospastic anemia, or, as Weiss[7] calls it, a "regional ischemia," resulting finally in gangrene? Or was it due to the constitutional, or rather the general, altered condition of the blood, the nutritive powers of which had been so enormously diminished by the sudden formation of the carbon monoxid-hemoglobin compound, that the parts in which normally the circulation is poorest, i. e., the lower extremities, would naturally become affected first?

Of the first proposition I can say but little definitely, for I had no way of determining whether or not the degenerative changes really did take place in the trophic nerve-cells or their fibers. Any conclusion I could draw from this as to the primary pathologic condition causing the gangrene in the extremities would, therefore, at best be but problematical.

As to the second proposition, the altered nutritive value of the blood, we know that the hemoglobin is the oxygen-carrier of the blood, and that this oxygen carried by the blood is absolutely essential to the life of the body tissues. If, for some reason or other, the normal supply of oxygen is disturbed and a sufficient amount prevented from coming into contact with the tissues, these will suffer and, depending on the amount of oxygen of which they are deprived, gangrene or other nutritive changes will result. Such is the condition which it seems we had to contend with.

---

[6] Hirnblutung und Erweichung bei CO Vergiftung, Strassb. med. Ztg., 1909, vi, 165.

[7] Korsakoffsches Syndrom bei CO Vergiftung, Berl. klin. Wchnschr., 1908, xlv, 1621.

Hemoglobin, once converted into carbon *monoxid* hemoglobin, is useless for the body economy. This compound is stable and for this reason oxygen can never displace the carbon monoxid. After carbon monoxid poisoning, the normal oxygen supply to the body will take place only when a new supply of hemoglobin has been furnished; in other words, the tissues must wait for their normal oxygen supply until such a time as the body will again be able to furnish or manufacture, if you will, a sufficient supply of hemoglobin to carry the oxygen to its different parts. If, in the first place, the amount of carbon monoxid inhaled is so great as to combine with all the hemoglobin of the blood, the condition resulting (i. e., 100 per cent. carbon monoxid hemoglobin, 0 per cent. hemoglobin or oxyhemoglobin), is incompatible with life and the patient dies immediately. If, on the other hand, the amount of carbon monoxid inhaled is such that it combines with only part of the hemoglobin of the blood, the condition resulting (say, 50 per cent. carbon monoxid hemoglobin and 50 per cent. hemoglobin or oxyhemoglobin), is such that the patient will live, but the tissues will not receive the necessary supply of oxygen for the performance of their normal functions. This insufficient supply of oxygen will continue until the time when the new formation of hemoglobin can take place. During this time, the hemoglobin which is free from carbon monoxid must supply the oxygen to the tissues as best it can. The amount thus supplied may be sufficient to sustain life in every part of the organism. If it falls short of this, the parts in which circulation normally is poorest will first show the effects of insufficient oxygenation. This condition, I think, is well illustrated in the case reported. Here, hemoglobin, sufficient to cause grave constitutional disturbance and death of both extremities (the parts normally sparingly supplied with blood), but not sufficient to cause the death of the organism, was rendered inert by the formation of the stable carbon monoxid hemoglobin compound.

According to experiments by Nasmith and Graham[8] made on guinea-pigs, the time for the new formation of hemoglobin is variable, three to four weeks usually elapsing before the oxygen-carrying power of the blood again becomes normal; i. e., before compensation takes place by an increased number of red blood-cells and hemoglobin content. At the end of this time the irreparable damage, as in the case reported, will have been done and the best that can then be expected from the compensation is to improve the vitality of those parts which have not been starved beyond repair: in other words, which have *not gone on to the stage of gangrene.*

This explanation of the gangrene following carbon monoxid poisoning seems plausible to me. Sufficient proof, however, is not at hand to determine this fact definitely. Yet, on considering the exact mode of onset in this case—how the gangrene did not commence at the toes and travel progressively upward, but how islands of comparatively healthy tissue were left in which vitality seemed to persist longer than even some more proximal parts—on considering other cases of gangrene of the skin reported, in which the gangrenous patches were usually distributed irregularly over the body where the activity of the peripheral circulation is often impaired even normally, I feel more than ever that the diminished nutritive value of the blood brought about by the formation of carbon monoxid hemoglobin is the most probable cause of the localized gangrenous condition.

A NEW METHOD OF COUNTING THE BLOOD-PLATELETS FOR CLINICAL PURPOSES

AND SOME OF THE RESULTS OBTAINED WITH IT [*]

JAMES HOMER WRIGHT, M.D.

AND

ROGER KINNICUTT, M.D.

BOSTON

A number of methods[1] have been employed for estimating the number of blood-platelets per cubic millimeter of blood, but none of them has seemed to us practical or satisfactory for clinical purposes. A new method has therefore been devised, and it is as follows:

The blood is mixed with a diluting fluid in the proportion of 1 to 100 by means of the pipette used for counting red blood-corpuscles, and the counting is done in an ordinary blood-counting chamber with a high power dry objective. In order to render the platelets more clearly visible, the specially thin cover-glass of Zeiss, with central excavation, is used (cover-glass No. 146, Zeiss catalogue). This may be obtained from Eimer & Amend, 205 Third Avenue, New York. The diluting fluid consists of two parts of an aqueous solution of "brilliant cresyl blue" (1:300) and three parts of an aqueous solution of potassium cyanid (1:1,400). These two solutions must be kept in separate bottles and mixed and filtered immediately before using. Of course, the pipette should be well shaken before withdrawing the sample for counting. After the counting chamber is filled it is left at rest for ten or fifteen minutes in order that the blood-platelets may settle to the bottom of the chamber and be more easily and accurately counted.

---

[*] From the Pathological Laboratory of the Massachusetts General Hospital.

[1] The methods and observations of most other workers *in this* field are well described and summarized in the papers by J. H. Pratt (A Critical Study of the Various Methods Employed for Enumerating Blood-Platelets, THE JOURNAL A. M. A., Dec. 30, 1905, p. 1999), and by Kemp, Calhoun and Harris (The Blood-Plates: Their Numeration in Physiology and Pathology, THE JOURNAL A. M. A., April 7, 1906, p. 1022, and April 14, 1906, p. 1091).

References not given in these papers are: Howlett: Lancet, London, 1882, i, 223. Osler: Medical News, April 3, 1886, p. 365. Eschistowitsch: Folia hæmotol., Berl., iv, 295. Cadwalader: Bull. Ayer Clin. Lab. Penn. Hosp., No. 3, 1906, p. 50.

The platelets appear as sharply outlined, round or oval, or elongated, lilac-colored bodies, some of which form a part of small spheres or globules of hyaline, unstained substance.

The red cells are decolorized and appear only as "shadows," so that they do not obscure the platelets. The nuclei of the white cells are stained a dark blue, the protoplasm light blue. If the technic is correct there should be no precipitate in the preparation.

The cresyl blue solution is permanent, but should be kept on ice in order to prevent the growth of yeasts. The cyanid solution should be made up at least every ten days. It is, of course, necessary that the solution be made from pure potassium cyanid, which has not undergone decomposition. As already stated, the two solutions must be mixed and filtered immediately before using, because after filtration, if the mixture is allowed to remain exposed to the air for a short time, a precipitate will form in it. After the diluting fluid has been mixed with the blood in the pipette, however, no precipitate forms and, as the platelets do not quickly break up in the mixtures, the counting may be done after some hours, if necessary. For example, a count immediately after filling the pipette was 258,000, and another count from the same filling of the pipette made eighteen hours later was 253,000.

A proper technic yields a remarkably even distribution of the platelets in the chamber. For all practical purposes the counting of the platelets in 100 small squares is sufficient, but for greater accuracy all 400 small squares should be counted, or 200 small squares in each of two fillings of the chamber.

Table 1 is a sample count showing the even distribution of the platelets in the counting chamber:

TABLE 1.—PLATELETS COUNTED IN A ROW OF TWENTY SMALL SQUARES

—Chamber 1.—		—Chamber 2.—	
22	21	21	25
27	28	21	23
27	24	27	22
23	30	22	25
21	21	23	31
120	124	120	126

By our method the platelet count of normal adults is found to vary from 226,000 to 367,000 per cubic millimeter, the general average being 297,000. Table 2 is a table of counts of normal individuals, all adults males.

TABLE 2.—COUNTS OF BLOOD-PLATELETS IN NORMAL INDIVIDUALS

Normal Individuals.	No. of Counts.	Over period of	Average.	Highest.	Lowest.
A	23	1 year	272,000	328,000	226,000
B	5	2 weeks	336,000	367,000	297,000
C	2	1 week	305,500	319,000	292,000
D	4	10 days	263,500	272,000	252,000
E	2	1 week	332,000	347,000	317,000
4 individuals, 1 count each			273,250	330,000	224,000

The objection has been made to the methods of platelet enumeration involving the use of a mixing pipette, that the counts obtained by them are too low because many of the platelets stick to the glass of the pipette and thus escape observation. We do not think that this objection applies to our method, for the following reasons:

1. When blood and, immediately afterward, the diluting fluid are drawn up into a capillary pipette, microscopic examination does not reveal any platelets sticking to the glass.

2. Our normal counts range higher than those of all other observers who have employed methods involving the use of a pipette, except one. Thus, the highest count among the large number of counts contained in the reports of Cadet and others is only 310,000. The exception is the count of *"kaum ½ million"* stated by a reviewer to have been found by Prus for normal blood in contrast to 2,000,000 for leukemic blood. This inexact numerical expression might very well mean a count, or counts, for normal blood not greatly in excess of our own. Van Emden, however, used Prus' method and obtained normal counts which do not range as high as our own. He attributed Prus' apparently high normal figure to fragmentation of the blood-cells by too much shaking of the pipette.

3. Our normal counts do not differ significantly from those obtained by several observers who used methods based on the determination of the ratio between the platelets and the red corpuscles. Thus, Pizzini obtained figures varying from 250,000 to 370,000 among fifty-seven counts made on seven healthy persons to determine the possible effect on the numbers of the platelets produced by digestion, heat, cold and fatigue; Determann among twenty-five normal bloods found counts varying from 180,000 to 250,000, if we assume that the red corpuscles count for each was 5,000,000; and Cadwalader, in nine counts on two normal persons, found 259,360 to 400,000 the average being 348,000.

Certain other observers, however, working with ratio methods, have reported higher normal counts than those just mentioned, but we believe that their methods were erroneous and that their results are not reliable.

Thus, Brodie and Russell used a diluting fluid consisting largely of glycerin, which is destructive to red corpuscles, and therefore the ratios which they obtained are obviously not to be relied on as being the true ones.

Kemp and Calhoun report twenty counts from thirteen normal persons, ranging from 730,000 to 962,000. In a later paper, however, they report that they found fifteen ratios of platelets to red corpuscles in five normal men, determined on the same three successive days, to vary from one to eighteen to one to twenty-three, which, on the basis of 5,000,000 red corpuscles to the cubic millimeter, would represent counts of only about 217,000 to 270,000. Such a marked discrepancy between these two sets of counts seems to us to be sufficient to discredit their method and the high counts which they obtained with it.

J. H. Pratt found in seven normal individuals counts agreeing with ours (226,000 to 377,000), but in eighteen others his counts vary from 416,000 to 725,000. In view of the results of other workers, this seems to us to be a wider degree of variation in normal individuals than can be accounted for by any supposed superiority in his method, and we therefore believe that these higher counts should not be accepted.

4. The closeness of successive counts from the same individual and the high counts obtained in certain diseases are also good evidence. For example: 257,000, 271,000 and 263,000 from a normal individual; 698,000 and 708,000 from a case of hemophilia; and 1,130,000 and 1,077,000 from a case of anemia after hemorrhage. These results seem to us to be incompatible with any important loss of platelets by sticking to the glass. If there be a loss of platelets, it must be a constant factor which does not vitiate the usefulness of our method for determining the fluctuations in the numbers of the blood-platelets.

We have counted the platelets by this methods in a considerable variety of diseases, studying especially their numbers in anemia, in typhoid fever and in pneumonia, and the results obtained are summarized below. Our observations fully confirm those of Hayem and others in the three diseases mentioned.

In secondary anemia we have found the blood-plate count to be generally high, while in pernicious anemia we have found it to be always low at some period of the disease. Thus, in seven out of nine cases of secondary anemia, counts above 400,000 were obtained, while in none of the cases was a count below normal found. The highest counts were 1,130,000 and 1,162,000 obtained in two cases due to hemorrhage. On the other hand, in nine cases of pernicious anemia the twenty-three counts made varied from 20,000 to 161,000 while the tenth case showed a count of 381,000, which fell to 172,000 ten days later.

In view of these observations, it would seem that the platelet count will prove to be of material assistance in distinguishing between the two forms of anemia in doubtful cases.

This contrast between the two forms of anemia in the platelet content of the blood is readily explained by the following considerations: It is well known that in secondary anemia an hyperplasia of the red marrow of the bones takes place sooner or later and thus an increase is brought about in the number of the marrow giant cells, the megakaryocytes, which have been shown by one of us,[2] to produce the blood platelets by the fragmentation of their cytoplasm. Consequently, the number of the platelets in the blood is increased. On the other hand, the diminution in the number of the platelets in the blood of pernicous anemia is explained by the observation of one of us that the peculiar red marrow of this disease, although greater in amount than normal red marrow, regularly does not contain as many giant cells as does normal red marrow or the hyperplastic red marrow of secondary anemia.

In two cases of chlorosis, normal counts were noted, while in a case of splenic anemia a count of 75,000 was obtained.

In three out of four cases of lymphocytic leukemia, one being of the large cell type, the counts were lower than normal, ranging from 37,000 to 130,000. We attribute the low counts to lymphomatous transformation of the bone marrow, with consequent reduction in the number of marrow giant-cells.

In two cases of myelocytic leukemia the counts were high, varying from 595,000 to 860,000, while in one case the count was normal. In this connection it is of interest to note that while the leukocyte count in one case fell from 385,000 to 161,000 under x-ray treatment, the blood-platelet count, which had been 860,000, remained high, 771,000. This observation constitutes additional evidence that the blood-platelets are not closely related to the leukocytes, or to their parent cells of the bone marrow, the myelocytes.

Forty-four counts in all were made in seventeen cases of typhoid fever. The results show that in the beginning of the disease the number of the blood-platelets is below normal or a low normal, but as the disease progresses their number increases and during convalescence may be very high, in one case reaching 759,000. In two cases of relapse the platelet count became low after having been normal or high, becoming again normal or high in convalescence.

In lobar pneumonia during the progress of the disease the number of the platelets may be low, normal, or slightly above normal, but at or soon after the crisis it increases very rapidly and in one case reached 944,000. In a case in which empyema developed the counts rose to 714,000 and 813,000 during this complication, while during the pneumonia they were 229,000 on two occasions.

In two cases of malaria there were low counts. In one of them the count was 143,000, but six days after quinin treatment had begun it had risen to 449,000.

In a case of hemophilia with persistent epistaxis and purpura, the count was 125,000 on July 2 and 337,000 on August 17, but fell to 27,000 three days later. Another count made after the lapse of some months was 87,000. In another case of hemophilia, however, the count was high, being 698,000, and 708,000 three days later. A case of Henoch's purpura also showed high counts (508,000 to 645,000 in five counts during sixteen days).

In a child with chronic bloody diarrhea due to ulcerative colitis, five counts made in the course of three weeks varied from 18,000 to 62,000.

The platelet counts of a man who had been drunk for about two months and had eaten but little, was of special interest. He entered the hospital with delirium tremens, bleeding from the gums and symptoms suggestive of scurvy. He also had cirrhosis of the liver. Two days after entrance the count was 136,000. Under feeding and the administration of orange juice he rapidly grew better and the counts taken at intervals of one or two days were successively, 141,000, 160,000, 187,000, 270,000, 365,000 and 350,000.

Counts made in other diseases were as follows: infectious polyarthritis, two cases, 518,000 and 641,000; pleurisy with effusion, two cases, 628,000 and 335,000; streptococcus septicemia, 456,000; chorea, 445,000; "Hodgkin's disease," 458,000; gangrene of the gall-bladder, 221,000.

The relation of the number of the blood-platelets to the number of the leukocytes in the same blood has also been studied. By using a counting-chamber with a Türck ruling, we have been able to make leukocyte counts parallel with the platelet counts in the same chamber, the counting being facilitated by the staining of the leukocytes. In this way 164 leukocyte counts of widely varying figures were obtained and compared with the platelet counts in the same cases. The results clearly show that variations in the number of the platelets and in the number of the leukocytes have no constant relation to each other. This is a further evidence that the blood-platelets are not derived from the leukocytes, as some writers have believed.

For Honest Advertising.—"The action of the federal authorities in excluding offending newspapers from the mails protects only a part of the readers of fraudulent advertisements. There should be state legislation holding publishers accountable for printing the palpably dishonest advertisement swindles, and of all other unscrupulous advertisers who seek to betray the reader's confidence in the integrity of the press." Above is the concluding paragraph of Governor Osborne's inaugural message to the legislature. It is given prominence here for the reason that no Detroit daily newspaper has printed it, with the exception of the *Times*, and we believe it merits the widest possible publicity. Dishonest advertising is eliciting increasingly courageous criticism from the more reputable journals throughout the country.—Detroit *Saturday Night.*

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

COLLOIDAL SILVER PREPARATIONS[1]

Under certain conditions involving a very fine state of subdivision, metallic silver and some of its compounds ordinarily insoluble appear to become soluble in water. These preparations are not precipitated by the ordinary precipitants of silver salts. Consequently they can be mixed with organic liquids or injected into the tissues or even into the bloodstream without precipitation and without causing marked symptoms or irritation. They possess to a greater or less degree the antiseptic properties of solutions of silver.

CARGENTOS.—Argenti Oxidum Colloidale, Mulford.—Colloidal Silver Oxide, Mulford.—Cargentos is claimed to be a preparation of colloidal silver containing 50 per cent. of metallic silver in the form of oxide, together with a sufficient amount of modified casein to maintain the silver oxide in colloidal form when in solution.

Cargentos is prepared by precipitating an alkaline solution of silver caseinate and silver oxide by an acid, dissolving the precipitate in an alkali, dialyzing the resulting solution against running water and evaporating the remaining colloidal solution to dryness in vacuo.

Cargentos occurs in odorless and tasteless black scales of metallic luster. It is freely soluble in water and glycerin. Solutions of cargentos are reddish brown by transmitted light and greenish black by reflected light. Solutions of cargentos should be prepared with cold water and kept in dark colored bottles.

Its solutions are not precipitated by sodium chloride nor by albumin in the secretions.

Cargentos, when assayed by the following method, should be found to contain silver equivalent to 48 to 52 per cent.

0.3 to 0.5 Gm. cargentos is weighed into a crucible, ignited gently at first, afterwards with full flame of a bunsen burner, until the ash is light in color.

The residue is treated with concentrated nitric acid and if completely dissolved the solution is diluted with 50 Cc. water, 2 Cc. ferric ammonium sulphate solution added and directly titrated with tenth normal potassium sulphocyanate. If after treating with nitric acid an insoluble residue of silver chloride remains, it is collected on a filter, washed with water, dried, ignited and weighed as silver chloride; the silver content of the filtrate is determined by titration with tenth normal sulphocyanate as before and the silver so found is added to that obtained in the silver chloride.

Actions and Uses.—Cargentos is claimed to possess considerable germicidal power and pronounced penetrating properties. It is said to be non-irritating even in 50 per cent. solution.

It is said to be useful as a substitute for the ordinary compounds of silver in treatment of inflamed mucous membranes and as an intestinal antiseptic. It may be used in 50 per cent. solutions for the purpose of producing a shadow in Roentgenographic examinations.

Dosage.—For application in diseases of the eye and of the genitourinary organs 5 to 25 per cent. solutions; for application to other mucous membranes 10 to 50 per cent. solutions may be used. Freshly made solutions are always to be preferred.

Manufactured by H. K. Mulford Company, Philadelphia. Process patent applied for. Not trademarked.

Cargentos Tablets.—Colloidal Silver Oxide, 3 grains, Mulford.—Each tablet contains cargentos 0.195 Gm. (3 grains) without excipient.

To prepare a solution the tablet should be crushed and powdered, sprinkled on the required quantity of cold water and allowed to stand for about 5 minutes and then agitated until solution occurs.

Cargentos Rectal Suppositories.—Colloidal Silver Oxide Rectal Suppositories, Mulford.—Each suppository weighs 1.25 Gm. (19¼ grains) and contains cargentos 0.130 Gm. (2 grains) in a vehicle consisting of oil of theobroma together with a sufficient quantity of yellow wax.

Cargentos Vaginal Suppositories.—Colloidal Silver Oxide Vaginal Suppositories, Mulford.—Each suppository weighs about 6.4 Gm. (98½ grains) and contains cargentos 0.325 Gm. (5 grains). The vehicle consists of oil of theobroma together with a sufficient quantity of yellow wax.

Cargentos Urethral Suppositories.—Colloidal Silver Oxide Urethral Suppositories or Bougies, Mulford.—Each suppository weighs about 2.5 Gm. (37 grains) and contains cargentos 0.130 Gm. (2 grains). The vehicle consists of glycerite of boroglycerin, gelatin and water.

OVOGAL—Albumen Cholicum.—Ovogal is a combination of bile acids with egg albumen.

Ovogal is a greenish-yellow powder, insoluble in water, dilute acids, ether, benzol, fats, etc. Alcohol and acetone do not dissolve it, but after long action remove from it small amounts of the bile acids. Alkalies dissolve ovogal, splitting it into albumen and bile acids (glycocholic and taurocholic acid).

If 0.5 Gm. of ovogal is boiled with 1 to 2 Cc. hydrochloric acid until a clear green solution is produced and then diluted with from 30 to 40 Cc. of absolute alcohol an abundant cloudy precipitate separates, which when washed with alcohol until the washings are colorless, gives the characteristic reactions for proteins. On evaporation of the alcoholic filtrate, the bile acids may be recovered and identified. Ovogal on ignition should leave no weighable residue.

Actions and Uses.—Ovogal is said to pass the stomach without marked decomposition and to be dissolved and absorbed in the intestine.

For therapeutic indications see Bile Salts.

Dosage.—0.5 to 1 gm. (8 to 15 grains) several times daily in capsules with water, tea, coffee or fruit juices.

Manufactured by J. D. Riedel A. G., Chemische Fabriken, Berlin, Germany. (Riedel & Co., New York.) Not patented in U. S. German patent No. 176,945. U. S. trademark No. 78,352.

Ovogal Capsules.—Each capsule is said to contain ovogal 0.5 Gm. (7½ grains).

XERASE.—Xerase is a mixture of a specially prepared dry beer yeast 150 parts, grape sugar (dextrose) 20 parts, white bole 125 parts and a mixture of nutritive salts 3 parts.

Xerase is a yellowish-gray powder, having a weak odor of yeast and a salty taste. It is only slightly soluble in water. It resists ordinary atmospheric conditions.

Actions and Uses.—This mixture is absorbent on account of the bole and readily induces fermentation which is favored by the sugar and salts and it is claimed that the yeast has a bactericidal action on such organisms as the gonococcus. It is said to adhere readily to mucous membranes.

It is claimed that this mixture is useful in inflammations and ulcerations of the vaginal and cervical mucous membranes and in the treatment of putrid wounds, ulcers, inoperable carcinoma, etc. It may be applied as a powder by insufflation or inserted into the vagina in a gelatin capsule.

Manufactured by J. D. Riedel Aktiengesellschaft, Berlin, Germany (Riedel & Co., New York). Not patented in the United States. U. S. trademark applied for.

Xerase Capsules.—Each capsule contains about 3 Gm. (45 grains) of Xerase.

Therapeutics

TYPHOID FEVER

VACCINATION AGAINST TYPHOID FEVER

The demonstration of the important relation which bacilli bear to typhoid fever led shortly to the query as to whether by cultivation of the bacilli any product could be obtained which might be successfully used in the treatment of the disease or in its prevention.

The studies of Haffkine, in India, with reference to obtaining a substance which could be used for prophylactic inoculation in the prevention of cholera, led to similar investigations in regard to typhoid fever. These were taken up by Pfeiffer, in Germany, and in London by Sir Almroth E. Wright; and to Wright especially do we owe the development of the present system of antityphoid inoculation.

---

[1] In accepting Cargentos, the Council has voted that a general article on Colloidal Silver Preparations be inserted in N. N. R. and Cargentos and Collargol be placed under it.—W. A. PUCKNER, Secretary

The vaccine used for preventive inoculations is prepared by cultivating a strain of not very virulent typhoid bacilli. These are destroyed by heat and have added to them a small amount of an antiseptic to prevent contamination with aerobic microorganisms. It is customary to standardize the solution so that 1 c.c. will contain 1,000,000 of the bacilli. This is the usual dose administered, although sometimes half the quantity is used. The vaccine retains its strength for at least three months, and it has been found in some cases to retain its efficiency for fifteen months. It is used by hypodermatic, not intramuscular, injection and is usually given in the arm, but it may be given under the skin of the abdomen. It is usually advisable to repeat the dose after ten or twelve days in order to get the maximum amount of protection from the inoculation. Following the first dose there is a varying amount of reaction. This may be indicated locally by redness of the skin, which may vary from a patch three or four inches in diameter to one that extends down the forearm and to the shoulder. The axillary glands may be enlarged.

Accompanying this local reaction there may be a constitutional reaction which may vary from slight indisposition in mild cases to chills, with an elevation of temperature to from 101 to 103 F., with aching throughout the body, accompanied sometimes by a headache—symptoms such as accompany the onset of a severe cold or influenza. Rarely is there nausea or diarrhea.

After the subsidence of the local manifestations there may remain a slight nodule, which, however, disappears in about two weeks, *leaving no mark to show where the* vaccination has been done.

The constitutional symptoms appear in two or three hours in mild reactions, and disappear in from twelve to twenty-four hours; in severe reactions the symptoms last for from forty-eight to seventy-two hours. In children, the constitutional symptoms are usually less marked than in adults.

A great deal has been said about the so-called negative phase. This has reference to an increased susceptibility to typhoid fever during the first two or three weeks after the inoculation has been made. The alleged presence of this so-called negative phase has been used as an argument against the general adoption of the inoculations, but Wright has demonstrated conclusively that this may be prevented by avoiding a large dose, and the dose of one billion bacilli is not so large as to cause this temporary increased susceptibility to the infection.

The injections are best given in the late afternoon, so that the patient may retire early in the evening, and the greater part of the unpleasant symptoms from the reaction, in a mild case, may disappear during the following morning.

A considerable number of statistics have been reported by various observers, and especially through Wright, of England, concerning the results of these inoculations in various parts of the world, and especially in the British and United States armies. Comparing, in the same regiment or groups of regiments, the men who have been inoculated with those who have not been inoculated, it has been observed uniformly that fewer cases of typhoid fever have occurred among the inoculated men than among those who have not been inoculated. Still more striking is the observation on the mortality of typhoid fever. The mortality of the small proportion of inoculated men who suffer from typhoid fever is very much less than the mortality among the uninoculated men.

These various statistics would seem to prove conclusively the usefulness of inoculation in diminishing the number of cases of typhoid fever, and still more in diminishing the mortality among those affected with the disease.

What is the significance of the facts thus set forth to the general practitioner? Is it his duty to advise all who consult him to subject themselves to antityphoid vaccination? Does he not show himself guilty of negligence which is deserving of severe criticism, if he does not do so? Certainly, to-day neither the members of the medical profession nor the citizens of the country have been educated up to the point where the conscientious physician can reasonably be expected to advise his patients to submit to antityphoid inoculation, however thoroughly he may be convinced of its usefulness. With regard to certain classes in the community there can be no question of the advisability of these inoculations. It is recognized by all that the disease occurs with the greatest frequency among youths and young adults. Consequently, it is with reference to these that the problem is most urgent.

One class of young adults with regard to whom the sentiment is pretty well formed that vaccination should be done, consists of soldiers who are about to engage in war. As is well known, typhoid fever is especially prevalent in armies during military campaigns; consequently, all soldiers who are about to enter on a campaign should receive inoculations, and at present a large number of them are getting it.

Perhaps the next class in the community which is especially exposed to the danger of contracting typhoid fever includes the permanent attendants on sick people in general hospitals, viz., the nurses, the orderlies, and the resident medical staff. It may be fairly said that at present those in authority are liable to be censured if they do not insist on these individuals receiving typhoid inoculations, unless it may be those in hospitals where typhoid fever is never treated. How many such hospitals are there?

Perhaps the next classes to be considered are young men and women who leave home to go to college or boarding school, people who make long trips away from home, and people who take summer recreation trips. As is well known, typhoid fever is common among the people of these classes, and it would no doubt be wise if all such persons should submit to antityphoid vaccinations before leaving their homes. Were this done, unquestionably many cases of the disease would be prevented, and many deaths avoided.

Finally, taking up the rest of the community, there seems to be no reason to doubt that, except in those parts of the country where typhoid fever is unknown and where the people never leave their homes, it would conduce to the avoidance of the disease and the prevention of death from it, if everyone submitted to an inoculation.

The period during which the protection against the disease persists is not definitely established. It seems to be pretty well proved that the protection is effective for at least two years, and there is very strong reason for believing that a considerable degree of protection, though not so complete protection, is afforded for many years, or even during the rest of the individual's life.

When sanitation has entirely stamped out the disease, these inoculations of course will be superfluous; until that time arrives there is every reason to believe that they will be advised with increasing frequency by conscientious physicians and will be increasingly demanded by people who intend to avoid sickness and death from typhoid fever.

THE SPECIFIC TREATMENT OR SEROTHERAPY OF TYPHOID FEVER

Thirty or forty years ago, at the time when Ziemssen's monumental cyclopedia of medicine became known to American readers, the term "specific treatment" as applied to typhoid fever was used to indicate the administration of large doses of calomel during the early part of the disease. Since the discovery of the *Bacillus typhosus* and the active work of bacteriologists on typhoid fever, the term has been applied to those forms of treatment in which it was attempted to make use of a serum in the treatment of the disease.

No treatment of this character at all comparable to the serum used in the treatment of diphtheria has, up to the present, been found for typhoid fever, although great effort has been expended in trying to discover such a serum.

The one concerning which the most favorable reports have been made and which seems to have accomplished the most is that used by Chantemesse, of Paris. He began the administration of his antityphoid fever treatment in 1892, but his results were not successful until, in 1899, he produced a soluble typhoid toxin. From this he was able to produce his antityphoid serum. The serum which he employs is obtained from horses immunized by injections of the soluble typhoid toxin. This serum he uses in doses of from 10 to 12 c.c. at first, and if the temperature does not fall within a week, 4 or 5 c.c. more are injected. In connection with the serum he employs cold baths. In his reports he states that the average mortality in the other hospitals of Paris is 18 per cent., while in those under his charge among the patients treated by his serums and baths, the mortality is reduced to 4 per cent.

The manufacture of this serum is so difficult and the expense of obtaining it is so great, that it has not been extensively used in this country, and consequently American physicians are not prepared to express an opinion in regard to its use, or to administer it to patients.

Chantemesse maintains that the best results are obtained when the remedy is administered early, during the first week of the disease.

He reports that after the injection of his serum there is at first a period of reaction, when the temperature in some cases is elevated. This may last for from a few hours to several days. Subsequently, the temperature falls gradually, and the pulse is slowed, the blood-pressure raised, the quantity of urine increased, and the patient feels decidedly more comfortable. The temperature continues to fall for ten or twelve days, and the patient soon goes on to rapid convalescence. Should the patient seem to remain at a standstill, a second injection may be required.

GENERAL MANAGEMENT AND DIET

This subject was discussed in The Journal, Oct. 10, 1908, page 1233; Sept. 4, 1909, page 800; Oct. 15, 1910, page 1381.

THE PROTECTIVE TREATMENT OF THE HEART AND BLOOD-VESSELS DURING AND AFTER AN ATTACK

Everyone is familiar with the striking impression which typhoid infection makes on the heart during the course of the disease, and of the degenerative changes in the cardiac muscle which are found on post-mortem examination of that organ. It is not strange, in the case of a disease which lasts so long and which produces these degenerate changes in the heart, that during and following convalescence the heart should often be found to be profoundly affected.

The cardiac and vascular changes which are found after typhoid fever during the months and years following convalescence are of several kinds. It is well known that during the course of the disease pericarditis is a rare complication. Frequent cardiac murmurs are discovered during the later weeks of the disease. In many cases these disappear during convalescence, but if patients are examined from five to ten years after having experienced an attack of typhoid fever, it will be found that in the majority of these individuals the blood-pressure is considerably higher than in individuals of the same age who have not had typhoid fever. It will also be found that the radial arteries are palpable in a far larger proportion of persons who have had typhoid fever than in those who have not. Further, the average size of the heart is greater among those who have had typhoid fever than in those who have not. Finally, it will be found that a larger proportion of persons who have had typhoid fever will have organic disease of the heart than of those who have not suffered from an infectious disease.

It is maintained by many observers of wide experience that, with the exception of rheumatism, no infectious disease is more likely to produce permanent damage to the heart than typhoid fever.

Bearing these facts in mind, it is the obvious duty of the physician who takes care of a patient with typhoid fever, to guard against these different forms of damage to the cardiac and vascular system. It is the realization of these different forms of cardiovascular damage which gives added importance to the enforcement of rest during convalescence. This rest is recognized as being important for the patient not only in preventing a relapse, but it should also be recognized as being important in preventing the development of any of these circulatory troubles. The rest should be enforced for considerably longer than has commonly been done. This does not mean that the patient should be kept in bed for an indefinite number of weeks after convalescence has been established, but it means that he should be limited in the amount of exercise which he takes, and that he should not be allowed to undertake severe physical or mental work until several weeks have elapsed after the establishment of convalescence, and until careful examination fails to show any disturbance of the circulatory organs. Such disturbance may be indicated by a rapid pulse and weak action of the heart, and by various disturbances of the peripheral circulation such as coldness of the feet or sweating at night.

As undoubtedly the food taken by an individual affects the nutrition of the heart and its action, the diet recommended should be such as will not tend to produce arteriosclerosis or increase vascular tension. The amount of protein undoubtedly should be limited, although a moderate amount of protein is essential for the restoration of the degenerated tissues. Milk and fruit should for a long time constitute an important part of the diet.

The patient should be kept in bed until the pulse regains its normal rapidity, and the amount of exercise that he is allowed to take should not be such as will increase the action of the heart beyond the normal rate. It is also important that the nervous system should not be subjected to unusual irritation, and he should avoid cares and worries as far as possible. Protracted rest and a simple diet are the essential features of this protective treatment.

NERVOUS, MENTAL AND SPINAL CONDITIONS

Perhaps one of the most striking results of the progress which has been made during the last few decades in the treatment of typhoid, is the diminution of the frequency and severity of the nervous phenomena observed during the course of the disease. The so-called typhoid condition characterized by a dry and brown coated tongue, lips and teeth covered with sordes, dull and apathetic mind, or delirium, sometimes violent and sometimes busy, with muttering, muscular tremors, and subsultus tendinum, are comparatively rarely seen at the present day. Now other nervous phenomena are demanding attention, and among these may be mentioned changes in the mental condition both before and after the attack of the fever. Cases have been reported, chiefly in patients who had a defective mental inheritance or who themselves were not up to the average of mental development, in which the attack of typhoid fever has been preceded by maniacal delirium, which subsided with the onset of the fever. More frequently, but yet only occasionally, during convalescence various disturbances of the mind have been observed which are classed together as the psychoses of typhoid fever. In the initial delirium, motor excitement appears to be a constant feature, so that when an unexplainable attack of mania, accompanied by this motor excitement, occurs, it is well, if the patient is found to have any fever, to test his blood by the Widal method.

During convalescence, the common forms are the so-called collapse delirium, in which the patient imagines that he has been taken from his previous surroundings, that he is somewhere other than in the place where he really is, or there may be various forms of mania or melancholia. In addition to these, various forms of neurasthenic phenomena are frequently observed.

With a view to avoiding and preventing these postfebrile phenomena, the nervous system should be carefully watched during the course of the disease and such measures adopted as will quiet nervous restlessness and prevent loss of sleep. The most important of these methods is cold or tepid sponging, or other cold applications. When for any reason these are impracticable or ineffective, they may be supplemented by hypnotic drugs, such as the bromid of sodium, chloral, sulphonethylmethane (trional), or morphin. The last in small dose is often the best.

As soon as convalescence is fairly established, the nutrition should be rapidly improved by the addition of such food as the patient can digest and assimilate. The patient should maintain a condition of rest so long as there is any evidence of irritability or nervous instability. He should not be disturbed by visitors or by having business cares and worries brought to his attention.

The prognosis of these conditions and even of a mild insanity is, as a rule, favorable, and treatment at home may be continued for a greater length of time than in cases of ordinary insanity.

In connection with these nervous and mental disorders may be mentioned the condition described by Gibney as typhoid spine, which consists of an inflammation of the structures in and around the joint called by him perispondylitis. This condition is characterized by a great deal of pain in the spine, usually in the lumbar region, accompanied by swelling and tenderness of the boney structure of the affected region. It should be distinguished from a painful condition of the muscles on each side of the spine resulting from strain from the patient lying with his back not properly supported (often too soft bed-springs), also from the hypersensitive spine seen in neurasthenic patients and other functional troubles. The pain is sharp and shooting, relieved by lying flat on the back, but aggravated by any movement of the spine. The treatment consists of rest in bed, with counterirritation and massage. The patients as a rule recover.

THE HAIR IN TYPHOID FEVER

Typhoid fever in all the aspects of its symptomatology, pathology and treatment has been so voluminously discussed by so many teachers and writers that it is surprising to find in the literature relating to this disease so little definite information in regard to the occurrence of loss of hair and its prevention. In works treating of dermatology this matter is incidentally mentioned under the head of *alopecia prematura* or *presenilis*. To the condition here to be discussed the term *defluvium capillorum* is also applied.

Naturally, during the height of the fever when the physician is exercised in attempting to prevent the death of the patient, to relieve the fever, to maintain the circulation, and to keep up the general nutrition, it is not strange that a matter of so little life and death importance as the hair should be neglected; but after the fever has left the patient, after convalescence has become established, and when the patient walks around and receives the visits of friends, one of the most annoying symptoms in a large number of cases is the impending and active loss of the hair. This causes great annoyance, especially to female patients, and its causation and prevention are worthy of careful study by the physician.

The condition is undoubtedly associated with the defective nutrition of the entire body, and one of the most important measures for combating it is by improving the general nutrition. Of course, food stands in the first place in this regard, but it may be supplemented by medicinal treatment, and especially by the addition of moderate sized doses of arsenic, which is generally recognized as having a direct action on the nutrition of the skin, perhaps four or five drops of Fowler's solution, well diluted, three times a day, after eating. Calcium glycerophosphate is also of value.

Locally, the nutrition of the skin may be improved by massage with the application of a moderate amount of some oily substance, of which the best perhaps is the official adeps lanæ hydrosus. In addition, such remedies as stimulate the scalp are of considerable importance. Among the different preparations recommended for stimulation of the scalp are various solutions containing tincture of cantharides, various cinchona or quinin preparations, sulphur either suspended in solution or in various strength of ointments, oil of turpentine combined with bland oils, or with alcohol; and solutions containing ammonia or chloroform.

When the hair commences to fall out after an attack of typhoid fever, the question of cutting the hair or shaving the scalp is frequently raised. It is, of course, of great importance, especially if the patient is a woman, to retain the hair if possible. Certainly, no physician should advise cutting off the hair when it is luxuriant, and before advising it the local applications already enumerated should be tried. In severe cases, in which these measures are not successful, it unquestionably is beneficial to cut the hair. In the majority of cases this will stop the falling of the hair, and ultimately, new hair will grow, and the new growth will be of equal thickness with the original. Occasionally, perhaps, it may be slightly coarser.

THE LOS ANGELES SESSION

THE SIXTY-SECOND ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION TO BE HELD AT LOS ANGELES, JUNE 27-30, 1911

OFFICIAL CALL

TO THE OFFICERS AND MEMBERS OF THE CONSTITUENT ASSOCIATIONS OF THE AMERICAN MEDICAL ASSOCIATION

The sixty-second annual session of the American Medical Association will be held on Tuesday, Wednesday, Thursday and Friday, June 27, 28, 29 and 30, 1911, at Los Angeles, Cal

The House of Delegates will convene at 10 a. m., Monday, June 26, 1911.

REPRESENTATION

In accordance with the reapportionment of delegates made at the Atlantic City Session of 1909, state associations are entitled to delegates for 1911-12 as follows:

Alabama	3	Louisiana	2	Oklahoma	2
Arizona	1	Maine	1	Oregon	1
Arkansas	2	Maryland	2	Pennsylvania	9
California	3	Massachusetts	6	Philippine Is.	1
Colorado	2	Michigan	3	Rhode Island	1
Connecticut	2	Minnesota	2	South Carolina	2
Delaware	1	Mississippi	2	South Dakota	1
Dist. Columbia	1	Missouri	5	Tennessee	3
Florida	1	Montana	1	Texas	5
Georgia	2	Nebraska	2	Utah	1
Hawaii	1	Nevada	1	Vermont	1
Idaho	1	New Hampshire	1	Virginia	3
Illinois	9	New Jersey	3	Washington	2
Indiana	4	New Mexico	1	W. Virginia	2
Iowa	3	New York	11	Wisconsin	3
Canal Zone	1	North Carolina	2	Wyoming	1
Kansas	2	North Dakota	1		
Kentucky	4	Ohio	7		

The twelve sections of the American Medical Association, the Medical Department of the Army, the Medical Corps of the Navy and the Public Health and Marine-Hospital Service are entitled to one delegate each.

EXTRACTS FROM BY-LAWS

The following quotations from the By-Laws of the American Medical Association are given in this connection, for their bearing on the qualifications of delegates, their election and their time of service.

> "No one shall serve as a member of the House of Delegates who has not been a member of the American Medical Association for at least two years."
>
> "Delegates and alternates from constituent associations shall be elected for two years. Constituent associations entitled to more than one representative shall elect them so that one-half, as near as may be, shall be elected each year. Delegates and alternates elected by the sections, or delegates appointed from the United States Army, United States Navy and United States Public Health and Marine-Hospital Service, shall hold office for one year."—Chap. III, Secs. 1 and 2, By-Laws.

GENERAL MEETING

The General Meeting which constitutes the opening exercises of the scientific functions of the Association will be held at 10:30 a. m., Tuesday, June 27, 1911.

REGISTRATION DEPARTMENT

The Registration Department will be open from 8:30 a. m. until 5:30 p. m. on Monday, Tuesday, Wednesday and Thursday, June 26, 27, 28 and 29, and from 9 to 10 a. m. on Friday, June 30, 1911.

William H. Welch, Baltimore, President.
George H. Simmons, Chicago, Secretary.

LOS ANGELES

MEETING PLACE OF THE SIXTY-SECOND ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION

Only three times in the past has the American Medical Association held its meeting on the Pacific slope, the past meeting places having been San Francisco in 1871, Portland in 1905 and San Francisco in 1894. This will be the first time that a session has been held in Los Angeles.

For the better information of those who anticipate being present at the Sixty-Second Session of the Association, a description * of the city and its attractions, the surrounding points, coast resorts, etc., will be of interest.

Los Angeles, the City of the Angels

There are few cities in the United States that have had such a remarkable and varied career as Los Angeles, the chief city of southern California, and the commercial metropolis of the southwest section of the United States. Few cities of this size, moreover, are so well known throughout the length and breadth of this country, as well as abroad. The rapid growth of Los Angeles, from an insignificant semi-Mexican town to a metropolitan city, has been told and retold, until it is familiar in a general way to millions of Americans, while the attractions offered by the city to health-seekers, pleasure-seekers and tourists have been spread abroad by hundreds of thousands of visitors who, after one trip to this section, are usually anxious to return, frequently becoming permanent residents.

Population

During the past thirty years Los Angeles has grown from population of 11,000 in 1880, to 319,198 by the census of 1910. There are three leading features that have contributed to such growth. These are climate, soil and location. Any one of these advantages would be sufficient to build up a large city, but taken together they insure the future of Los Angeles as the metropolis of the southwest.

Name and Origin

The original name of the pueblo or town of Los Angeles, following the custom that then prevailed among the Latin races of giving religious names to places, was Nuestra Senora de Los Angeles, sometimes written Nuestra Senora la Reina de Los Angeles—Our Lady, the Queen of the Angels. This has been shortened by the practical Yankees to Los Angeles. Los Angeles was founded on Sept. 4, 1781, by a small band of forty pablodores or colonists, who had been recruited in the Mexican states of Sinaloa and Sonora, and brought here under command of a government officer, to found an agricultural colony, for the purpose of raising produce for the soldiers at the presidios. The first census of the little city, taken in August, 1790, gave the total population as 141. They were a mixed class, composed of one European, seventy-two Spanish-Americans, seven Indians, twenty-two mulattoes and thirty-nine Mestizos. As recently as 1831, fifty years after the founding of the pueblo, the population was only 770. In January, 1847, the population was 1,500. It began to grow rapidly about 1880, and has continued until it has reached the figures quoted above.

---

* Information for this article was furnished by George H. Kress, M.D., secretary-general of the Los Angeles Committee of Arrangements.

Streets

Considering that twenty years ago it had not a single paved street, Los Angeles has made remarkable progress in street improvements. There are now over 450 miles of graded and graveled streets, 63 miles of paved streets and 320 miles of sewer. Los Angeles has a complete sewer system, including an outfall sewer to the ocean.

Lighting

At night Los Angeles presents a brilliant appearance. It was the first city in the United States entirely to abandon gas for street lighting, and to replace it by electricity, which was done twenty-five years ago, and it is now one of the best lighted cities in the Union. Many of the lamps are on high masts. Seen from one of the surrounding hills, the view of the city at night is most beautiful and striking. Broadway and Spring streets are now lighted their entire length by clusters of electric lights on handsome iron electroliers, 100 feet apart, paid for by the property owners, the city supplying the "juice." A similar lighting scheme has been installed on Main Street to Tenth, a distance of ten blocks, and also on Hill Street to Pico, a distance of thirteen blocks.

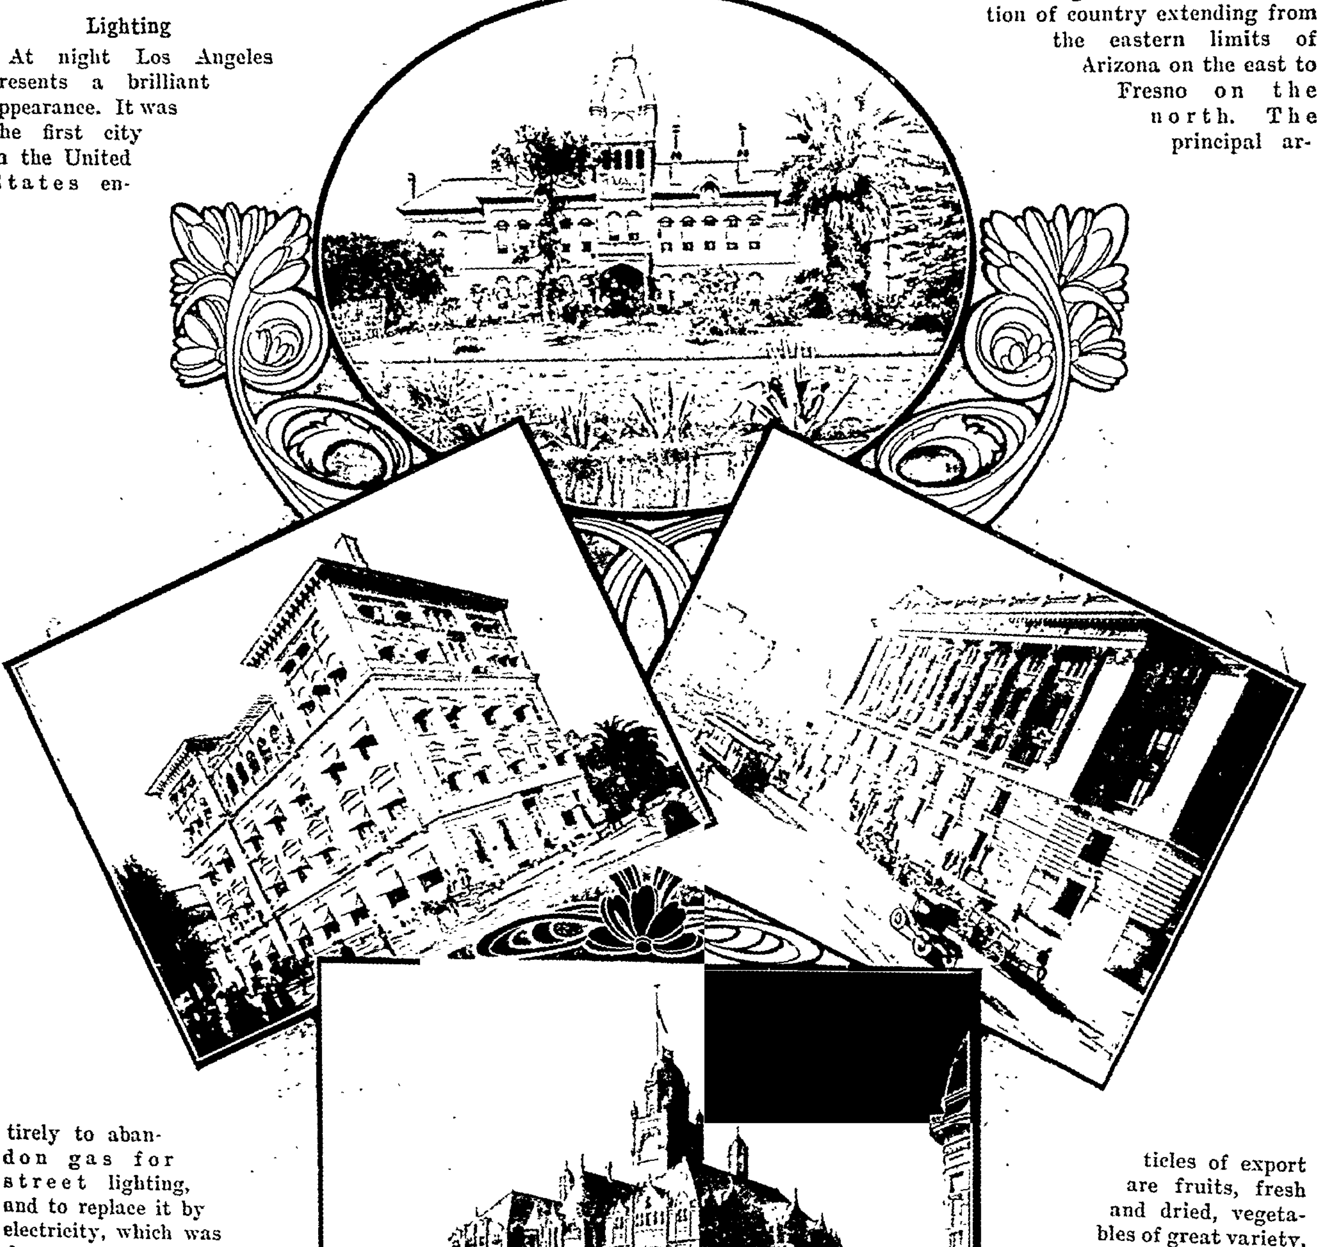

Fig. 1.—Public buildings in Los Angeles: State Normal School at the top, the Postoffice at the right, the California Club at the left, and the Court House at the bottom.

Business

That Los Angeles is and will always remain the commercial metropolis of southern California admits of no doubt. The city possesses the great natural advantage of being located on the shortest route, by the easiest grades, between the Pacific and the Atlantic oceans. The merchants of Los Angeles do a large business with a section of country extending from the eastern limits of Arizona on the east to Fresno on the north. The principal articles of export are fruits, fresh and dried, vegetables of great variety, beans, wine and brandy, wool, honey, canned goods, sugar, olives, corn, wheat, barley, petroleum and by-products.

The assessed valuation of property in the city this year, including personal property, is $265,570,272.

Banks

The banks of Los Angeles are noted throughout the country for their solid and prosperous condition, with deposits aggregating $102,000,000. The clearings of the Los Angeles city banks for the year 1908 amounted to $505,588,756. Los Angeles has been leading all cities in the United States in increase of bank clearings.

Railroads

Los Angeles possesses the advantage of four transcontinental lines. These are the "Sunset Route" of the Southern Pacific, by way of El Paso and New Orleans, the Ogden route of the same company, connecting with the Central and Union Pacific, the Sante Fe route, by way of Albuquerque, and the San Pedro, Los Angeles and Salt Lake Railroad, the operation of which began May 1, 1905, opening up a comparatively unknown section in southern Utah and Nevada, which is wonderfully rich in precious and useful minerals. The Southern Pacific has two lines between Los Angeles and San Francisco—one through the San Joaquin Valley and the other along the coast. The Santa Fe also connects with San Francisco via Barstow, in San Bernardino County. Altogether, there are over a dozen lines of railway centering in Los Angeles. The Pacific Coast Steamship Company runs vessels regularly from Los Angeles County ports to San Francisco on the north and San Diego on the south.

Harbor

Reference is made elsewhere to the work of the national government on a deep-water harbor at San Pedro. This work, when completed, will give a great impetus to foreign commerce, and Los Angeles should before long become an important point for Oriental trade.

When the Isthmian canal is constructed the coast of Los Angeles County will be on the direct course of steamships sailing from the Atlantic coast and from European to Asiatic ports. It will also furnish a greatly enlarged market for the horticultural products of this section.

Street Railways

The street railway system of Los Angeles is excellent. There is probably no city of the size in the United States that has a more modern or a better equipped system. The total mileage of single track is over 300 miles, all electric. There are suburban electric lines to the ocean beach towns, Santa Monica, by two different routes; to Redondo, also by two routes; to Port Los Angeles, Long Beach, Newport, Huntington Beach, Naples and San Pedro, and to inland towns, Pasadena and Altadena, Alhambra, San Gabriel and Monrovia, Whittier, Azusa, Glendora, Sierra Madre, Covina, La Habra, Glendale and Santa Ana in the fruit country. The suburban electric railroads radiating from Los Angeles aggregate 767 miles of single track. They are almost all double track. Some have four tracks.

Building

For a dozen years past Los Angeles has been the scene of great activity in building operations. Scores of fine business blocks and hundreds of handsome residences have been built. The value of the building permits issued in Los Angeles during the year 1908 amounted to $10,000,000. The actual value of the buildings was much larger.

Parks

There are a dozen public parks within the city limits, aggregating over 600 acres, of which six are of considerable size. Westlake Park, 35 acres in area, on the Seventh Street car line, is one of the most popular open-air resorts, and is in the heart of a splendid residence section. It has a lake with boats, fine drives and extensive views from the adjacent hills. Eastlake Park, in East Los Angeles, covers 50 acres, and has been made attractive. Here also is a lake and the park nurseries and a menagerie. Prospect Park on Boyle Heights is a small but beautiful place, with many choice trees and shrubs. The oldest and best improved of the city parks, on Sixth Street, not far from the business center, is known as Central Park. The trees have attained a large growth. Hollenbeck Park is a tract of about 20 acres, on the east side of the river, on Boyle Heights. It has been improved with shade trees and a small lake. Echo Park, a beautifully improved tract in the northwestern part of the city, contains the largest body of water in Los Angeles.

Elysian Park, 500 acres in area, is a remnant of the thousands of acres of such land which the city formerly owned. It may safely be said that this tract offers the greatest possibilities for diversity of growths of any piece of ground within the limits of an American municipality. Much of the land is within the frostless belt. The views of mountains, valley and ocean, city and plain are grand in the extreme.

What has been said in regard to Elysian Park is true of Griffith Park, a tract of 3,000 acres, donated to the city. It is located about a mile north of the city limits, and embraces a varied assortment of mountain, foothill and valley scenery. A boulevard to connect the parks of Los Angeles has been commenced. The large tract of land in the southwest part of city, known as Exposition Park, was recently made part of Los Angeles. Plans have been prepared to make this a handsome and attractive park. A museum, an armory and a mammoth exposition hall are being erected.

Los Angeles has now seven regular public playgrounds and four vacation or summer centers. The cost of maintaining the playgrounds during the past year was $42,000. The public library maintains a branch at three of the regular playgrounds. During the winter months a series of free lectures and entertainments is given.

Homes

After all is said, the chief attraction of Los Angeles to new arrivals lies in its beautiful homes. The rare beauty of the grounds surrounding the attractive homes of Los Angeles, Pasadena and other Los Angeles County cities is a constant theme of admiration on the part of eastern visitors. Other cities may show greater business blocks, but when it comes to gardens, Los Angeles is *facile princeps*. The mildness of the climate permits the most delicate plants and trees to flourish in the open air all through the winter.

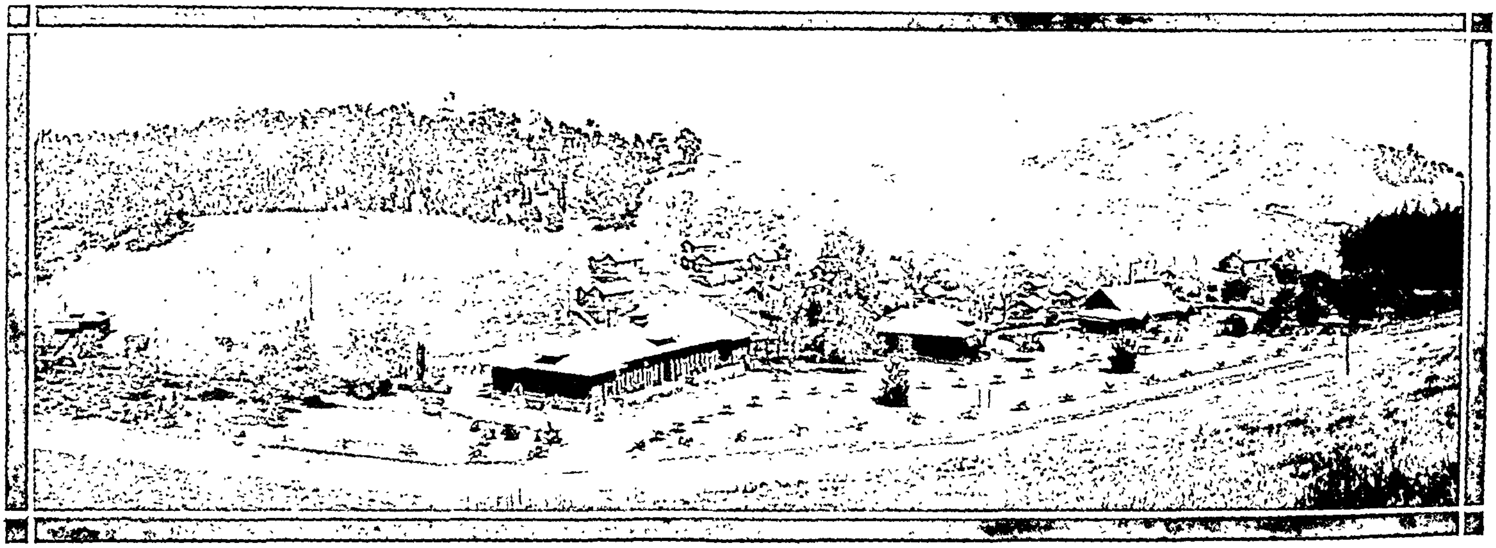

Fig. 2.—View of the Barlow Sanatorium for the Poor Tuberculous of the County of Los Angeles.

A great variety of architecture is found among the residences of Los Angeles. The picturesque and comfortable early mission style, which should have been more extensively adopted long ago by the American settlers, is at length coming into vogue. Some of the more pretentious of these mission residences have spacious tiled courtyards, covered with glass, in which fountains splash, flowers bloom and birds warble.

Another comfortable and artistic style of residence that has become exceedingly popular during the past few years is the bungalow, adapted from India—a cottage of one or one and one-half stories, with from three to seven rooms, built of lumber and shingled, with wide eaves.

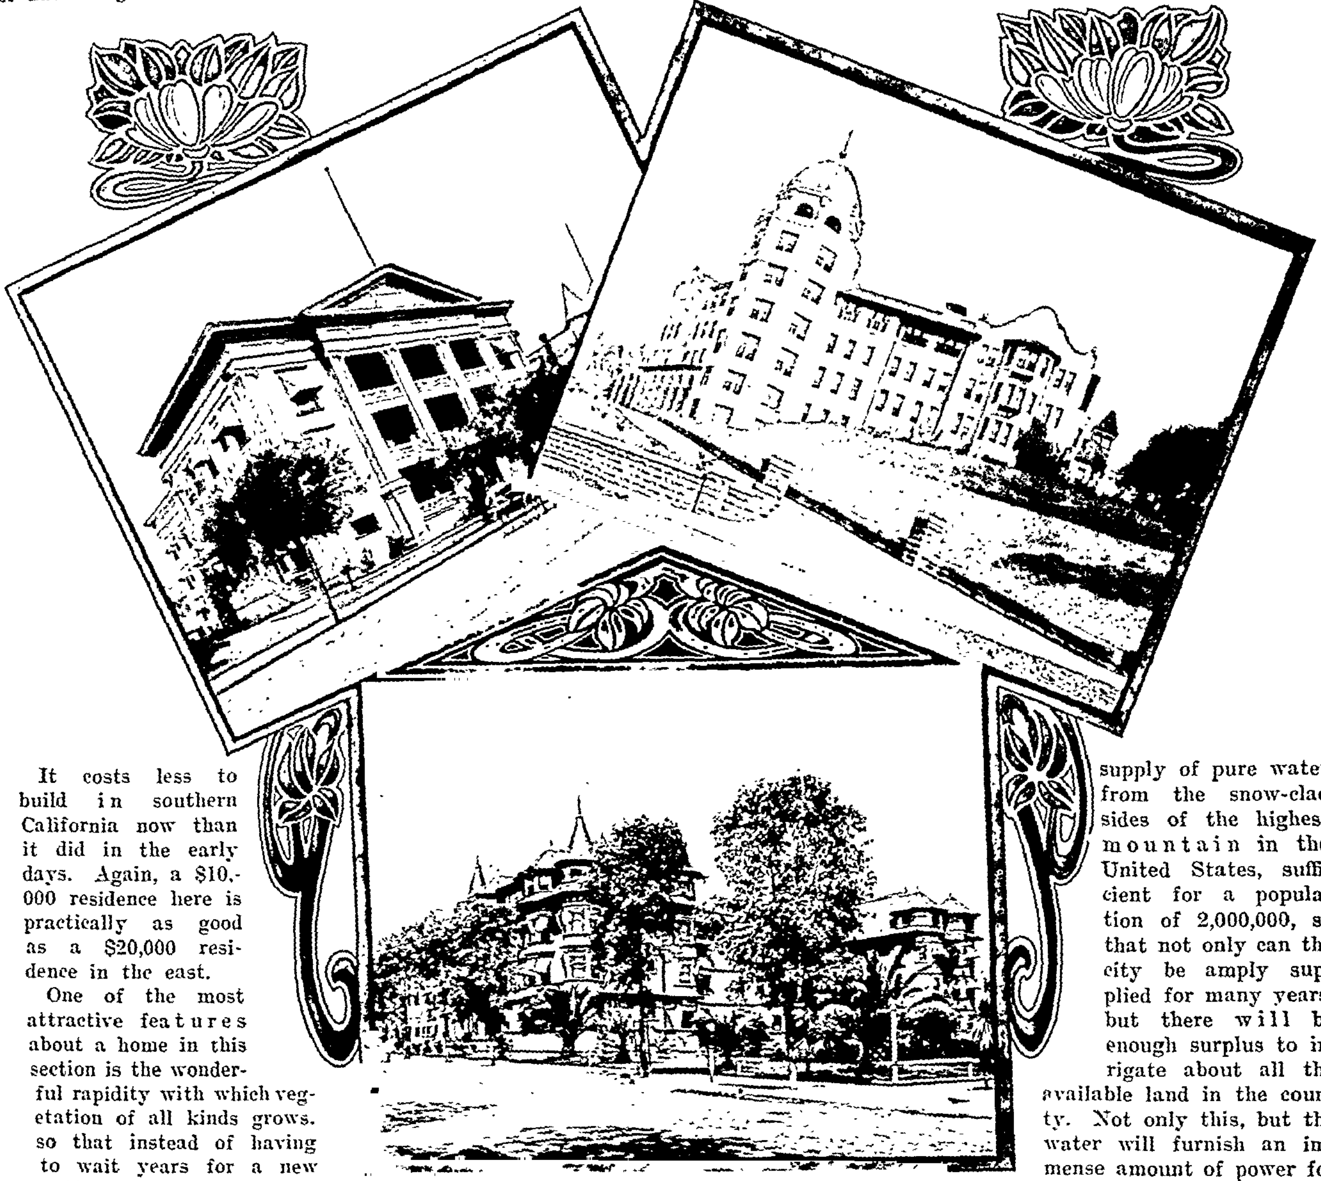

Fig. 3.—A group of Los Angeles hospitals: Pacific Hospital above to the left, the Sisters' Hospital at the right, and the California Hospital below.

It costs less to build in southern California now than it did in the early days. Again, a $10,000 residence here is practically as good as a $20,000 residence in the east.

One of the most attractive features about a home in this section is the wonderful rapidity with which vegetation of all kinds grows, so that instead of having to wait years for a new residence to assume a settled and homelike appearance, the owner has to wait only a few months until his house is surrounded with thrifty plants and climbing vines, while even some trees, such as the eucalyptus, grow to a respectable size within a year, and can be planted around the lot while less rapidly growing trees are attaining size, thus obviating the bare hard appearance attaching to new residences in less favored climates, however beautiful architecturally the building may be.

A Cosmopolitan Place

The population of Los Angeles is cosmopolitan. During the past twenty years it has received accessions to its population from every state in the Union and from almost every country in the world. For instance, a statement published in the Los Angeles *Times* showed that, a few years ago, of the 53,413 voters then on the register of Los Angeles County, only 5,244, or less than 10 per cent., were natives of California.

Water-Supply

The most notable thing that has ever happened to the city of Los Angeles is the acquirement by the city of water rights, extending for many miles along the banks of the Owens River, in Inyo County. This water will be brought to the city a distance of 220 miles, by means of an aqueduct and more than 20 miles of tunnels. Work is now rapidly progressing and will be completed in 1912. This will give Los Angeles a supply of pure water from the snow-clad sides of the highest mountain in the United States, sufficient for a population of 2,000,000, so that not only can the city be amply supplied for many years, but there will be enough surplus to irrigate about all the available land in the county. Not only this, but the water will furnish an immense amount of power for electric lighting and for power for factories. The cost of this great enterprise is estimated at $25,000,000. The bonds were carried by a vote of ten to one.

Climate

Decidedly the chief attraction of southern California is its climate. This is the feature that brings three-fourths of the eastern visitors to southern California.

Southern California—that is, the section we have indicated, especially including Los Angeles—has an "all-the-year-round" climate. This is a rare and inestimable feature, possessed by very few sections of the world. It is well to insist specially on this point, because very erroneous ideas prevail on the subject in the east, where it is generally believed, among those who have not spent an entire year with us, that the whole of California is a counterpart of hades during the summer—a veritable fiery furnace, as its name would indicate. Strangers have yet to learn that California *includes* within its limits almost as great a variety of climates as may be found in the world. Take, for instance, an August afternoon in San Francisco and at Indio in the Colorado desert. In the former place the inhabitants will be found attired in heavy overcoats and sealskin wraps, or seated around large open coal fires; at the latter a thin shirt and overalls are too warm for comfort. Los Angeles occupies a happy position between these two extremes, and our climate is shared, with slight variations, by the suburbs for 20 miles around, becoming somewhat moister and cooler toward the ocean, dryer and warmer toward the mountains.

The winter season is marked by the rains, which come between November and April. This is really the spring, when the grass and flowers mantle the hills. Usually the rain storms do not last more than two or three days at a time, with frequent spells of fine weather lasting ten days or more. The rainfall at Los Angeles for the past twenty-five years averaged about 16 inches, the lowest being 5.53 and the highest 38.13. Thunderstorms are very rarely experienced and cyclones are unknown. During the year an average of 316 days will be found with cloudless skies or when the sun is but partly obscured.

For a few days in summer the mercury rises high in Los Angeles, yet, owing to the dryness of the atmosphere, 100 degrees of heat is less oppressive than 80 degrees in New York. The cool trade wind from the Pacific is felt nearly all summer, and is the great modifier of the heat, rendering the hottest day bearable. In winter the modifying influences of a warm return current from the south are enjoyed, which, south of Point Conception, takes the place of the Pacific Gulf stream, the Japanese current Kuro-Shiwo, which sweeps down the Pacific Coast. This explains why the water at Santa Monica has a temperature of 61 degrees in January, while that of Newport on the Atlantic at the same time is 32 degrees.

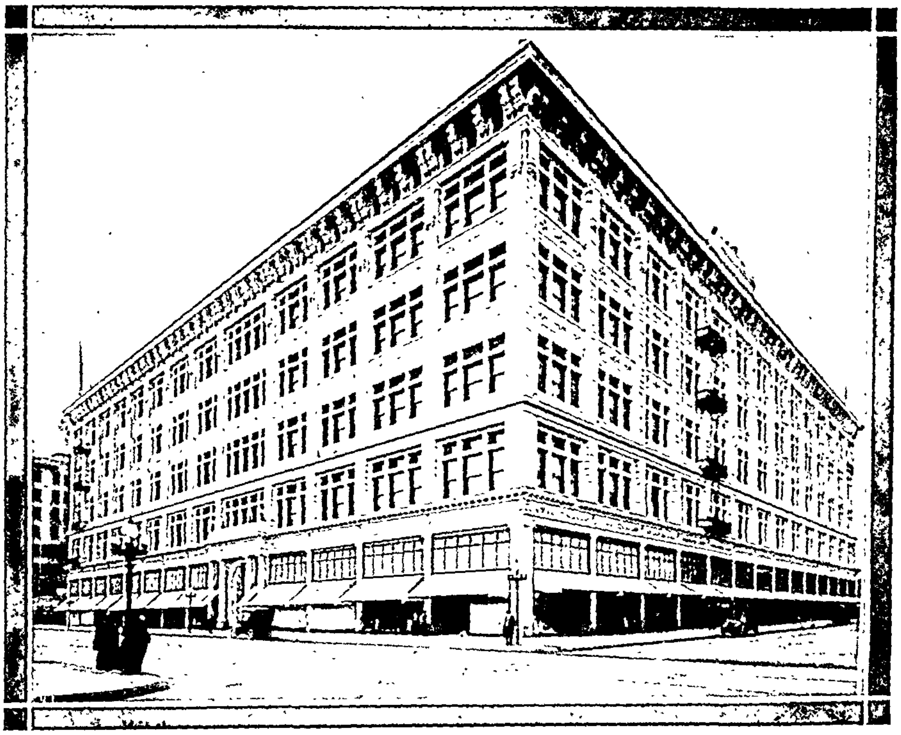

Fig. 4.—The Hamburger Building, Eighth and Broadway, where will be found the Registration Bureau, Post Office, Telegraph Office, Scientific Exhibit, Commercial Exhibit, and also the roof garden, where the general smoker will be given.

Facts About Los Angeles

Center of great oil-producing fields, as it also is of the great orange belt.

City will spend $10,000,000 on San Pedro harbor, already one of the best on the Pacific Coast.

Wholesale trade with the southwest, including Mexico, exceeds $300,000,000 a year and growing rapidly.

Shopping district compares favorably with any in the large eastern cities.

Local general colleges are the University of Southern California, Occidental College, Throop Polytechnic Institute (Pasadena), Pomona College (Pomona), and University of Redlands (Redlands).

Local medical colleges are two: the State University Medical Department (Los Angeles Branch), which gives instruction in the last two years only, the first two years' instruction being given at Berkeley; and the College of Physicians and Surgeons of the University of Southern California, which gives the regular four years' course.

Churches, all denominations, 225; public schools, 117; teachers employed, 1,440; school children census, 53,954; enrolment, 50,000; miscellaneous private schools and colleges, 40.

Public library contains 137,184 volumes, home circulation, 773,572. In addition, there are other libraries in the city with total of 103,643 volumes.

A resort both winter and summer, and one of the busiest and most enterprising cities in the United States, as it also is one of the most beautiful.

A dozen resorts on the Pacific Ocean may be reached within forty minutes by trolley and steam lines.

There are more than sixty cities and towns within two hours' ride of Los Angeles, having populations ranging from 500 to 40,000.

Short Trips from Los Angeles

The following comprise only a few of the trips that may be made from Los Angeles in a couple of days or less:

HALF-DAY TRIPS

Santa Monica, Ocean Park, Venice.

Terminal Island, Long Beach, San Pedro.

Redondo Beach, Hermosa, Manhattan, Playa del Rey.

Baldwin's Ranch, San Gabriel Mission.

Ostrich Farm, Soldiers' Home, Pasadena, Whittier, Hollywood and Cahuenga Valley.

Observation Car over the Los Angeles Railway.

ONE-DAY TRIPS

Mount Lowe; electric road and cable incline.

"Kite-Shaped Track" of the Santa Fe System, including stops at Riverside and Redlands.

"Inside Track" of the Southern Pacific, including stops at Pomona, Ontario, Redlands and Riverside.

"Orange Grove Trips" of the Salt Lake Route, with stop at Riverside and by trolley to Redlands.

"Balloon" trip of the Los Angeles-Pacific.

Tilton's Trolley Trip, Pacific Electric.

"Surf" trip of the Pacific Electric Railway.

Santa Ana, Orange, Tustin and surroundings.

Oil wells of Whittier, Fullerton and Puente.

Monrovia, Duarte, Azusa and Glendora (heart of San Gabriel Valley).

San Buenaventura, San Juan Capistrano Mission.

Santa Catalina Island, Santa Barbara.

TWO-DAY TRIPS

Wilson's Peak; railroad, electric, stage and burros; Elsinore.

San Luis Rey Mission; railroad and stage.

San Diego, Coronado Beach and Mexican line.

San Diego may be reached by railroad or by the Pacific Coast steamship line, by large, modern boats, sailing three times a week from San Francisco, and touching at Los Angeles Harbor. The distance is 120 miles and takes about seven hours.

THE SCIENTIFIC PROCEEDINGS

The Papers to Be Read at Los Angeles—The Preliminary Program and the Official Program

The following is a partial list of titles of papers to be read before the various sections. The order here is not necessarily the order which will be followed in the Official Program. This Official Program will be a pamphlet similar to those issued in the previous years, and will contain the final program of each section, with abstracts of the papers, lists of committees, programs of the General Meeting and of the meetings of the House of Delegates, lists of entertainments, map of Los Angeles, etc. To prevent misunderstandings and to protect the interests of advertisers, etc., it is here announced that this Official Program will contain no advertisements. It is copyrighted by the American Medical Association and will not be distributed before the session. A copy will be given to each member on registration.

SECTION ON PRACTICE OF MEDICINE

Chairman, Allen A. Jones, Buffalo, N. Y.; Secretary, Wilder Tileston, New Haven, Conn.

Clinical Phases of Arteriosclerosis (15 minutes). Thomas D. Coleman, Augusta, Ga.

Verruca Peruana or Carrion's Disease (15 minutes). H. A. Giltner, U. S. Navy.

Epidemiology of Pneumonia (10 minutes). C. M. Richter, San Francisco.

Successful Treatment of a Typhoid Bacillus-Carrier by Vaccination (10 minutes). Walter Brem and F. C. Watson, Cristobal, Canal Zone.

Causation and Treatment of Fever in Tuberculosis (10 minutes). F. M. Pottenger, Monrovia, Cal.

Streptothrix (Actinomycosis) of the Lungs (15 minutes). Norman Bridge, Los Angeles.

Hemorrhagic Erosions of the Stomach (10 minutes). N. W. Jones, Portland, Ore.

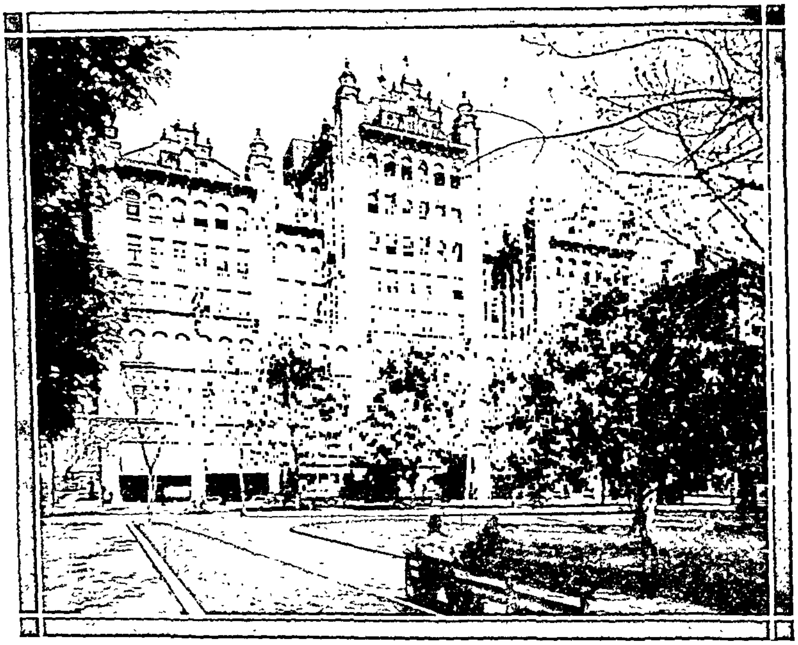

Fig. 5.—The Baptist Temple and Auditorium, Fifth and Olive Streets, where the general meeting will be held. Here also are halls for the meetings of the Section on Surgery, Section on Obstetrics and Diseases of Women, and Section on Preventive Medicine and Public Health.

Immuno-Diagnostics in Internal Medicine (15 minutes). W. J. Butler, Chicago.

The Leukocytology of Typhoid and Paratyphoid Fevers (10 minutes). J. F. Hultgen, Chicago.

Effects on Secondary Anemia by Hypodermic Injections (10 minutes). W. Jarvis Barlow, Los Angeles.

Reserve Renal Capacity in Chronic Interstitial Nephritis (10 minutes). Edward F. Wells, Chicago.

Pathologic Findings in Hypertension (10 minutes). Roger I. Lee, Boston.

Myatonia Congenita (Oppenheim); Report of a Case with Autopsy (15 minutes). W. T. Councilman and C. H. Dunn, Boston.

New Clinical Values in the Treatment of the Gastric Neuroses (15 minutes). Charles L. Greene, St. Paul, Minn.

Infantilism with Disease of the Pituitary Gland (15 minutes). A. W. Hewlett, Ann Arbor, Mich.

Importance of Quantitative Regulation of Diet (15 minutes). H. D. Arnold and R. C. Larrabee, Boston.

Pleurisy and Empyema in Pneumonia (10 minutes). J. M. Anders, Philadelphia.

Value of So-Called Digestants in Preparation of Materials to be Examined for Acid-Fast Organisms (particularly Tubercle Bacilli), with Clinical Results of Two Years' Study of "Antiformin" (10 minutes). Frank Smithies, Ann Arbor, Mich.

Experimental and Clinical Studies of a Modified Vaccine Treatment of Pneumococcus Infections in Animals and Man (20 minutes). S. P. Beebe, New York, and P. K. Brown, San Francisco.

SYMPOSIUM ON SYPHILIS

Laboratory Diagnosis of Syphilis (15 minutes). L. S. Schmitt, San Francisco.

Visceral Syphilis (20 minutes). Frank Billings, Chicago.

Value of the Wassermann Reaction and of Salvarsan (15 minutes). Albert Keidel, Batimore.

Disadvantages Incident to the Administration of Salvarsan (10 minutes). D. W. Montgomery, San Francisco.

Adequate Treatment of Syphilis (15 minutes). W. T. Wootton, Hot Springs, Ark.

Salvarsan (10 minutes). E. G. Ballenger, Atlanta, Ga.

Treatment of Diabetes (15 minutes). A. J. Hodgson, Waukesha, Wis.

Early Diagnosis of Hyperthyroidism (15 minutes). John A. Witherspoon, Nashville, Tenn.

Bubonic Plague with Special Reference to that of Ground Squirrel Origin (15 minutes). G. W. McCoy, San Francisco

Treatment of Intestinal Amebiasis (15 minutes). W. E. Musgrave, Manila, Philippine Islands.

Experimental Work on Intestinal Auto-Intoxication (20 minutes). J. W. D. Maury, Rochester, Minn.

Some Obscure Conditions of the Digestive Tract as Studied by the Roentgen Ray (20 minutes). G. R. Satterlee and L. T. LeWald, New York.

Availability of Roentgen Rays in the Clinical Study of the Pancreas (10 minutes). A. W. Crane, Kalamazoo, Mich.

Oration in Medicine: A Clinical Study of Disturbances in Rate and Rhythm of Respiration. C. F. Hoover, Cleveland, Ohio.

Relation of the Symptomatology and Pathology to Operative Mortality in Exophthalmic Goiter (10 minutes). H. S. Plummer, Rochester, Minn.

Mobility of the Heart. Dudley Fulton, Los Angeles.

SYMPOSIUM ON POLIOMYELITIS

Joint Meeting With the Section on Diseases of Children

Epidemiologic and Etiologic Studies of Acute Poliomyelitis in Pennsylvania (20 minutes). Samuel G. Dixon, Harrisburg, Pa., and H. T. Karsner, Philadelphia.

Recent History and Etiology of Infantile Paralysis (20 minutes). R. W. Lovett and M. W. Richardson, Boston.

Pathology, Symptomatology, Diagnosis, Prognosis, Prophylaxis and Treatment of Infantile Paralysis (20 minutes). R. W. Lovett and M. W. Richardson, Boston.

Infantile Paralysis as Observed in Massachusetts, 1907-1910 (20 minutes). R. W. Lovett and M. W. Richardson, Boston.

SECTION ON OBSTETRICS AND DISEASES OF WOMEN

Chairman, H. G. Wetherill, Denver; Secretary, C. Jeff Miller, New Orleans

Chairman's Address: Retrospection and Introspection: Our Opportunities and Obligations. H. G. Wetherill, Denver.

Carcinoma of the Clitoris and Report of Case.
Charles D. Lockwood, Pasadena, Cal.

Torsion of a Subserous Pedunculated Fibroid Complicating Pregnancy at Four and One-Half Months. Operation; Recovery with Delivery at Term.
E. M. Lazard, Los Angeles.

Adiposity of the Mammary Glands.
J. R. Guthrie, Dubuque, Iowa, and Henry Albert, Iowa City, Iowa.

The Exciting Causes, Means of Prevention and Early Treatment of Cancer of the Uterus.
A. E. Benjamin, Minneapolis.

Hemorrhagic Degeneration in Myomas.
Arthur E. Hertzler, Kansas City, Mo.

Introduction and Development of Antiseptic Surgery in America.
Henry O. Marcy, Boston.

Parametritis Posterior and its Associated Reflex Disturbances.
Fred J. Taussig, St. Louis.

Prevention of Postoperative Gynecologic Psychoses.
H. P. Cole, Mobile, Ala.

Value of Pyelography.
W. F. Braasch, Rochester, Minn.

Postoperative Urinary Retention and Cystitis.
J. H. Jacobson and J. G. Keller, Toledo, O.

Pericystitis.
M. L. Harris, Chicago.

Removal of Ureteral Calculi by Cystoscopic Methods.
Bransford Lewis, St. Louis.

Pathologic Kinks and Adhesions in the Terminal Portion of the Ileum.
Franklin H. Martin, Chicago.

Treatment of 140 Consecutive Cases of Uterine Myoma
Walter B. Dorsett, St. Louis.

Surgical Treatment of Ptosis of Abdominal Organs by Hammock Operation.
R. C. Coffey, Portland, Ore.

Essential Points in Round-Ligament Surgery.
Channing W. Barrett, Chicago.

Use of the Pessary in Retroversion of the Uterus and the Mechanism of its Support.
J. Riddle Goffe, New York.

Utero-Vaginal Prolapse in Elderly Women.
George B. Somers, San Francisco.

Relation of Appendicitis to Adnexal Inflammation of the Right Side.
H. J. Boldt, New York.

Special Considerations in the Surgical Treatment of the Female Pelvic Organs.
Henry Parker Newman, San Diego, Cal.

Proper Operative Period and Methods of Drainage in Pelvic Infections.
L. G. Bowers, Dayton, O.

The Employment in Abdominal Surgery of Two Rubber Drainage Tubes with a Single Stab Wound Exit, Instead of a Single Tube with Exit by Incision or Otherwise Wherever Drainage is Desired.
Philander A. Harris, Patterson, N. J.

Postoperative Complications.
F. F. Simpson, Pittsburg, Pa.

Two Years' Experience with Vaccine in Obstetric and Gynecologic Infections.
John O. Polak, Brooklyn, N. Y.

Primary Carcinoma of the Fallopian Tube.
E. E. Montgomery, Philadelphia.

Prolapse of the Gravid Uterus.
Palmer Findlay, Omaha, Nebr.

Pernicious Vomiting of Pregnancy.
C. B. Ingraham, Denver.

Tuberculosis and Pregnancy.
George C. Mosher, Kansas City, Mo.

A Study of Cholecystitis and Cholelithiasis in Their Relation to Pregnancy.
Laura H. Branson, Iowa City, Ia.

Axis Traction Forceps.
J. P. McMahon, Milwaukee, Wis.

Cesarean Section: Indications and Technic: Report of seventeen cases.
T. Mitchell Burns, Denver.

SECTION ON SURGERY

Chairman, George W. Crile, Cleveland; Secretary, John T. Bottomley, Boston

Brachial Palsy.
Charles H. Frazier, Philadelphia.

Results of Operations on the Gasserian Ganglion for Trigeminal Neuralgia.
Harvey Cushing, Baltimore.

The Advantages of the So-Called Decortication of the Lung for Old Empyemata.
Fred B. Lund, Boston.

Wednesday night a reception in honor of the President will be given at the Shrine Auditorium. This is the most formal social function of the meeting.

Thursday night a smoker and vaudeville entertainment will be given at the Hamburger Roof Garden, Eighth and Broadway, to which everybody is invited.

Friday night there will be a midsummer night carnival at Venice and Ocean Park beaches. These beaches are reached by electric trains from the central station on Hill Street, between Fourth and Fifth.

The afternoon programs for the benefit of the ladies will include a reception and tea at the Hotel Alexandria Tuesday afternoon; an automobile trip about Los Angeles Wednesday forenoon; a garden party on the grounds of Dr. and Mrs. W. Jarvis Barlow in Los Angeles Wednesday afternoon, and Thursday afternoon an Al Fresco Musicale on the grounds of the residence of Dr. and Mrs. Norman Bridge in Los Angeles.

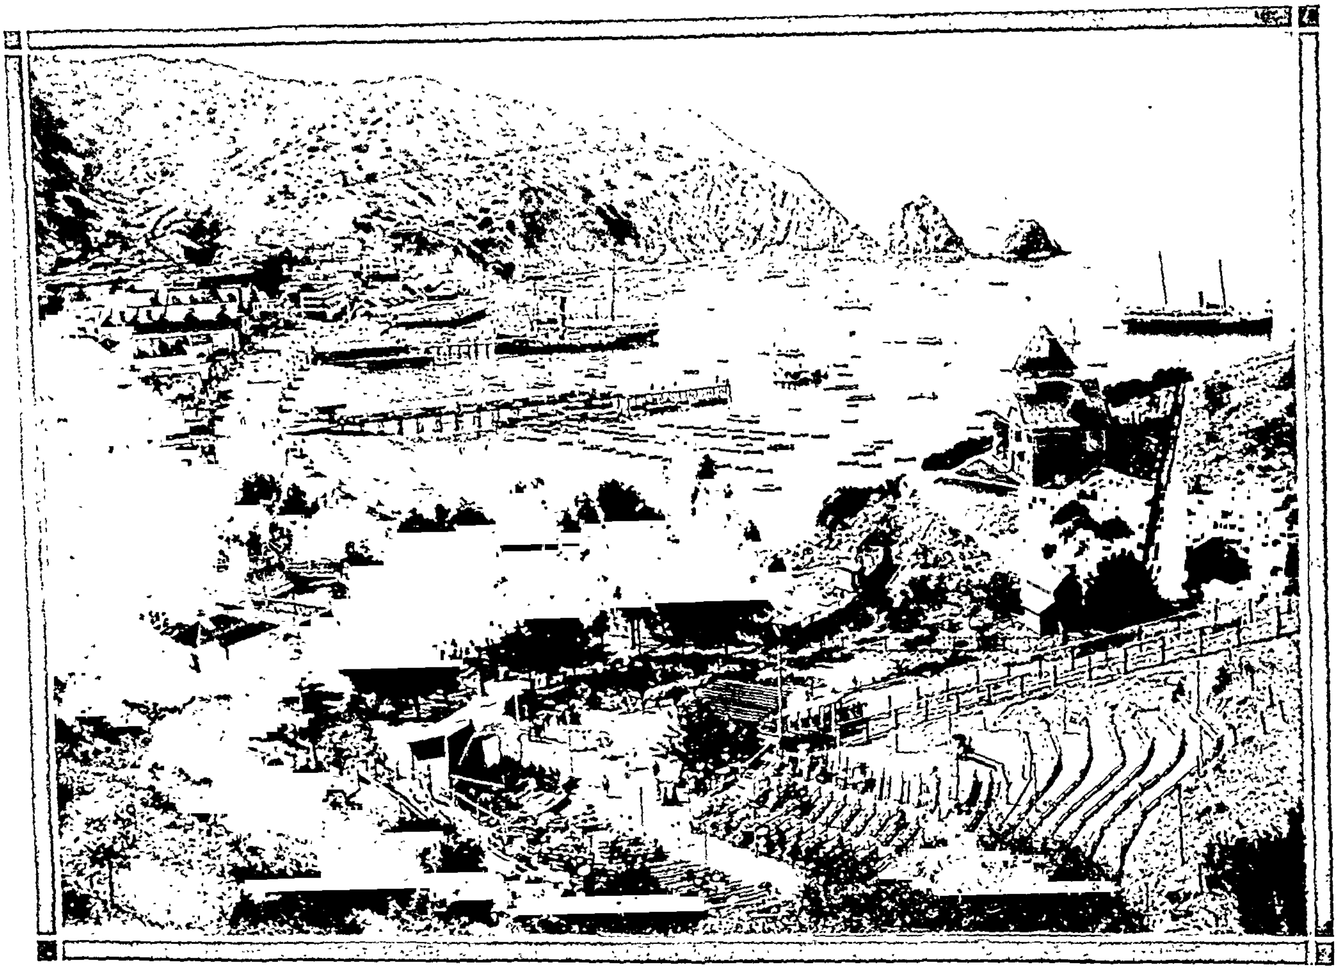

Fig. 17.—View of Avalon and the bay on Catalina Island, twenty miles from the coast of San Pedro harbor. A pleasure trip has been arranged for the members and their friends to Catalina Island. Points of interest on the island are: Sugarloaf Island; Hotel Metropole; glass-bottom boats for observing marine life on the bottom of the bay; Greek theater for band concerts; wireless station.

ENTERTAINMENTS

Social Functions and Amusements Abundantly Provided for the Los Angeles Meeting

An elaborate series of entertainments and amusements has been provided for the members and the visiting ladies during the meeting. The evening entertainments will be as follows:

On Monday night there will be banquets and smokers of several of the auxiliary societies which meet a day ahead of the American Medical Association.

Tuesday night will occur the banquets, smokers and vaudevilles of the sections and the various college classes, etc. The places and times of holding these entertainments, and further details, will be announced later, or on arrival at the meeting.

On Friday a Spanish luncheon and flower fête will be given at noon in the Sunken Gardens in Pasadena. These gardens comprise eighty acres and are acknowledged to be the most beautiful in America. Views of the gardens will be found in this issue. Following the luncheon, there will be Roman chariot races and a wild west tournament at Rose Tournament Park in Pasadena. This will be a unique entertainment. Automobiles will be provided to carry the visitors to the Sunken Gardens and to the park.

On Saturday, and on Friday also, there will be trips to Catalina, the magic island of the Pacific, with side trips in the glass bottom boats to the famous deep sea gardens. A typical Spanish barbecue will be given to the guests on both days. Another point of interest on the island is the Seal

Rocks. The fishing, which is famous at Catalina, will also attract many.

On Saturday also, there will be trolley trips to Long Beach, with luncheon at the Hotel Virginia, and a trip to Los Angeles harbor at San Pedro, with a cruise on the boats of the South Coast Yacht Club.

Other trips to surrounding resorts and cities may be made on Saturday and Sunday, or at any time during the week.

Southern California is a holiday country and there is no end of entertaining trips that may be taken through the orange groves, to the mountains or to the San Gabriel valley and the old San Gabriel Mission.

COMMITTEE ON BUREAU OF INFORMATION

Chairman, Dr. J. Y. Oldham, 214 Grant Building.

COMMITTEE ON RECEPTION AT RAILROAD STATION

Chairman, Dr. Earl Sweet, 823 Story Building.

COMMITTEE ON HOTELS AND HEADQUARTERS

Chairman, Dr. W. LeMoyne Wills, 540 Wilcox Building.

COMMITTEE ON HALLS

Chairman, Dr. John T. Ferbert, 222 Bradbury Building.

COMMITTEE ON SECTION MEETING PLACES

Chairman, Dr. Albert Soiland, 916 Wright & Callender Building.

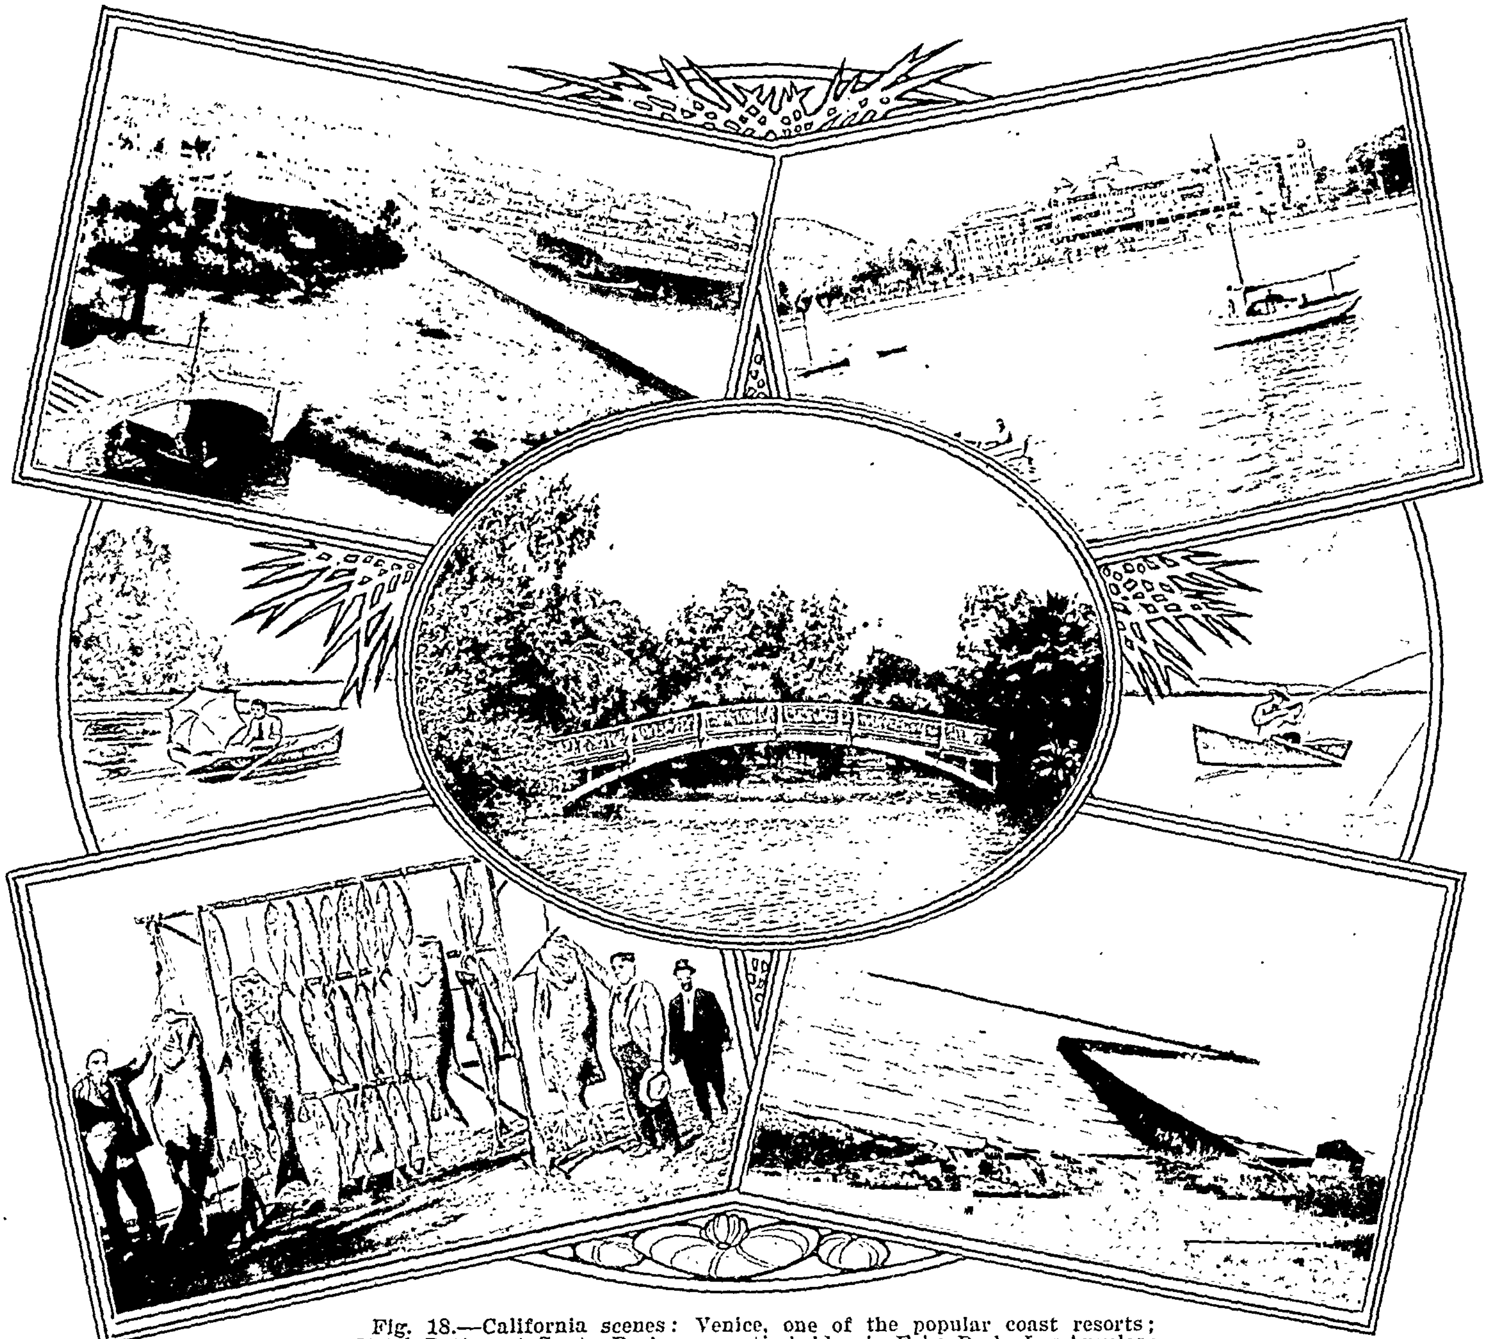

Fig. 18.—California scenes: Venice, one of the popular coast resorts; Hotel Potter at Santa Barbara; rustic bridge in Echo Park, Los Angeles; a day's catch of fish at Catallina; view of the government breakwater at San Pedro, nearly 10,000 feet in length; cost nearly $3,000,000.

COMMITTEE ON ARRANGEMENTS

The central office of the Los Angeles Committee on Arrangements is at 240 Bradbury Building, Third and Broadway, and is in charge of Dr. H. Bert. Ellis, Chairman, and Dr. George H. Kress, Secretary.

CENTRAL EXECUTIVE COMMITTEE

General Chairman, Dr. H. Bert. Ellis, 245 Bradbury Building; General Secretary, Dr. George H. Kress, 240 Bradbury Building; Treasurer, Dr. Walter Lindley; Dr. Fitch C. E. Mattison, Pasadena; Dr. W. Jarvis Barlow.

FINANCE COMMITTEE

Chairman, Dr. F. C. E. Mattison, Chamber of Commerce Building, Pasadena.

Vice-Chairman, Clarence W. Pierce.

Section on Practice of Medicine, Dr. Dudley Fulton.

Section on Surgery, Dr. E. R. Smith.

Section on Obstetrics and Diseases of Women, Dr. M. L. Moore and Carl Kurtz.

Section on Ophthalmology, Dr. T. J. McCoy.

Section on Stomatology, Dr. J. Franklin Cook.

COMMITTEE ON POST-OFFICE, TELEPHONES, ETC.

Chairman, Dr. C. B. Nichols, 721 Grant Building.

COMMITTEE ON REGISTRATION

Chairman, Dr. W. W. Beckett, 213 Exchange Building.

COMMITTEE ON COMMERCIAL EXHIBIT

Chairman, Dr. W. H. Kiger, 306 Conservative Realty Building.

COMMITTEE ON PRINTING

Chairman, Dr. J. H. Seymour, 311 Grant Building.

COMMITTEE ON PROGRAM

Chairman, Dr. O. O. Witherbee, 606 Auditorium Building.

COMMITTEE ON BADGES

Chairman, Dr. F. M. Pottenger, 1202 Union Trust Building.

COMMITTEE ON NON-AFFILIATED ASSOCIATIONS

Chairman, Dr. Granville MacGowan, 602 Lissner Building.

COMMITTEE ON SMOKER ENTERTAINMENT

Chairman, Dr. Chas. W. Bryson, 402 Delta Building.

COMMITTEE ON SECTION ENTERTAINMENTS

Chairman, Dr. Andrew Stewart Lobingier, 609 H. W. Hellman Building.

COMMITTEE ON PRESIDENT'S RECEPTION

Chairman, Dr. W. Jarvis Barlow, 616 Security Building.

COMMITTEE ON PRESS AND PUBLICITY

Chairman, Dr. George H. Kress, 240 Bradbury Building.

ASSISTANT EDITOR OF THE BULLETIN

Dr. Donald J. Frick, 815 Wright & Callender Building.

COMMITTEE ON SCIENTIFIC EXHIBIT

Local Representative, Dr. Stanley P. Black, 424 Auditorium Building.

COMMITTEE ON ENTERTAINMENT OF LADIES

Mrs. Walter Lindley, 2007 South Figueroa Street.

REGISTRATION

Importance of Registering Early

The Registration Headquarters will be found in connection with the Scientific Exhibit, the Postoffice and Commercial Exhibit on the fourth floor of the Hamburger Building, at the corner of Eighth Street and Broadway, easily accessible from hotels and meeting places, or by the car lines from the depots by those who wish to go there directly.

It will be necessary to register in order to obtain the official badge and program. No one will be admitted to any entertainment without a badge. Members are urged to register as soon as they can name their hotels.

The Registration Department will be open from 8:30 a. m. to 5:30 p. m., on Monday, Tuesday, Wednesday and Thursday, June 26, 27, 28 and 29, and from 9 to 10 a. m. on Friday, June 30.

Attention is called to the following directions:

1. Each physician desiring to register will first fill out a registration card. One should write very plainly, or print, as the cards are given to the printer to use as "copy" for putting the names in the daily *Bulletin*.

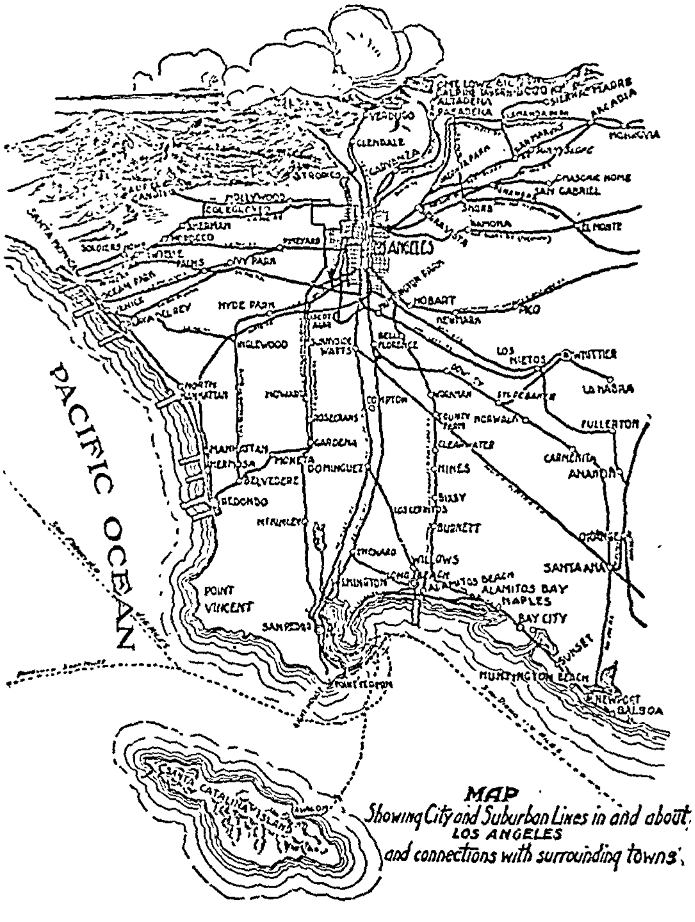
2. *Each member who has paid his annual dues* in full will present his pocket card (which was sent him from the Chicago office) and his filled-out registration card at a window marked "Registration by Pocket Card."

3. *The registration of members* who have paid their dues, but *who have failed to bring their pocket cards*, will be delayed, while the records are consulted. Hence, be sure to bring your "pocket card."

4. *Members who have not paid* their dues will present registration card and make payment at a window marked "Cash."

5. *Each applicant for membership* will present his registration card at the window marked "New Members," with a certificate of membership in his state society. Prospective members, however, will save delay and annoyance by sending in their applications before the session. All such applications should be mailed to the American Medical Association, 535 Dearborn Avenue, Chicago, so as to arrive not later than June 15.

6. Each member on registration will receive a badge, a copy of the Official Program, containing the full details of the scientific proceedings, invitations to the social functions, and such other announcements as may be necessary.



MAP
Showing City and Suburban Lines in and about LOS ANGELES and connections with surrounding towns.

INFORMATION FOR ARRIVING MEMBERS

The three transcontinental lines which come into Los Angeles are the Southern Pacific Railroad, the Santa Fe Railroad and the Salt Lake Railroad.

Arrangements will be made to have local committeemen at each of these depots. The cars which pass these depots take one to the heart of the business and hotel districts. A reference to the map in this issue showing the different streets and the locations of the hotels and meeting places will make the transfers easy.

The street cars coming from the Santa Fe and the Salt Lake railroads nearly all go south on Broadway, Spring or Main streets, so that one has simply to remember the numerical street number where one wishes to get off. The cars from the Southern Pacific run west and reach the hotel district in the neighborhood of Fourth and Fifth and Spring streets.

Those who arrive in the daytime, if they wish, can take the cars at the Santa Fe and Salt Lake stations and go direct to the Bureau of Information on the fourth floor of the Hamburger Building, which is the block bounded by Eighth, Broadway and Hill streets.

INTESTINAL ANAEROBES

The problem of the intestinal anaerobic bacteria, though one of enormous complexity, has been attacked by many investigators, and results both interesting and valuable have been obtained. Passini[1] in a recent article has reviewed some of these, and while space will not permit an enumeration of the various workers, their results are of such interest as to warrant their presentation here.

The meconium of the new-born child, as might be expected, is sterile. But in a few hours, depending largely on the child's environment, microorganisms appear in it, and even among these early invaders anaerobic bacteria take an important part. The gas bacillus (*B. welchii*) appears to be the most constant and important of these. With the ingestion of mother's milk the intestinal flora alters, the chief anaerobe now present being the so-called *Bacillus bifidus*, an organism closely akin to, if not identical with, the familiar Oppler-Boas bacillus. Subsequent alterations in food evoke changes in the bacteriology of the child's intestines, and it is only with the adoption of adult diet that the bacteria assume the corresponding type.

Of the various anaerobes the greatest amount of work has been devoted to the butyric-acid-forming group, of which the gas bacillus is a typical example. As with organisms of the colon group, it has been found that the different members, while fairly sharply differentiated from one another, possess intervening types that would make any precise classification a matter of difficulty. Again, as with the colon group, it has been found possible with these bacteria to demonstrate the phenomenon of group agglutination, and thus to support the idea of kinship between the various individual organisms.

The pathologic significance of the anaerobic intestinal flora offers a still comparatively unexplored field. Numerous experiments have led to the belief that bacterial invasion of the alimentary tract is in the main distinctly beneficial, and apparently it is only when certain organisms become unduly predominant, or altered nutrition affords opportunities for abnormal activity of special organisms, that direct harm results. The problems confronting the investigator in this field are of unusual difficulty, and definite etiologic relationships between specific diseases and anaerobic intestinal infections cannot be regarded as absolutely established. Several instances, however, of fairly constant association of the one with the other, are known. Thus Herter[2] has found that primary anemias of the pernicious type are ordinarily associated with predominance of *B. welchii* in the feces. And so, too, the so-called "enteric catarrh" of infancy has received much attention from this point of view. This alimentary disorder follows as a rule on an excessive sugar diet. In the normal infant, sugar digestion and absorption are practically complete before the lower small intestine is reached; but with large amounts of sugar in the diet, this is no longer the case, and an abnormal medium is provided for the anaerobes inhabiting this part of the alimentary tract. Now it has been found that with special media—essentially albuminous material subjected to tryptic digestion, with subsequent addition of sugar—the gas bacillus is capable of producing a substance violently poisonous, in suitable, though small, doses to laboratory animals. It produces rapid death by paralysis of the respiratory center when given intravenously; and when it is injected into the intestines of dogs, violent peristalsis ensues, with temporary recovery and late death from a hemorrhagic inflammation of the intestinal mucosa. When this substance is applied locally to smooth muscle, tetanic contractions of long duration result. It is, of course, unsafe to ascribe to the action of this poison the human clinical picture. But in favor of this view are the following facts: First, in the stools of enteric catarrh the prevailing organism appears to be the gas bacillus; second, the disease occurs, for the most part at least, in cases of excessive sugar-feeding; third, elimination of sugar from the diet, along with improvement in the patient, is accompanied by a change in the intestinal flora, the spore-free sugar-fermenting type of the gas bacillus giving place to the sporing form, typical of growth in sugar-free media; and fourth, on one occasion at least it has been possible to obtain the characteristic poison by alcoholic extraction of the stools in this disease. The poison thus possibly at the bottom of enteric catarrh is apparently not a toxin in the bacteriologic sense. It is relatively very stable to heat and preservation; it can be extracted with alcohol; and attempts to obtain an antitoxin have been unsuccessful. In its formation, the presence of both sugar and the products of tryptic digestion appear to be essential. Whether or not this toxic substance is identical with the butyric acid produced by the organism, cannot be regarded as absolutely settled. McCampbell[3] obtained as poisonous an effect from solutions of butyric acid of strength equivalent to that of the bacterial cultures as from the filtered cultures themselves; but Passini states that neutralization or even alkalinity of his special medium has no effect on the toxicity.

---

[2] Herter: Jour. Biol. Chem., 1906, ii, 1.

[3] McCampbell: Jour. Infect. Dis., 1909, vi, 537.

It is unfortunate that the connection between the results of the laboratory and the clinical pictures is in part at least conjectural. The necessity for further work is of course obvious; but the results hitherto obtained, though not in themselves conclusive, are of such a nature as to invite the investigation that must lead toward ultimate solution of the problems presented.

EUROPE IN ADVANCE OF US—A TRIBUTE TO HERMANN KNAPP

The recent death of Dr. Hermann Knapp has occasioned a reflection not complimentary to the American people. Before he began his American career he had studied in several European universities, and had established a dispensary and hospital for eye diseases which is now a part of the University of Heidelberg, at which he taught four years. The science and the art of ophthalmology in this country were indeed a puny pair of twins until 1868, when Knapp brought us the ophthalmoscope which his teacher, von Helmholtz, had invented seventeen years before, and which von Graefe—of whom Knapp was also a student—had applied to eye diseases. Thus, Knapp's advent among us initiated the special work in orbital practice by which such beneficent results are now every day in evidence.

Soon after he established himself in New York, Dr. Knapp founded the New York Ophthalmological and Aural Institute, where under him many of the foremost workers in eye diseases in this country received their early training. Himself an extensive producer of papers, treatises and text-books, he began those *Archives of Ophthalmology and Otology* which are to-day an imposing monument to his zeal for the dissemination of the best literature in this special field. The span of his life was eight decades; and from his youth almost to his death, he gave to humankind the best of his heart and mind and strength; night and day he worked, sustained by a most inspiring enthusiasm for his calling and for humanity, until several years ago his health quite gave way; the prosperous and the penniless received alike his equal ministrations.

Now, outside his profession, the American people, whom he served with such self-abnegation, have permitted the occasion of his death to pass practically unnoticed; the representative lay press has given his career not nearly as much space as would be devoted to that of a pugilist or a second-rate politician. True, there was that in Dr. Knapp's fine temperament which lent itself to effacement; he shrank ever from ostentation. It was sought repeatedly to give dinners in his honor, to celebrate his anniversaries; on his retirement from the faculty of the College of Physicians and Surgeons the students wanted to commemorate his services; but he would have none of that. For his seventieth birthday a like celebration was planned; but he kept out of the way until the day and the occasion had passed. Loving-cups, engrossed resolutions and the like are indubitably good in their way; but they were not in Dr. Knapp's way.

Now to the point: had Dr. Knapp died in Germany or in France, his beneficent life and labors would have been the themes of grateful and nation-wide eulogy. For example, in Paris, Berthelot was laid in state in the Pantheon, a great assembly giving its presence, the president of the republic, the diplomatic corps, members of the French Academy, judges, deputies, senators, deputations from many societies, taking part; the French Minister of Education related impressively the dead chemist's achievements; the whole Parisian garrison defiled before the catafalque; on that day every school in France was closed.

The honor paid the memory of Pasteur is another instance: There was several years ago a *plébiscite* to determine who were the ten greatest Frenchmen of the nineteenth century; 15,000,000 votes were cast. Who was first? Napoleon? No. Victor Hugo? No. Pasteur headed the list; among the ten were Curie and Roux; Ampère came eleventh; and Arago, the physicist, was fifteenth.

Virchow's funeral was most impressive, in that the whole German people took part. Von Bergman died in Berlin; but on his seventieth birthday (without waiting to bestow posthumous honors, and while he was still in the plenitude of his powers), his fellow-countrymen, both professional and lay, gave him the fullest meed of respect and affection; about forty delegations, bringing gifts of all kinds, consumed nearly five hours in passing before him. The imperial government, and the great seats of learning were represented; men notable in the arts, in music and the drama, and in other lofty pursuits paid tribute to his sympathetic appreciation of professions other than his own; four important works were prepared and published in commemoration of this great birthday.

Thus do they honor science and the humanities on the Continent. We, it would seem, have still considerable progress to make before we reach a like stage in civilization.

THE WISCONSIN PURE FOOD LAW NOT EMASCULATED

Twice before we have called attention to the fact that the people of Wisconsin are not willing to allow the "interests" to dictate to them the terms of their pure food law. When the federal Food and Drugs Act went into effect the "glucose trust" protested against Dr. Wiley's ruling that the company must label its product "glucose," insisting that it should be permitted to use the more euphemistic term, "corn syrup." Its protest was heeded, Dr. Wiley was overruled, and the first breach in the federal Food and Drugs Act was made. The Wisconsin pure food law also requires that the manufacturer tell the truth on his labels and the officers that enforce this law have insisted that glucose should be called glucose. In this case, also, a protest was made by the trust, but Wisconsin was not so easily cajoled as was Washington. Finding its protest of no avail the "glucose trust" declared a boycott against the state and refused to ship its product into Wisconsin and, what was of still greater moment, it practically ceased advertising in the newspapers of Wisconsin. But the fact that, previous to the boycott, Wisconsin had purchased thousands of pounds of glucose and was therefore a profitable market, caused the makers of this substance to bring to bear all the pressure they could to change the Wisconsin law.

During the early days of the present session of the Wisconsin legislature two bills were introduced by Mr. Perry and Mr. Stevenson, respectively, each having for its purpose the legalizing of the term "corn syrup" as a synonym for glucose. One of these, the Stevenson bill, was withdrawn from the committee and from the assembly, but there was a public hearing on the other. The Perry bill was reported back to the assembly for passage. When the measure came up in the assembly for action on the report of the committee, the bill was killed by the vote of 68 to 22.

This result is cheering to all who believe that pure food laws should be passed and enforced in the interest of the public rather than in the interest of manufacturers. As we have said before, Wisconsin is to be congratulated not only on having an enlightened legislature and a supreme court that interprets the law in the public's interest, but also on having virile and fearless officials who enforce the law without fear or favor.

It now remains to be seen whether the boycott, which the manufacturers of glucose declared, but which was raised during the time that the present legislature was in session, will again be declared against Wisconsin. If a few more states could be prevailed on to insist on the same degree of honesty on the part of manufacturers that Wisconsin requires, it would be but a short time before the Corn Products Refining Company would be only too pleased to label its products "glucose" in accordance with the facts. In the present more or less chaotic condition in the various state food laws, one unfortunate feature is the unfair commercial advantage that a state having loosely liberal laws has over those states which try to protect their citizens by making stringent laws and enforcing them strictly. If competition in the manufacture of glucose were commercially practicable, a boycott on the part of the glucose trust would not be of any great moment, as men of capital would undoubtedly recognize the commercial possibilities of manufacturing glucose within the boycotted state and selling it under its true name. Unfortunately, competition against a practical monopoly, said to be backed by the Standard Oil interests, is probably not commercially practicable.

Against the use of glucose, *per se,* as a food product. we know of no great objection. It is a very inexpensive substitute for real syrup and undoubtedly has a definite food value. Of course, practically all the flavor possessed by the so-called corn syrup preparations, is due to the admixture of cane or some other real syrup with the glucose; for in its pure state glucose is insipid and but very slightly sweet. The fraud on the public consists in selling glucose under the name "corn syrup," for it is not a syrup in the sense understood by the public, namely, the concentrated sap of a sugar-producing plant. The makers of glucose have argued that the word "glucose" is in such ill repute that people will not purchase it under its own name. If this is true, it is all the more reason why the public should not be deceived into purchasing, under a euphemistic name, a substance that they otherwise would not have.

The Corn Products Refining Company, popularly known as the "glucose trust," would have exhibited greater foresightedness and more long-headed business sense if, instead of lobbying against certain features of the Wisconsin Pure Food Law, it had spent the same amount of money on a campaign of education by which the public might learn the harmlessness and food value of glucose. We sometimes wonder how long it will be before all manufacturers that have wholesome products will be willing to sell them honestly and on their merits instead of attempting to build up an artificial demand for them by means of falsehood and political chicanery.

THE USE OF ORANGE-RED UNDERCLOTHING IN THE TROPICS

The theory of Woodruff, that the deterioration of the white man in the tropics is due more to the actinic rays of the sun than to exposure to excessive heat, has found many adherents. With the view of ascertaining the truth or falsity of this hypothesis, the experiments conducted in the Philippines by the Medical Corps of the Army were continued for over a year, and the results are embodied in the last annual report of the Surgeon-General of the Army.[1]

Orange-red underclothing and hat-linings were chosen on account of the known resistance of this color to the actinic rays of the sun. The tests were carried out by making comparisons between 500 soldiers equipped with these garments and 500 controls using white, care being taken to choose the two sets of men from the same companies and to divide them in such a way as to make the two groups as nearly as possible equal in physique. The exceptionally weak and those having had long tropical experience were excluded.

A comparison of the sick reports showed insignificant differences between the two groups, except that there was a higher admission rate for heat exhaustion among those wearing the orange-red underclothing than among the controls. Those wearing orange-red suffered more from perspiration than those wearing white, and extensive experiments, both on and off the body, showed that exposure to the sun caused a greater temperature beneath the colored garments than beneath similar white material. The fall in blood-pressure, as well as the increase in red blood-cells and diminution in percentage of hemoglobin which the unacclimated suffer in the tropics, was more apparent among the wearers of the orange-red than among the controls. The former also showed a tendency to lose weight more rapidly than the latter. Fifteen hundred observations showed temperature, pulse and respiration to be slightly higher for the orange-red group than for the controls. The impressions of the individual wearers were, on the whole, decidedly adverse to the colored underwear. There were only sixteen men who preferred it to the white. Fifty-four expressed no choice, but the remainder, constituting nearly four hundred men, expressed their disapproval. The consensus of opinion seemed to be that it was more uncomfortable, the discomfort being, in the main, attributed to the excessive perspiration which it caused. It is significant that no organization commander saw any benefit from its use, and that of sixteen officers who gave it a personal trial there was only one who expressed approval.

---

[1] Report of the Surgeon-General, U. S. Army, 1910, page 118; experiments carried out at certain Philippine posts by Major Collins and First Lieutenants McKenney, Phillips and Cowles.

The medical officers who conducted the experiments reached the general conclusion that the test underclothing was of no material value, but that, on the contrary, it increased the burden of heat which the system was compelled to endure. They are of the opinion that the sun's rays alone are not responsible for the physiologic effects of the climate in the Philippines, and that, even if the actinic rays have any influence at all on the system, the campaign hat and the khaki uniform constitute a sufficient protection against them.

Current Comment

THE PROBLEM OF PURE MILK

In a recent issue[1] we commented briefly on the report of the Philadelphia Milk Commission. At that time the full report was not at hand. It has since been printed, however, and is available for study by those interested in clean, healthful milk, and that should include every citizen, be he health officer or other public official, or private individual. The report may be heartily recommended for study, too, as it covers one of the most searching investigations of this important problem yet published, and sets forth a complete scheme of regulations for the production, transportation, handling and delivery of milk to the consumer, proposes a plan of reorganization of the division of milk inspection of the health department, and reports on chemical and bacteriologic standards. The commission says that the problem of the safeguarding of milk-supplies for municipalities is too large and too serious to be considered solely from the point of view of the effect that regulation might have on the commercial interests involved, which has been the point of view generally adopted hitherto. Bad milk is one of the great factors in the production of the enormous death-rate of infants under one year of age. It also figures largely in the propagation of typhoid fever, diphtheria, scarlet fever and tuberculosis. The regulation of milk production, transportation and subsequent handling, therefore, becomes one of our most serious problems. The investigations of the commission in many instances revealed wretched conditions in all the stages of the milk business from the producer to the consumer; the members say that to permit the continuation of the milk business under existing conditions could only contribute to the mortality of the community. The most valuable feature of the report is not that it exposes and condemns conditions in Philadelphia particularly, but that its findings and its comprehensive plan for remedying them might be applied with but little modification to almost any other city. The report is a valuable municipal text-book on the milk question.

MAKING ROOM FOR CITY PARKS

The growth of many cities in the United States has been so rapid that proper provision has not been made for adequate public parks and breathing-places for the people. Recent agitation for more parks and playgrounds, and for the general sanitation and hygiene of cities, has resulted in the making of parks at enormous expense in the midst of thickly populated districts. In New York City the necessity for further parks and also for greater dockage facilities in the harbor has culminated in a scheme for the creation of a park in the air, so to speak. At the present time nearly the whole of the west side of Manhattan Island is occupied by the New York Central Railroad tracks, and a plan has been devised whereby a space 200 feet wide and several miles long will be converted into additional space for railroads and docks by filling in along the water-front. It is proposed[1] to cover over this entire space by heavy steel and concrete roofing and then to fill in this roof with soil and make a water-front park. Most cities having water-fronts have allowed these naturally advantageous locations for parks to be absorbed by railroads or other industrial enterprises. Chicago, with its wonderful water-front on Lake Michigan, has allowed this to happen, to a certain extent. The plan of New York, though an expensive one, seems to be entirely feasible; at least, it has been so pronounced by engineers. Certainly it would form a most attractive addition to the park system of that city.

FREE DISPENSARIES FOR HOOKWORM DISEASE

The idea of the free dispensary as a factor in suppressing hookworm infection originated in Mississippi, where the first institution of this kind was organized at Columbia, Marion County, in December, 1910, and is now running a full capacity of 300 patients monthly. The Columbia Dispensary is supported by public and private cooperation, the county health officer having given the use of a four-room building for twelve months, the necessary drugs being supplied by the county board of supervisors, while the beds and other hospital appointments are furnished by the Columbia County Club, and the linen by the women's clubs of the city. A trained nurse has been installed to take care of the dispensary and its patients and people are now coming in for examination and treatment from a radius of over twenty miles. Resting as well as ambulant patients are treated and applications for beds are now sent in well in advance. The Mississippi idea has already begun to take root in other southern states. In Alabama, for instance, there are four dispensaries in Geneva County, five in Dale County, three in Coffee County and two at Houston. Very significant are the results already obtained at the "free clinics" in Coffee County, which are hardly a month old. A circular distributed through the county in March announced that free clinics for hookworm patients would be held at Elba, Brockton and Enterprise at stated intervals. Up to April 14, the total number of patients treated at the three clinics was 1,416, and on one day (April 8) as many as 439 patients applied for treatment at Enterprise alone. In addition, two local county newspapers have engaged to mail 1,000 copies each of a folding circular on sanitary privies to their subscribers. We congratulate the public health authorities of these southern states on the important sanitary work they are doing and hope their example will stimulate other states to similar efforts in the same direction.

PERSECUTION OF DR. KANTOR, THE FOE OF QUACKERY

We have frequently had occasion to commend the organ of the German Antiquackery Society, the *Gesundheitslehrer,* published by Dr. Kantor of Warnsdorf, Bohemia. Dr. Kantor has often been sued for damages by persons and firms injured by his propaganda for reform and exposures of fraudulent proprietaries, and he still has a number of suits on hand. An anonymous pamphlet calumniating his personal and professional character has recently been scattered broadcast. As the slandered physician has no means of legal redress against the authors or instigators of this attack, he has sent to the medical press a reply denouncing the pamphlet as a collection of falsehoods and perversions of fact intended to discredit him, both professionally and as the publisher of the *Gesundheitslehrer.* He adds that, notwithstanding the numerous suits that have been brought against him, no one has succeeded in producing any evidence of dishonorable conduct on his part, either private or professional, and that moneyed interests are bringing every means to bear in order to down him, or to disgust him with his difficult struggle against quackery. His sturdy little monthly costs only seventy-five cents a year and contains a fund of information, written in popular German, on nostrums and different phases of the practice of medicine by unqualified persons. It is to be hoped that Dr. Kantor will receive still more of the support of the German medical profession and of the intelligent lay public in his campaign against the nostrum evil. For a private individual to oppose single-handed the powerful interests involved requires courage and determination of a high order, since the attempt would appear hopeless to an ordinary character. We in America may congratulate ourselves at least on the fact that the organized medical profession has taken a firm stand on the subject, in which it has been sustained by the more progressive portion of the lay press.

Medical News

ARKANSAS

State Medical Society Meeting.—The thirty-fifth annual meeting of the Arkansas Medical Society was held in Fort Smith, May 2-5, under the presidency of Dr. Robinson C. Dorr, Batesville. Hot Springs was selected as the place of meeting for 1912, and the following officers were elected: president, Dr. Morgan Smith, Little Rock; vice-presidents, Drs. James B. Roe, Calico Rock; William W. York, Ashdown, and John W. Webster, Siloam Springs; secretary, Dr. Clinton P. Meriwether, Little Rock; treasurer, Dr. John S. Wood, Hot Springs; delegate to the American Medical Association, Dr. Gus A. Warren, Black Rock; alternate, Dr. John W. Webster, Siloam Springs, and councilors, first district, Dr. Hughey, Knoble; second district, Dr. James H. Kennerly, Batesville; third district, Dr. Tillman B. Bradford, Cotton Plant; fourth district, Dr. Arthur D. Knott, Wilmot; fifth district, Dr. Robert A. Hilton, El Dorado; sixth district, Dr. Leonce J. Kosminsky, Texarkana; seventh district, Dr. Reuben Phillips, Malvern; eighth district, Dr. A. H. McKenzie, Dardanelle; ninth district, Dr. Frank B. Kirby, Harrison, and tenth district, Dr. Matt S. Dibrell, Van Buren.

CALIFORNIA

Builds Sanatorium.—Dr. G. Richard Hickok, Gardnerville, Nev., is about to establish a tuberculosis sanatorium at Badger, 35 miles northeast of Visalia, and has purchased 880 acres as a site.

Illegal Practitioner Sentenced.—Mrs. Salvatrice Mingilino, San Francisco, arrested at the instance of the State Board of Medical Examiners, is said to have been found guilty of practicing medicine without a license and to have been fined $100, with the alternative of fifty days imprisonment in the county jail.

Personal.—Dr. Charles F. Whitmer, Oakland, fell from a tree, May 2, fracturing his left leg.——Dr. Stanley P. Black has been appointed city health inspector of Pasadena.——Dr. William R. Dorr, warden of the City and County Hospital, San Francisco, has resigned.——Dr. George B. Walrath, Los Angeles, while attempting to board a rapidly moving car at Venice was thrown to the ground, fracturing several ribs.——Dr. Edgar W. Clark, Los Angeles, is reported to be seriously ill at his home.——Dr. Charles C. Browning, Monrovia, while in attendance at a meeting of the State Board of Health at Santa Barbara, had an attack of acute appendicitis and was taken to the Good Samaritan Hospital, Los Angeles, where an operation was performed April 20.

Tuberculosis Bill Passed.—Assembly Bill No. 821, introduced by Assemblyman Bliss at the instance of the Alameda Society for the Study and Prevention of Tuberculosis, was passed by the legislature and signed by the governor. The purpose of the new law, which carries with it an appropriation of $5,000, is set forth in the first two sections of the bill, which read as follows:

> Section 1.—It shall be the duty of the State Board of Health to cause special investigation of the prevalence of tuberculosis in California and the effects of localities, employments, conditions and circumstances on the health of those developing the disease, and to determine the best means for its eradication.
>
> Sec. 2.—The State Board of Health shall publish or procure and distribute free to the people of the state of California printed matter, charts, pictures or models, or demonstrate to them in any practical way the prevalence of tuberculosis, the danger of infection therefrom and the means of prevention.

COLORADO

Asks Wards for Drug Addicts.—Dr. Elizabeth Cassidy recommended to the Board of County Commissioners of Denver County that wards at the county jail be set aside for users of cocain, morphin, opium and other drugs, and that the older addicts be segregated from the beginners.

Grants Petition.—District Judge Allen has granted the petition of Dr. Elizabeth Cassidy, Denver, a member of the Board of County Commissioners, to have the proceedings of the board for several months investigated by the district court. Dr. Cassidy's advocation contends that the board is wasting at least $30,000 annually, and that claims are not carefully investigated before payment.

Personal.—Dr. Elizabeth C. Cassidy, Denver, has been appointed a member of the State Board of Charities and Corrections.——Dr. Paul S. Hunter, Denver, has been appointed secretary of the State Board of Health.——Drs. W. W. Flora, Colorado Springs, and George Sullivan, Victor, have been made members of the Board of Dental Examiners, and Dr. Charles

S. Morrison, Colorado City, has been appointed a member of the Lunacy Commission.——Dr. Edgar D. Heaton, Centerville, Ia., was thrown from his bicycle, April 27, fracturing his right arm below the elbow.——Dr. Sherman Williams, Denver, has been appointed a member of the State Board of Health, vice Dr. Minnie C. T. Love.

ILLINOIS

State Board Prosecution.—L. C. Crump, indicted on charges by the State Board of Health for the illegal practice of medicine, was tried before a jury in the municipal court, Chicago, and fined $100 and costs. The defendant is said to have issued a card setting forth that he is a man of God and a divine healer. He is said to have examined each of those who applied to him, prayed with him, given him a big bottle of medicine and charged $1.

Personal.—Dr. Joseph C. Myers, Clinton, who has been ill in Decatur, has returned home.——Dr. and Mrs. Martin Van Buren Montgomery, Opdyke, celebrated their golden wedding anniversary, May 6.——Dr. Frank L. Hall, Jacksonville, has retired from the practice of medicine.——Dr. Benamjin P. Marsh, Bloomington, is reported to be ill with neurasthenia. ——Dr. Henry J. Gahagan has been named as city physician of Elgin.——Dr. Charles G. Beard, Sterling, has been appointed district surgeon for the Northwestern System, vice Dr. Frank Anthony, Sterling, deceased.

Society Meetings.—At the annual meeting of the Brainard District Medical Society, held in joint session with the Logan County Medical Society at Lincoln, April 27, the following officers were elected: President, Dr. Edwin P. Sloan, Bloomington; vice-presidents, Drs. Charles W. Carter, Clinton; Charles B. Caldwell, Lincoln, and Robert A. Noble, Bloomington; secretary, Dr. Harry S. Oyler, Lincoln; treasurer, Dr. Charles C. Reed, Lincoln, and censor, Dr. Athens L. Brittin, Atlanta.——DeKalb County Medical Association, at its annual meeting held in Sycamore, April 28, elected Dr. Charles H. Mordoff, Genoa, president; Dr. John B. Nesbitt, Sycamore, vice-president, and Dr. Stoddard L. Anderson, DeKalb, secretary and treasurer.——The Elgin Physicians' Club; at its annual meeting, May 1, elected Dr. George J. Schneider, president; Dr. Edward H. Abbott, vice-president; Dr. Jane Trull, secretary and treasurer, and Dr. Charles E. Sisson, a member of the executive board.——La Salle County Medical Society, at its annual meeting held in Ottawa, April 25, elected Dr. Everett H. Butterfield, Ottawa, president; Dr. Milton E. Blanchard, Marseilles, vice-president; Dr. Albert J. Roberts, Ottawa, secretary and treasurer; Dr. George A. Discus, Streator, censor; Dr. William O. Ensign, Rutland, delegate to the state society, and Dr. William Schoenneshofer, Lostant, alternate.

Chicago

Sanatorium Site Chosen.—The Paul Lawrence Dunbar Sanatorium for Colored Tuberculosis Patients will be established on a tract of land nine acres in extent, lying between Washington Heights and Morgan Park.

Playground Established at Hospital.—A playground for the exclusive use of convalescent children has been established by St. Luke's Hospital on a lot 50 feet by 163, adjoining the institution, which has been purchased and will be fenced in and equipped with outdoor gymnastic apparatus.

Suburban Hospital.—Thirty-five physicians of Oak Park, Austin, Elmhurst and Melrose Park met at the Oak Park Club, May 15, and organized the Suburban Hospital Association. The following officers were elected: President, Dr. Charles E. Humiston, Austin; vice-president, Dr. Charles W. Poorman, Oak Park; secretary, Dr. Fred W. Kettlestrings, Oak Park, and treasurer, Dr. Thomas E. Motter, Oak Park. Drs. Humiston, Poorman and William G. Willard were appointed members of the site committee.

Personal.—Dr. Henry J. Pieper, of the University of Chicago, has been appointed assistant professor of physiology in Columbia University.——Dr. and Mrs. Eugene S. Talbot and daughter sailed for Europe, May 20.——Dr. Fenton B. Turck gave a reception to the class of 1891 of Northwestern University Medical School at his house, May 6.——Dr. John B. Murphy is reported convalescent after an attack of typhoid fever. ——Dr. Walter B. Schwuchow has moved to Los Angeles, Cal. ——Dr. Samuel W. Forney has moved from Chicago to Boise, Ida.

INDIANA

Alumni to Meet.—The Alumni Association of the Indiana University School of Medicine will hold its annual meeting at Indianapolis, May 29. In the evening a banquet will be given at the Columbia Club.

Fly Catechism.—Dr. Charles S. Woods of the City Sanatorium of Indianapolis distributed 30,000 leaflets to the school children of that city on the care of the teeth and also a fly catechism dealing with the province of the ills due to the house fly.

Handling of Foodstuffs.—At a special meeting of the State Board of Health, three rules were added to the regulations for the handling of foodstuffs. The first provides that hotels and restaurants shall be classified as cold storage plants, except when the storage is less than thirty days. The other two rules refer to the handling of dairy products in unsanitary dairies or manufactories, and provide that it becomes a violation of the law for milk, butter, cheese or other milk products to be offered for sale when the product is from an establishment that has been condemned by the board.

Personal.—Dr. Mary E. Jackson, Hammond, who was operated on at the Mary Thompson Hospital, Chicago, for the removal of gall-stones, has returned to her home, convalescent. ——Dr. Stanley W. Edwins, Elwood, has retired after fifty-five years of practice.——Dr. Orange G. Pfaff, Indianapolis, who has been ill for several weeks from septicemia is convalescent and has gone to Atlantic City.——Dr. Fairfield Snyder, Corunna, has been declared of unsound mind and application has been made for his admission to the Longcliffe Hospital. ——Dr. James Trelor Tresidder, Tipton, has gone to Indianapolis for operation.

State Board Prosecutions.—Dr. Rudolph C. Tilley, who is said to have taken two examinations before the State Board but failed to obtain the proper certificates, was arrested on the charge of practicing medicine without a license at Lawrenceburg and fined $25.00 and costs.——At a meeting of the State Board of Medical Registration and Examination, May 11, the license of Dr. William McKinstray, South Bend, is said to have been revoked on an affidavit filed by Dr. Alexander P. Forbes Gammack, and afterward verified, which stated that Dr. McKinstray had purchased his diploma from the National Medical University of Chicago.

MARYLAND

Officers Hold Over.—Under an amendment to the constitution adopted at the late meeting of the Medical and Chirurgical Faculty of Maryland, the new officers will not assume their duties until Jan. 1, 1912, the officers of 1910 holding over until that time.

Personal.—Dr. Henry W. McComas has been elected secretary of the Board of Health of Garrett County and physician to the County Jail, vice Dr. John C. Legge.——Dr. Charles M. Ellis, Elkton, is reported to be critically ill at Johns Hopkins Hospital, following a surgical operation.

Baltimore

Personal.—Dr. Harry Friedenwald sails for Europe, May 13.——Dr. George A. Strauss, Jr., who was operated on at Mercy Hospital, May 7, is reported to be convalescent.——Dr. Marcus S. Dillon has been appointed medical supervisor of the Franklin Square Hospital of the Maryland Medical School, vice Dr. James A. Duff.

Endows Hospital and Industrial School.—James L. Kernan has placed on record deeds of trust whereby the net dividends from 3,400 shares of the capital stock of the James L. Kernan Company will be applied, at his death, to the James Lawrence Kernan Hospital and Industrial School for Crippled Children founded by him at Radnor Park.

Dispensary Election.—At the annual meeting of the board of directors of the Baltimore Eastern Dispensary, held May 8, Dr. Daniel W. Cathell was elected president, Drs. George F. Hancock and Frank C. Bressler were elected directors, and Dr. Robert S. Kirk was reelected superintendent for the twelfth year. During the year just ended, 25,840 patients were given treatment at the institution.

Will Ask Enabling Act.—The Municipal Tuberculosis Commission will ask the next legislature for an enabling act to allow Baltimore to float a loan to provide for a hospital to accommodate three hundred tuberculosis patients. Baltimore is said to have been the first city to inaugurate a systematic fight against tuberculosis. Mrs. William Osler raised a fund and paid a nurse to investigate cases throughout the city and to instruct those afflicted as to their care. The Maryland Association for the Prevention and Relief of Tuberculosis then came into existence and took up the work, employing four nurses. A few years later the work became so heavy that the city was called on to take charge and provided fifteen public nurses, and it is believed that next year twenty-five nurses will be needed.

MASSACHUSETTS

Personal.—Drs. John L. Ames and Arthur B. Coffin, Boston, have resigned as school physicians.——Dr. Patrick H. Mullowney has been appointed a member of the Boston Board of Health.

Physicians to Aid Foreigners.—At the recent missionary jubilee in Boston, a number of women physicians organized the Medical Women's Association for Aiding Women in Medical Work in Foreign Countries; and elected the following officers: president, Dr. Frances M. Morris; vice-presidents, Drs. Helen I. Woodworth and Edith Hale Swift; secretary, Dr. Blanche A. Denig, and treasurer, Dr. Mary R. Mulliner, all of Boston. The object of the association is to raise money to endow already existing medical institutions for women in foreign countries; to provide scholarships for native women in medical schools; to take a personal interest in women medical students who are studying to enter the foreign field, and to provide equipment and hospital facilities as far as possible.

District Society Elections.—At the annual meeting of Essex North District Medical Society, held in Lawrence, May 3, the following officers were elected: president, Dr. Warren W. Pillsbury, Newburyport; vice-president, Dr. William H. Merrill, Lawrence; secretary-treasurer, Dr. J. Forrest Burnham, Lawrence; commissioner of trials, Dr. John F. Croston, Haverhill; nominating councilor, Dr. Israel J. Clarke, Haverhill; alternate, Dr. Charles G. Carleton, Lawrence; supervising censor, Dr. Frank B. Pierce, Haverhill; censors, Drs. Robert M. Birmingham, Lawrence; John A. Magee, Lawrence, John A. FitzHugh, Amesbury, and Thomas R. Healy, Newburyport, and councilors, Drs. Charles G. Carleton, Lawrence, Israel J. Clarke, Haverhill, John A. Douglass, Amesbury, Ernest H. Noyes, Newburyport, Frank B. Pierce, Haverhill, Frank W. Snow, Newburyport, Frederick E. Sweetsir, Merrimac, and J. Forrest Burnham, Lawrence.——At the annual meeting of Berkshire District Medical Society, held in Pittsfield, April 27, the following officers were elected: President, Dr. Clifford S. Chapin, Great Barrington; vice-president, Dr. Isaac S. F. Dodd, Pittsfield, and treasurer, Dr. Joseph D. Howe, Pittsfield. ——At the annual meeting of the Springfield Academy of Medicine, Prof. John M. Tyler, Amherst, gave an address on biology. The following officers were elected: president, Dr. Philip Kilroy; vice-presidents, Drs. Ralph H. Seelye and J. B. Cummings; secretary, Dr. Alexander C. Eastman; treasurer, Dr. John M. Birnie, all of Springfield, and censor, Dr. J. Clark Hubbard, Holyoke.

MICHIGAN

Pays for Registration of Births.—The state has begun the payment of approximately $36,000 to Detroit physicians for registration of births during 1910.

Antituberculosis Work.—At the first regular meeting of the Saginaw Antituberculosis Society, held May 3, Dr. George L. Alger, Saginaw, was elected president, and it was planned to launch an extensive campaign with lectures, literature and personal effort.——An antituberculosis league has been started in Adrian. A committee was appointed on constitution and by-laws on which Dr. Eli T. Morden was made chairman.

Personal.—Dr. Edwin Goodwin has been appointed health officer of Bay City.——Dr. Ross U. Adams, Kalamazoo, who has been in the Borgess Hospital with septicemia, due to an operation wound, is reported to be much improved.——Dr. Clarke B. Fulkerson has been reappointed city bacteriologist of Kalamazoo.——Dr. Jos. B. Griswold, Grand Rapids, has been appointed a member of the Board of Control of the Soldiers' Home in that city.——Dr. William A. Wilson, Detroit, has been reelected national president of the Federation of Florence Crittenton Leagues.

Alumni Week at Detroit.—Alumni week will be celebrated by the Detroit College of Medicine with a series of clinics extending from May 17 to May 25, inclusive. The special features of the week are clinics by Drs. Albert J. Ochsner, Chicago, on "General Surgery;" Jesse S. Myer, St. Louis, on "Cardiospasm;" Emilius C. Dudley, Chicago, on "Gynecology;" George W. Crile, Cleveland, O., on "Surgery;" Jay F. Schamberg, Philadelphia, on "Dermatology;" Charles S. Williamson, Chicago, on "Heart Disease;" Edward L. Keyes, Jr., New York, on "Genito-Urinary Diseases," and William T. Henderson, Mobile, Ala., on "Local Anesthesia in Hernia." On May 19 the alumni will be given a lunch at the Ford Motor factory and in the afternoon will inspect the Walker-Gordon farm near and in the afternoon will inspect the Walker-Gordon farm near Birmingham. On May 23 there will be a boat ride to the St. Clair flats, following an inspection of the research laboratory of Parke, Davis and Company; and on May 25 there will be a luncheon at Harmonie Hall, followed by the annual meeting of the association.

MISSOURI

Hospital Cornerstone Laid.—The cornerstone of the new German Hospital at Kansas City was laid with formal ceremonies, April 30. The building is to cost $150,000 and marks the completion of a quarter of a century's existence of the institution.

Changes in State Institutions.—Dr. Robert Scott Magee, Green City, assistant superintendent of the State Hospital, No. 3, Fulton, has been appointed acting superintendent of the State Hospital, No. 4, Farmington, vice Dr. Robert E. Keaney, Farmington, resigned.——Dr. Porter E. Williams, Clarksburg, with two other members of the State Board of Charities, has been detailed to go to Farmington and make an investigation of the system and methods there in vogue.——Drs. Henry Lloyd and Frank S. Weber, assistants at the State Hospital, No. 4, Farmington, have resigned.

Society Proceedings.—Carroll County Medical Society was reorganized at Carrolton, April 24, and the following officers were elected: president, Dr. Richard F. Cook; vice-presidents. Drs. William C. Baird, Bogard, and Strong. Norborne; secretary and treasurer, Dr. H. Jackson Harrell, St. Louis; delegate to the state association, Dr. Edward H. Musson, Norborne, and alternate, Dr. Rezin C. Shawhan.——At the annual meeting of the Linton District Medical Society, held in Mexico, May 2, the following officers were elected: president, Dr. Robert C. Strode, Mexico; vice-presidents, Drs. August W. Kampschmidt, Columbia, and Frank J. Tainter, St. Charles; secretary, Dr. R. T. Gibbs, Mexico, and treasurer, Dr. Ned R. Rodes, Mexico.

St. Louis

Inebriates' Home.—The St. Louis Society of Medical Research inaugurated a movement at its meeting, May 7, for a state home for inebriates, to cost $100,000. The plan is to establish a colony to which inebriates may be committed for indeterminate sentences.

Personal.—Dr. Henry S. Atkins, superintendent of the municipal sanatorium, has resigned.——Dr. Edward L. Cooley has returned from abroad.——Dr. Max Starkloff, newly appointed health commissioner, has been appointed registrar of vital statistics.

Hospital Board Needs More Money.—The hospital board has asked the municipal assembly to appropriate $200,000 in addition to the appropriation of $700,000 already made, for its uses. This amount is to go toward the maintenance of the City Hospital, the sanatorium, infirmary, Robert Koch Hospital and the city dispensaries.

Research Society Organized.—The St. Louis Society of Research in Tuberculosis was organized April 20. The object of the society is to stimulate research in problems connected both with medical and surgical tuberculosis. Dr. William Porter was elected president, Dr. Louis C. Boisliniere, vice-president, and Dr. Ross Hopkins, secretary.

NEBRASKA

County Society Meeting.—Sherman County Medical Society, at its annual meeting held in Loup City, May 2, elected Dr. Mary A. K. Hendrickson, president; Dr. Archibald J. Kearns, Loup City, vice-president, and Dr. Anton E. Wanek, Ashton, secretary and treasurer.

Rush Alumni of Nebraska Hold Meeting.—The annual meeting of the Rush Alumni Association of Nebraska was held in Omaha, April 30. Dr. John M. Dodson, dean of the college, was the guest of honor and delivered an address on the "History of Rush Medical College." Dr. Frank E. Coulter, Omaha, was elected president, and Dr. Rodney Bliss, Omaha, secretary of the society.

State Association Meeting.—The forty-third annual meeting of the Nebraska State Medical Association was held in Omaha, May 2-4, and the following officers were elected: president, Dr. Andrew D. Nesbitt, Tekamah; vice-presidents, Drs. N. T. Johnston, Upland, and Voorhees Lucas, North Platte; secretary, Dr. Alonzo D. Wilkinson, Lincoln (reelected); treasurer, Dr. Alexander S. Von Mansfelde, Ashland (reelected); chairman of the board of councilors, Dr. Harvey H. Bellwood, Alliance, and delegate to the American Medical Association, Dr. A. R. Mitchell, Lincoln.

College News.—The Nebraska legislature has passed a bill, which has been signed by the governor, appropriating $100,000 with which to begin the development of the campus of the College of Medicine of the State University in Omaha. This is the first step toward the development of a complete medical college plant.——Fire in the elevator shaft of Creighton College, May 8, caused a loss of more than $60,000. The chief damage was caused to the laboratories of the institution.——The commencement exercises of Creighton University were held, April 29, and a class of forty-three was graduated from the medical department.——At the annual meeting of the Creighton Alumni Association, April 27, Dr. Gustav Hahn, Omaha, was elected president, and Dr. Rudolph Rix, Omaha, secretary and treasurer (reelected for the twelfth successive term).

NEW JERSEY

Health Board Reorganizes.—The State Board of Health met for reorganization in Trenton, May 9. J. H. Capstich, Montville, was elected president, and Bruce S. Keater, Asbury Park, was reelected secretary.

Personal.—Dr. Edmund L. B. Godfrey, Camden, has been appointed Surgeon General of the National Guard of New Jersey, with the rank of brigadier general.——Dr. Edward A. Ayers has been appointed president of the Board of Health of Newton.——Dr. David B. Ackley, Trenton, is reported to be ill with septicemia as result of an operation wound of the hand.

Society Meetings.—The Middlesex Medical Society held its annual meeting in New Brunswick, April 20, and elected Dr. John L. Lund, Perth Amboy, president; Dr. Howard Crosby Vorhees, New Brunswick, vice-president; Dr. Martin Stoetzel Meinzer, Perth Amboy, secretary; Dr. David Combs English, New Brunswick, treasurer, and delegates to the state society, Drs. William E. Ramsay and John L. MacDowell, Perth Amboy.——At the annual meeting of the Hudson County Medical Society, held in Hoboken, Dr. George Myrtle Culver was elected president; Dr. Frank F. Bowyer, vice-president; Dr. Charles H. Finke, Jersey City, secretary; Dr. Henry H. Brinkerhoff, treasurer, and Dr. Joseph Abraham Koppell, reporter.——At the annual meeting of the Passaic County Medical Society, held in Paterson, April 11, the following officers were elected: Dr. William S. Flitcroft, president; Dr. Robert Morison Curts, vice-president; Dr. Joseph Allen Maclay, secretary (reelected); Dr. William Wallace MacAlister, treasurer; Dr. Thomas Arthur Clay, reporter; Dr. Charles H. Scribner, censor; Drs. Edgar Carroll Dayton and Joseph V. Bergin, permanent delegates, and Drs. Benjamin H. Rogers, James H. Curts, Frank Joseph Keller, James Alexander Browne, Thomas A. Dingman and Orville Reed Hagen, annual delegates.

NEW YORK

County Society Meeting.—The annual meeting of the Schuyler Medical Society was held in Watkins, May 9, and the following officers were elected: President, Dr. John M. Quirk, Montour Falls; vice-president, Dr. Arthur H. Jackson, Odessa; secretary, Dr. John M. Swan, Watkins, and treasurer, Dr. Delivan W. Scutt, Watkins.

Vetoes Site for City Hospital.—Mayor Furhman has vetoed the West Farm site for the proposed Buffalo General Hospital. This site had been agreed on by all concerned as favorable and contains 81 acres, whereas the site favored by the mayor is the one on which the present Erie County Hospital is located and comprises only 47½ acres.

New Buildings Needed for Sanatorium.—Mountain Sanatorium, Binghamton, is in further need of a building in which patients in advanced stages of tuberculosis, or moribund, may be cared for. The building proposed will be about 24 feet square, with male and female wards, and a room adjoining for the use of the nurse in charge of the building.

New York City

Gift to Columbia.—Columbia University has received an anonymous gift of $10,000 annually for four years, to be used in surgical research.

Personal.—Dr. Winford H. Smith sailed for Europe, May 25. He will assume charge of his duties as superintendent of Johns Hopkins Hospital about the middle of August.——Dr. Edwin H. Fiske, Brooklyn, has been appointed a police surgeon, vice Dr. Charles H. Terry, retired.

NORTH CAROLINA

Personal.—Dr. Francis O. Rogers, Concord, is about to remove to Galveston, Tex.——Dr. Baxter B. Hunter, Kings Mountain, has returned from New York City and is about to reenter practice in Charlotte.——Drs. J. Howell Way, Waynesville, and William O. Spencer, Winston, have been recommissioned members of the State Board of Health for six years.

To Have County Superintendent of Health.—The commissioners of Gilford have decided to elect a county superintendent of health at a salary of $2,500 per annum, requiring the individual so elected to devote his entire time to the care of the inmates of the various county institutions and the instruction of the children in the schools throughout the county in hygienic living.

The Hookworm Campaign.—The campaign against hookworm in the state continues active. Last week Dr. Platt W. Covington, Rockingham, was added to the field force which now includes four traveling physicians under the direction of Dr. John A. Ferrall, assistant secretary for hookworm of the State Board of Health. Six microscopists in the Laboratory of Hygiene at Raleigh are devoting their entire time to the investigation of specimens sent in.

NORTH DAKOTA

Physicians of State Hold Meeting.—The North Dakota State Medical Association held its twenty-fourth annual meeting in Fargo, May 9-11, and elected the following officers: president, Dr. Clinton E. Spicer, Litchville; vice-presidents, Drs. Alexander J. McCannell, Minot; Murdock MacGregor, Fargo, and R. Hudson Beek, Lakota; secretary, Dr. Hezekiah J. Rowe, Casselton (reelected); treasurer, Dr. Frank J. King, St. Thomas (reelected); councilors, Drs. Francis R. Smyth, Bismarck; Henry M. Wheeler, Grand Forks, and Andrew Clark; delegate to the American Medical Association, Dr. Victor H. Stickney, Dickinson, and alternate, Dr. Henry H. Healy, Grand Forks. Valley City was selected as the place of meeting for 1912.

OHIO

Cleveland Personal.—Dr. James D. Pilcher, who was recently operated on for appendicitis, is reported to be making good progress toward recovery.——Dr. Henry J. Gerstenberger has been appointed a member of the Cleveland Milk Commission, vice Dr. Edward F. Cushing, deceased.——Dr. George N. Upson was recently operated on for hernia and adhesions, following appendectomy.

State Association Meeting.—The sixty-sixth annual meeting of the Ohio State Medical Association was held in Cleveland, May 9-11, the Cleveland Academy of Medicine acting as host. The annual address on surgery was delivered by Dr. J. Chalmers Da Costa, Philadelphia, and it was decided to hold the next annual meeting in Dayton. The following officers were elected: president, Dr. Horace Bonner, Dayton; vice-presidents, Drs. Charles B. Parker, Cleveland; John C. Larkin, Hillsboro; George W. Hixson, Cambridge, and Sidney D. Foster, Toledo; councilors, Drs. Dana O. Weeks, Marion, and William E. Wright, Newark; secretary, Dr. John H. J. Upham, Columbus, and treasurer, Dr. Joseph A. Duncan, Toledo. A report of the scientific proceedings will appear in The Journal.

OKLAHOMA

Health Officers Meet.—The Oklahoma State Health Association, at its annual meeting in Muskogee, May 10, elected Dr. W. E. Wright, Tulsa, president; Dr. William G. Blake, Tahlequah, vice-president, and Dr. Joseph C. Ambrister, Chickasha, secretary-treasurer.

Woman's Auxiliary Meeting.—The Woman's Auxiliary of the Oklahoma State Medical Association, at its meeting in Muskogee, May 11, elected Mrs. W. C. Mitchiner, Okmulgee, president; Mrs. David A. Myers, Lawton, and Mrs. Walter B. Reeves, Wapanucka, vice-presidents; Mrs. Patrick H. Mayginnes, Tulsa, secretary and Mrs. John F. Duckworth, Tahlequah, treasurer.

Personal.—Captain Hugh Scott, M.C., N.G. Oklahoma, Waukamis, has been detailed to attend the army maneuvers at San Antonio.——Fire in the Westfall building, Oklahoma City, did great damage to the offices of Drs. Everett E. Phillips and Arthur L. Edington.——Dr. William Ernest Floyd, Coweta, has been appointed physician of Wagner County.

New Medical Examining Board.—The State Board of Medical Examiners held its meeting for organization in Oklahoma City, April 12, and elected Dr. Francis B. Fite, Muskogee, president; Dr. R. Ellis Sawyer, Durant, vice-president; Dr. John W. Duke, Guthrie, secretary, and Dr. F. A. Englehart, Oklahoma City, treasurer.——Dr. Jesse L. Wharton, Duncan, has been appointed a member of the State Board of Medical Examiners, vice Dr. D. C. F. Stillwell, Piedmont.

State Society Election.—At the nineteenth annual meeting of the Oklahoma State Medical Association, held in Muskogee, May 9-11, the following officers were elected: president, Dr. Charles L. Reeder, Tulsa; vice-presidents, Drs. James L. Shuler, Durant; H. Marion Williams, Wellston, and John W. Duke, Guthrie; secretary-treasurer, Dr. Claude A. Thompson, Muskogee (reelected), and chairman of the department on the eye, ear, nose and throat, Dr. W. Albert Cook, Tulsa. Shawnee was selected as the next place of meeting.

PENNSYLVANIA

Personal.—Dr. Oscar Kniffler, Pittsburg, has decided to move to Wiesbaden, Germany, on account of the health of his wife. ——Dr. George G. Harman, Huntingdon, who was operated on for appendicitis in the German Hospital, Philadelphia, March 22, has fully recovered.

Mount Alto Sanatorium.—According to State Health Commissioner Dixon, centralization of the state's tuberculosis work at Mount Alto, Cresson and Hamburg has not only great economic advantage, but also secures much better conditions for the patients under which to make the fight for health. At Mount Alto 800 patients are now being treated and the capacity will soon be raised to 1,200. One central heating plant serves for the entire village, and in the camp for incipient cases, there is a comfortably large sunshiny cottage for every eight patients, two in a room.

Touring Lecturer to be Employed.—At a meeting of the board of directors of the Pennsylvania Society for the Prevention of Tuberculosis, held May 9, it was decided to employ a lecturer to tour the state addressing the school children and teachers on the methods of preventing tuberculosis. Town meetings will be held by him and he will organize a corps of instructors to carry on the work. Plans were also formulated for an organized agitation to obtain county hospitals for advanced cases. Conferences will be arranged with the various county poor boards and a vigorous campaign started in all parts of the state.

Philadelphia

Hospital Building Dedicated.—A large addition to the Mt. Sinai Hospital was dedicated May 6, with elaborate ceremonies. A number of addresses were made and an interesting feature of the program was the sale of the golden keys (of the main door, vestibule, dispensary, various wards, private rooms and clinics) by auction, the twenty keys bringing in a total sum of $3,160.

Personal.—Dr. Warfield T. Longcope has been appointed assistant professor of medicine in Columbia University.—— The vacancy created in the editorship of the *American Journal of the Medical Sciences* by the death of Dr. Aloysius O. J. Kelly has been filled by the acceptance of the position by Dr. George Morris Piersol.——Dr. Herbert P. Leopold sailed for Europe, May 13.——Drs. George G. Ross and Albert D. Whiting have been appointed instructors in surgery at the Medical School of the University of Pennsylvania.——Dr. William M. Sweet has been appointed attending surgeon to the Wills Eye Hospital. to fill the vacancy caused by the death of Dr. Charles A. Oliver.

Urges Use of Byberry.—The Council's committee on health and charities, which made a tour of inspection of insane asylums in other cities, in its report to Councils on May 4, recommended the immediate erection of a hospital for insane at Byberry; the overcrowded condition of the present quarters and the fact that the city is paying for the maintenance of 1,930 patients in other institutions were given as reasons for prompt action. It was suggested that Councils make an appropriation for a temporary building at Byberry to house 400 of the able-bodied insane male patients, who should be put to work preparing the ground for new buildings; that the new institution be built in a semi-detached system, all buildings to be connected by corridors and tunnels; that the institution be equipped with common dining rooms, except in the infirmaries and wards for feeble and unclean cases, kitchen building, laundry, workshops, convalescent building, infirmaries, attendants' homes, recreation buildings, auditorium, chapels, power plant, surgical operating room and a morgue.

TENNESSEE

College Commencement.—The thirty-fifth annual commencement of Meharry Medical College, Nashville, was held April 25. The address to the graduating classes was delivered by Rev. C. T. Walker, Augusta, Ga. This was followed by an address from Governor Hooper. A class of fifty-five was graduated from the medical department.

Society Condemns Hospital Superintendent.—The Memphis and Shelby County Medical Society, at its meeting May 2, went on record as condemning Alvin F. Tate, superintendent of the City Hospital "on account of his personal unfitness, his discourteous treatment to members of the medical profession and his discourtesies to the interns and nurses."

TEXAS

State Association Election.—At the forty-third annual meeting of the State Medical Association of Texas, held in Amarillo, May 9-11, the following officers were elected: president, Dr. David R. Fly, Amarillo; vice-presidents, Drs. Wiley H. Freeman, Lockney; A. L. Lincecum, El Campo, and Joe H. McCracken, Mineral Wells; trustee, Dr. John T. Moore, Houston; councilors, Drs. Hugh D. Barnes, Tulia; Washington A. Harper, Austin; William H. Blythe, Mount Pleasant; Walter Shropshire, Yoakum; Wallace Ralston, Houston, and Newton J. Phenix, Colorado (reelected); delegates to the American Medical Association, Drs. Arthur C. Scott, Temple; Vard H. Hulen, Houston; William L. Brown, El Paso, and Joe Becton, Greenville, and alternates, Drs. Frank D. Boyd, Fort Worth; Charles A. Smith, Texarkana, and James C. Loggins, Ennis. Waco was selected as the next place of meeting. Resolutions were adopted setting forth the necessity for the state to promptly provide adequate room and treatment of the insane of the state so as to avoid the necessity for confinement of insane persons in jails at any time, and providing for a state commission on insanity and substituting diagnosis by the commission for trial by jury.

WISCONSIN

District Society Meeting.—At the annual meeting of the 9th Councilor District Medical Society, held in Stevens Point, May 2, Dr. Thos. H. Hay, Stevens Point, was elected president, and Dr. Potter, Marshfield, secretary and treasurer.

Higher Death-Rate.—The Wisconsin State Board of Health, in its quarterly report on vital statistics, says that the mortality rate during the first quarter of 1911 was 13.7 per 1,000 of population, an increase of 1.5 per 1,000 as compared with a similar period of last year; and that this was due chiefly to the prevalence of pneumonia.

Personal.—Dr. John A. Roberts, Portage, was operated on at the Bentley Hospital, May 7, and is reported to be doing well.——Captain James Scott, M. C. N. G. Wis., Appleton, has been ordered to attend the maneuvers at San Antonio.—— Dr. Frank E. Morley has been appointed health officer of Viroqua.——Dr. Frederick W. Bromley, Palmyra, after twenty-eight years of practice, has retired.——Dr. Gustave Bjorkman, Racine, is reported to be critically ill with gangrene of the right foot.

WYOMING

Personal.—Dr. and Mrs. Fred Horton, Newcastle, have started for a trip through the South.——Dr. Norvel H. Baker, Gillette, has been appointed house physician at the Sheridan Hospital, vice Dr. Vanatta, resigned.——Dr. Charles H. McLean, Laramie, is reported to be critically ill with pneumonia in Denver.

GENERAL NEWS

Association of American Physicians.—The Association of American Physicians, at its meeting in Atlantic City, elected Dr. J. George Adami, Montreal, president; Dr. Lewellys F. Barker, Baltimore, vice-president; Dr. George M. Kober, Washington, D. C., secretary; Dr. Solomon Solis-Cohen, Philadelphia, recorder; Dr. J. P. Crozer Griffith, Philadelphia, treasurer; Dr. Francis H. Williams, Boston, councilor; Dr. William S. Thayer, Baltimore, representative on the executive committee of the Congress of American Physicians and Surgeons, and Dr. Theodore C. Janeway, New York City, alternate.

Railway Surgeons Will Meet.—The sixteenth annual session of the Association of Southern Railway Surgeons will be held in Charlotte, May 29-31, under the presidency of Dr. William C. Day, Danville, Va. Dr. John R. Erwin, Charlotte, will deliver the address of welcome, to which Dr. J. Howell Way, Waynesville, will respond.

THE CHILD WELFARE EXHIBIT

A Presentation in New York and Chicago of Factors Influencing Childhood

The Child Welfare Exhibit, which opened in Chicago, May 11, and will continue until May 25, includes the New York Child Welfare Exhibit which was so successful in that city and is supplemented by an enormous amount of local material, which has become available for Chicago through the generosity of Mrs. Cyrus H. McCormick, Jr. Never since the conferences and exhibitions of the World's Fair in 1893 has such a general interest been emphasized in a civic or philanthropic exhibition. The exhibit was referred to editorially last week.

EXPLAINERS

The work of explaining the various features of the exhibit is in the hands of several hundred earnest workers who speak, not only English, but also all the languages used by the poly- glot population of Chicago; and in addition to the explainers most of the sections are in charge of experts in the field which they cover.

DEPARTMENT OF HEALTH

The exhibit of the Department of Health, Chicago, is espe- cially noteworthy. In one of the first booths there is a mechan- ical model to demonstrate how quickly the air is vitiated in a room with closed windows, and how fresh the air remains if the windows are kept open, and this is emphasized by posters and diagrams on the surrounding walls. In the Motherhood Booth the advantage of the breast-fed baby over the child who has a cow or a whole drove of cows for his foster-mother is shown and the cartoon indicates some of the chances of pollu- tion which dairy milk runs in its journey from the farm to the city. Diagrams, charts, models and cartoons innumerable show citizens how they can use or cooperate with the city's machinery in safeguarding the health or relieving the ail- ments of their children, and also trace the effects of physical defects or diseases on the physical and mental development of the child. The matter of communicable diseases of children is treated in the same manner, and maps and charts show the concentration of contagious diseases. The precautions to be taken to minimize infections are set forth and a simple method of disinfecting is demonstrated. A graphic representation of the mortality of children is shown in a mechanical procession of dolls like that of the apostles in the Strasburg clock, in which every fourth doll drops from the line to illustrate that only three out of every four infants grow to maturity. Demon- strations seem to be the slogan of the department. A model demonstrates the danger of the tuberculous cow to children, and there are illustrations of the proper methods of home filtra- tion, pasteurization and modification. The life of the fly is demonstrated and its effects as a disease carrier.

OPEN-AIR SCHOOLS

The open-air schools of Chicago have an interesting exhibit. Illinois, it is said, spends $1,187,000 every year in educating children who die of tuberculosis before they are twenty years of age, and whose lives might have been saved by transformation of the living conditions from unsanitary to sanitary by the substitution of good for poor food, and fresh for foul air. At the open-air schools there is no long confinement at desks for the pupil; there is plenty of rest, plenty of food and an abundance of fresh air. The result of the first year's work of these schools speaks for itself. The children who entered the schools were below grade and brought records of slow progress, trouble with teachers, an irregular attendance; but in the open-air school the child who had been kept from school by illness continued in school, well, and the intractable pupils became good students. An actual school completely furnished is shown in the exhibit, together with the tent used for shelter for the children in stormy weather. The work now being done in two of the public schools points the way to the work which eventually must be undertaken by the Board of Education, backed and supported by public opinion.

THE CONSERVATION OF VISION

An exceedingly interesting exhibit is that prepared under the supervision of a committee of which Dr. Thomas A. Woodruff was chairman on the conservation of vision and, the wording of two of the most interesting charts of this exhibit are here reproduced:

PREVENTION OF BLINDNESS—LEGISLATION NEEDED

A law to compel physicians and midwives to report all cases of red and swollen eyes in the new born to the local boards of health within twelve hours after discovery.

A law requiring local health officers to see that all cases of ophthalmia neonatorum receive adequate treatment.

A law compelling physicians to see that cases of contagious eye diseases are surrounded with prophylactic safeguards against communication.

A law requiring adequate training of midwives and systematic registration and control.

A law compelling manufacturers to install safety appliances to prevent injuries to eyes.

A law prohibiting the indiscriminate use of fireworks.

A law requiring the proper lighting of all public buildings, particularly factories and schools.

A law preventing the manufacture of wood alcohol.

A little care at birth would have saved about 35,000 eyes.

Immediate treatment and proper care would have saved about 21,000 eyes.

Industrial precautions would have saved almost 12,000 eyes.

A sane Fourth of July would have saved over 600 eyes.

Seventy thousand eyes sacrificed through carelessness and ignorance.

Cost in money to society, about $12,000,000 every year.

Of the 89,000 blind individuals in the United States, it is said that at least one in four goes through life "in the dark" because of the ignorance or carelessness of the one who attended him in the first hour and who failed to apply a simple and harmless remedy before the infection in the eyes could begin.

The exhibit also includes the accidents to the eyes, the effects of wood alcohol and tobacco, the effects of light on the eyes—both direct and artificial—and the proper diffusion and softening of artificial light; with general directions for the lighting of rooms and industrial lighting.

The American Association for the Conservation of Vision announces as its purpose the collecting and standardization of existing in formation on all subjects pertaining to the use and care of the eyes; the securing of the investigation of sub- jects on which present information is incomplete or contradic- tory, and the promulgating of knowledge relating to the con- servation of vision.

THE HEALTH ALPHABET

In the tuberculosis exhibit is a health alphabet prepared by a Chicago tuberculosis nurse, which is of sufficient value to reproduce.

HEALTH ALPHABET

A is for ADENOIDS which no child should own
B for right BREATHING to give the lungs tone
C is for COUGH which we should not neglect
D for the DENTIST who finds tooth defect
E is for EVILS of foul air and dirt
F is for FRESH AIR—too much cannot hurt
G is for GARDENS where boys and girls play
H is for HARDINESS gained in that way
I is for INFECTION from foul drinking-cups
J is for JOY in the bubbling taps
K is for KNOWLEDGE of rules of good health
L is for LUNGS whose soundness is wealth
M is for MILK, it must be quite pure
N is for NURSES, your health to insure
O is for OXYGEN, not found in a crowd
P is for PENCILS—in mouths not allowed
Q is for QUIET, which sick people need
R is for REST—as part of our creed
S is for SUNSHINE to drive germs away
T is for TOOTH BRUSH used three times a day
U is for USEFUL health rules in the school
V is the VALUE of learning these rules
W is WORRY, which always does harm
X is 'XCESS—indulge in no form
Y is for YOUTH, the time to grow strong
Z is for ZEST—help the good work along

In this exhibit is shown a tuberculosis map of Chicago, which shows that of the 3,948 children examined, 760 were suffering from pulmonary tuberculosis and 365 from tuberculosis of other portions of the body. In all, about one-third of the number examined—and these were not selected cases—were suffering from some form of the disease. There are also charts, illustrations and diagrams showing the work accomplished at the sanatoria of the Chicago Tuberculosis Association, illustrations of the outdoor sleeping porch and tent, the diet, kitchen, the milk laboratory, etc.

THE VISITING NURSES

The Visiting Nurses' Association shows its activity in child welfare work by its interesting exhibit. The association has the peculiar ambition and desire to work itself out of existence; so to improve conditions that there will be no need for its services, but, at the present time, not only has this not been accomplished, but the necessity for the use of more nurses has increased disproportionately with the supply of nurses to be obtained. An extensive series of photographs shows the work that is being done daily by the visiting nurses for the children of the poor. The nurse not only teaches the mother how to care for her child, but how properly to prepare food, and emphasizes by precept and example the necessity of cleanliness of person and surroundings.

CONFERENCES AND ENTERTAINMENTS

In addition to the exhibits daily conferences and entertainments are held in the conference room in the annex, in an adjoining church (Grace) and in the main court of the Coliseum. Demonstrations for parents, teachers and others to whom the custody of the child is entrusted form an important part of the conference programs. In a second group of conferences, experts in various lines of child service daily discuss the problems connected with their work and the direction in which an advance is most needed, such as social hygiene, the further development of juvenile court work, the better classification of children with reference to mental and physical defects, better cooperation between parents and teachers, the treatment of dependent, truant and delinquent children, and the better organization of recreational facilities. The third group of conferences is addressed by those who can best interpret the claims of child-life and child-care to the interest, support and service of the whole city. On the main floor of the Coliseum daily entertainments of various kinds, as musical, athletic, apparatus work, plays, etc., are given daily by children of all ages. The results of such an exhibit must be far-reaching and will make for a better and healthier childhood.

FOREIGN NEWS

International Sanitary Conference.—The United States Department of State has been recently advised by the French government that the International Sanitary Conference called by that government to meet in Paris May 26, has been postponed until Oct. 10, 1911. The object of this conference is stated in the invitation to be to revise, to amend and, should the occasion arise, to complete the Sanitary Convention of Dec. 3, 1903, as to the measures to be applied by the powers participating in the conference to control the spread of plague, cholera and yellow fever. It is probable that among the amendments which will be adopted at this conference will be additional articles relating to yellow fever, closely corresponding with those adopted by the Second General International Sanitary Convention of the American Republics, Washington, Oct. 14, 1905. The representatives on the part of the United States who have been designated to attend this conference are Lt. Colonel J. R. Kean, Medical Corps, U. S. Army; Surgeon J. C. Pryor, U. S. Navy, and Surgeon Henry D. Geddings, U. S. Public Health and Marine-Hospital Service.

CANADA

McGill Alumni Reunion.—There will be a reunion of the graduates of the medical department of McGill University, Montreal, in that city June 5-6, just before the meeting of the Canadian Medical Association.

Academy Meeting.—The fourth annual meeting of the Toronto Academy of Medicine and the first to be held in its new home in Queen's Park, was held May 3, and the following fellows were elected to office: President, Dr. Newton A. Powell; vice-president, Dr. Richard A. Reeve; past president, Dr. Albert A. Macdonald; honorary secretary, Dr. W. Harley Smith; honorary treasurer, Dr. William A. Young; and chairman of sections-medicine, Dr. Graham Chambers; surgery, Dr. Herbert A. Bruce; pediatrics, Dr. John T. Fotheringham; pathology, Dr. John J. McKenzie; ophthalmology, Dr. Charles Trow, and state medicine, Dr. John S. McCullough.

Personal.—Dr. J. L. Todd, St. Anne, Que., of McGill University, has started for West Africa to study sleeping-sickness. ——About fifty members of the staff of Toronto General Hospital attended a banquet in Toronto, April 9, in honor of Dr. John Nelson Elliott Brown, the retiring general superintendent. A handsome silver salver was presented to Dr. Brown and an illuminated address was read and presented by Dr. David J. G. Wishart.——Dr. Henry Raymond Casgrain, Windsor, has been elected chairman of the liquor license commission for that district.——The council of the Royal Geographical Society of England has awarded to Dr. Wilfred T. Grenfell, St. Anthony, Labrador, the Murchison bequest for the current year in recognition of his contribution to the geographical knowledge of the world.

LONDON LETTER

(From Our Regular Correspondent)

London, May 6, 1911.

A Committee of the British Medical Association for the Investigation of the Treatment of Fractures

About twenty years ago, "collective investigation" was employed by the British Medical Association for the investigation of disease. This consisted in issuing to physicians blanks on some question in need of investigation. These when filled in and returned were handed over to some authority on the subject for collation, and the results were published in the *British Medical Journal*. The project was started with high hopes; it was thought that the collected experiences of many men would do much to advance medical science and furnish results where individual experience had failed. But in spite of a large amount of work, freely and unsparingly done both by physicians and by eminent authorities who collated the observations, the tangible results were insignificant and it is impossible to point to a single discovery of even minor importance made by this method. Even the very term "collective investigation" has fallen out of use. Such a result might have been anticipated. Observations have weight as well as number, and require skill and experience. Where skilled investigators have failed a host of observers not selected for any special aptitude cannot be expected to succeed. All the discoveries of medicine, whether great or small, have been made by individuals working alone or with a few collaborators selected for the purpose. The Hippocratic maxim as to the difficulty of experience has especial application to investigations carried out by many observers. However, the method has been revived by the association. In consequence of a recommendation made by the section of surgery at the last annual meeting on the conclusion of the discussion on the operative treatment of simple fracture, the council has appointed a committee to inquire into the ultimate results obtained in the treatment of simple fractures with, or without, operation. A notice has been published in the *British Medical Journal* requesting the cooperation of surgeons, surgical registrars of hospitals and other practitioners who may be in a position to assist the inquiry to let the committee have access to records of suitable cases. The investigations will be limited to simple fractures of the long bones which have occurred in the five years 1906-1910.

Destruction of Fleas by Exposure to the Sun

In India the prevalence of plague renders the destruction of fleas a serious problem. For the destruction of these pests in travelers' baggage various powders have been tried. Napththalin acted well, but was too slow, requiring six and one-half hours to kill fleas in a closed space and nine hours in the open. It was then determined to ascertain the effect of the heat of the sun. The results are given in a very instructive "Memoir of the Medical and Sanitary Departments of the Government of India," by Capt. J. Cunningham, an army surgeon. In previous experiments it had been found that rags spread on the ground in thin layers were freed from fleas in three hours. In the present investigation the attempt was made to determine the different ways in which fleas behave when clothes are spread on different kinds of ground. Tin trays 4 by 4½ feet, with sides 4 inches high were made. In these were placed cotton carpets (*dhurries*) and a hundred fleas were introduced, half above and half below the carpet. The tray was drawn out into the sun and the behavior of the fleas carefully watched. They were seen to escape from the glare, but after seven minutes all on the surface were killed, and at the end of half an hour also all those beneath the carpet. When carpets were spread on sand the effects were more marked, the sand absorbing the sun's heat faster than the trays. The fleas made no attempt to burrow into the sand and were almost immediately killed. When the carpets were spread on leaves and grass the fleas dived under the grass and got protection from the sun. With carpets spread on hard ground the time necessary for the destruction of all fleas was forty-five minutes; on sand, somewhat less, the temperature being 117 F. under and 118-142 F. on the surface of the carpets. Experiments were also made with the padded cotton quilts, used by the natives, to see if they protected fleas from the sun's heat. In one or two cases the heat did not penetrate the whole thickness of the quilt and some fleas survived, but on turning the quilt over no fleas were found alive after an hour's exposure to the sun; the temperature inside the quilt was found to be 143 F. The following rules have therefore been drawn up for the disinfection of flea-infested clothing by a means which is simple, reliable, and free from expense. The ground must be fully exposed to the sun and devoid of anything that can shelter the fleas, and should be covered with a 3-inch layer of fine sand. The surface temperature of the sand must be at least 120 F. before the clothing is spread. The clothes must be spread evenly in a single layer for one hour, padded articles being turned once or twice. No clothes must be placed within three feet of the edge of the sand (to prevent the fleas from traveling away). The whole area should be fenced in to keep off animals.

PARIS LETTER

(From Our Regular Correspondent)

Paris, May 5, 1911.

The Sense of Direction Among the Blind

During one of the last sessions of the Académie des Sciences, M. Truschel, of Strasburg, read a communication on the sense of direction in the blind. It is known that the blind find their way very easily and that they seem to avoid obstacles as if they had a special sense. Some authors, to explain these phenomena, have assumed a new sense, sometimes called "the sixth sense of the blind." It has even been maintained that obstacles are felt by means of unknown emanations. It appears, from experiments undertaken by M. Truschel, that the blind have actually the ability to perceive obstacles at some distance, but it is not a sixth sense, the sensation being due exclusively to reflection of sound and not being peculiar to the blind exclusively. For instance, when the ground is covered with snow or the floor with a carpet, the blind find the greatest difficulty in orienting themselves. Therefore, they are able to perceive obstacles brought close to them very slowly and silently, only when there is absolute silence in the room. When the head of the blind person is enveloped with paper, cloth, etc., however, the perception persists. Only a large cylinder surrounding the head can suppress the sensation, because it produces the same effect as the approaching object. M. Truschel believes that the organ of these perceptions is the labyrinth, and that the sense of direction which is so highly developed among certain animals may be explained in the same way.

Monument to Dr. Mesny

A committee has been formed to erect a monument to Dr. Gérald Mesny, who died a victim of his devotion at Foudzadian (The Journal, March 18, 1911, p. 826). M. Berteaux, minister of war, has accepted the honorary presidency of the committee. A subscription will be opened at Tien-Tsin, among the residents and the French physicians, the mandarins and the Chinese students of the school of medicine, of which Dr. Mesny was professor.

The Training of Dogs for the Sanitary Service

In a previous letter I mentioned encouraging results obtained in the experimental employment of dogs for the search of the wounded (The Journal, Sept. 17, 1910, p. 1036). The ministry of war has just created at Fontainebleau, near Paris, military kennels for the breeding and training of the sanitary service dog.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, April 27, 1911.

Benzoic Acid and Its Salts as Food Preservatives

The official board of experts (*Wissenschaftliche Deputation für das Medizinalwesen in Preussen*) has presented a report to the Prussian ministry regarding the permissibility of the use of benzoic acid and its salts for the preservation of foods. In this report the investigations made by the United States Department of Agriculture under Wiley are referred to, by which it was shown that benzoic acid produces poisonous effects only in relatively large doses. The board, however, believes it cannot be said with certainty at present that larger doses (to the amount of several grams) will be permanently so harmless to all human beings as the smaller amounts. The experiments of the American scientists were of too short duration and the results subject to such limitations that they cannot be regarded as convincing proofs of the unconditional harmlessness of the acid. Taking into consideration food legislation in other countries, the board comes to the conclusion that the use of benzoic acid and benzoates for the preservation of foods should not be permitted. The danger of harm is most marked with children and weak or sick individuals. A further objection is raised against chemical food preservatives in general, namely, that by their use the care necessary to prevent food from putrefying or molding will be neglected by manufacturers and dealers.

Personal

Professor Moritz of Strasburg has accepted the call as director of the medical clinic of the academy for practical medicine in Cologne.

Professor Leube of Würzburg contemplates resignation from his teaching position at the end of the summer semester on account of his advanced age.

Professor Manz, the ophthalmologist of Freiburg, died April 21, at the age of 78 years. He joined the faculty in 1859 and became director of the eye clinic in 1868. His chief works dealt with the development, malformations and tuberculosis of the eye and with optic neuritis. He retired from active work in 1901.

VIENNA LETTER

(From Our Regular Correspondent)

Vienna, May 1, 1911.

Responsibility of Physicians and Medical Institutes

The problem of medical responsibility has commanded the attention of physicians in a high degree for the last few years, owing to recent lawsuits which have taken place in this country. Especially *x*-ray workers have lately been victims of such actions, and although in all the recent cases the claims have been dismissed, nevertheless the worry and trouble incurred by the doctors were very telling. Surgeons and obstetricians have lately had to fight out such claims, and in one instance a rhinologist was accused of having disfigured a man whose nose assumed a shape not expected by the patient before he submitted to a plastic operation of this organ. Also hospitals have been sued for damages by patients and in one instance the junior house surgeon, who actually was so unfortunate as to be guilty of malpractice, had to pay heavy damages. The consequence of it was that the members of all the hospital staffs refused to work in the government hospitals unless they were insured against liabilities arising out of such occurrences. A special insurance company has been established by physicians for physicians, whose chief object is to protect the profession against such claims. The medical associations have repeatedly admonished their members to be careful in such instances, and that all medical colleagues should be defended against unjust attacks. Furthermore, all hospitals have been warned against operating on a patient without the written consent of the patient, or, in case he be a minor or not fit to judge for himself, without the consent of his responsible friends. Great stress is laid on the qualities of the anesthetist in operations. In this country he must be a duly qualified M.D. Perhaps to these stringent precautions we owe the relative scarcity of deaths under an anesthetic, otherwise a fruitful source of claims for compensation by the relatives. At present nearly all physicians practicing surgery of any kind in this country, and all hospital physicians also, belong to one or another of the insurance companies. The rate of premiums is 25 kronen ($5) for insurance up to the sum of 20,000 kronen ($4,000), with an additional 10 kronen for each further 10,000 kronen insured. The hospitals are insured, not per person especially named, but per number of doctors employed. The medical councils are at present engaged in statistical research of the points in question: the actual damage done to a patient, whether moral or material, and the actual error on the part of the physician or the nurse or other person employed by the physician, as well as the sums claimed for damages and the sums awarded them in court.

Schools for Crippled Children

A number of children have been placed in special institutions lately in this city with an object of studying the possibility of schools for cripples. The idea is to help those children who are defective in one or more organs, excluding the blind, deaf and mute. The experimental classes consist of forty-three boys, of whom thirteen have lost the normal use of the right arm; seven have lost the right, nine the left eye; fourteen are hunchbacks, while nearly all of the latter show also pathologic changes in the extremities. The children are taught as far as possible on equal lines with normal children of the corresponding age, but with special attention to the individual defect. As far as the results obtained already can be judged, teaching begun early will make the child as useful a citizen as any other person. Great stress is laid on teaching of such subjects as will be of use in future in helping the cripple to earn a living.

Marriages

Lucius C. Buckley, M.D., New York City, to Miss Edna Bruner of Sacramento, Cal., at Petchaburi, Siam, March 20.

James Gilbert Howard, M.D., Ozone Park, L. I., to Miss Mabel E. Clarke of Brooklyn, at Newark, N. J., May 11.

Rena May Heilman, M.D., Leechburg, Pa., and Alexander Pitcairn Lindsay of Pittsburg, at Leechburg, April 12.

George Andrew Cathey, M.D., Portland, Ore., to Miss Bertha Anne Kruse of North Bend, Ore., April 28.

Charles M. Steele, M.D., Reno, Nev., to Mrs. Mylo Egan of New York City, in San Francisco, April 28.

Samuel E. Grout, M.D., Birmingham, Ala., to Miss Mary Stewart Wells of Dyersburg, Tenn., May 18.

Frederick R. Williams, M.D., Bisbee, Ariz., to Miss Elizabeth A. Taft of Houston, Tex., April 26.

James Alexander Logan, M.D., Colona, Ill., to Miss Clara Rimbey of Murrayville, Ill., April 24.

Thomas J. Lynch, M.D., St. Joseph, Mo., to Miss Clare O'Connor of Buffalo, N. Y., May 1.

William Wesley Peter, M.D., Toledo, to Eleanor E. Whipple, M.D., of Chicago, May 4.

Lonnie L. Lanier, M.D., Stillmore, Ga., to Miss Marguerite Harper, at Stillmore, May 7.

Rocco Andrew Montani, M.D. to Miss Eustasia Morone, both of Indianapolis, May 3.

Carl H. Meyer, Jr., M.D., to Miss Johanna N. Jurgensen, both of Baltimore, April 25.

Edward L. Heintz, M.D., to Miss Bertha Marie Hansen, both of Chicago, May 4.

Charles Edward Sidwell, M.D., to Miss Ruth Edna Allen, both of Chicago, May 11.

Emil Geist, M.D., Minneapolis, to Miss Augusta Ohage of St. Paul, May 9.

Manney Rice, M.D., to Miss Mabel Smith, both of Columbia, S. C., April 30.

Deaths

Roscoe H. Ritter, M.D. Medical College of Indiana, Indianapolis, 1897; a member of the Indiana State Medical Association; secretary of the Indianapolis Medical Society; pathologist to the Indianapolis City Hospital; professor of pathology in the Indiana Medical College, and chairman of the college curriculum committee; professor of materia medica and therapeutics in the Indiana Dental College; died at his home, May 6, from nephritis, aged 37. The Indianapolis Medical Society and the faculty of the Indiana University of Medicine, at special meetings held May 6, adopted resolutions regarding the death of Dr. Ritter.

William A. Duncan, M.D. Chattanooga (Tenn.) Medical College, 1898; a member of the American Medical Association, and Association of Southern Railway Surgeons; president of the Chattanooga Academy of Medicine and Hamilton County Medical Society in 1910; for one term city physician of Chattanooga, and a member of the staff of the Erlanger Hospital; local surgeon for many of the railways centering in Chattanooga; died at the home of his parents in that city, May 4, from tuberculosis, aged 35.

William Samuel Smith, M.D. University of Southern California, Los Angeles, 1902; for two years assistant surgeon at the Los Angeles County Hospital and then a practitioner of Arizona for three years; a member of the territorial board of examiners of the insane; physician of Yavapai County and superintendent of the county hospital; died at his home in Santa Monica, Cal., February 19, aged 32.

Jasper Tidball, M.D. University of Michigan, Ann Arbor, 1874; Bellevue Hospital Medical College, 1878; a member of the American Medical Association; local surgeon at Grafton, Ill., for the Chicago, Peoria and St. Louis Railway; who gave up practice about two years ago and went to San Diego, Cal.; died at his home in that place, April 25, from pernicious anemia, aged 62.

Thomas C. Longino, M.D. Southern Medical College, Atlanta, Ga., 1895; a member of the Medical Association of Georgia; captain and assistant surgeon of volunteers during the Spanish American War, and thereafter for a time a practitioner of Galveston, Tex.; died at his home in Atlanta, April 28, aged 37.

George Washington Talson, M.D. New York University, New York City, 1860; for several years a member of the staff of St. Francis Hospital, Jersey City, and physician to the Little Sisters of the Poor; died at the home of his sister in Wheeling, W. Va., April 19, from heart disease, aged 70.

Samuel Eccleston Holtzman, M.D. New York University, New York City, 1862; assistant surgeon and surgeon of the Fifty-Eighth Indiana Volunteer Infantry during the Civil War; formerly of Pontiac, Ill., but of late years a resident of Takoma Park, D. C.; was found dead at his summer home in Ocean Grove, N. J., May 8, from heart disease, aged 73.

Charles Magnus Brucker, M.D. Eclectic Medical Institute, Cincinnati, 1882; for one term mayor of Tell City, Ind., and for two terms a member of the common council; president of the local medical board; a member of the local pension board and local surgeon to the Southern Railway; died at his home, May 9, aged 51.

Madison Waldo Leonard, M.D. University of Alabama, Mobile, 1894; of Attala, Ala.; a member of the Medical Association of the State of Alabama; died in that place, April 30, from the effects of a gunshot wound of the head, believed to have been self-inflicted with suicidal intent while despondent, aged 45.

James Huntington Bailey, M.D. University of Vermont, Burlington, 1857; the oldest practitioner of Ticonderoga, N. Y.; surgeon of the Eighth Vermont Volunteer Infantry during the Civil War; died at his home, April 13, from the effects of a fracture of the hip, due to a fall seven months before, aged 77.

John B. Trowbridge, M.D. Rush Medical College, 1882; a member of the American Medical Association; local surgeon at Haywood, Wis., for the Chicago, Milwaukee and St. Paul Railway, and a member of the local board of United States pension examining surgeons; died at his home, in April, aged 60.

William Alfred Trueblood, M.D. University of Alabama, Mobile, 1902; Washington University, St. Louis, 1903; a member of the American Medical Association; formerly of Ottumwa, Ia., and a member of the staff of the Ottumwa Hospital; died in Baker City, Ore., May 1, from pneumonia, aged 37.

James M. Louther, M.D. Philadelphia University of Medicine and Surgery, 1865; one of the oldest practitioners of Somerset County, Pa.; for many years a practitioner of Stoyestown; at one time a member of the State Board of Medical Examiners; died at his home in Somerset, April 25, aged 72.

George W. Hafele, M.D. University of Maryland, Baltimore, 1908; of Baltimore; died at the home of his sister in that city, May 3, from the effects of a gunshot wound of the head, believed to have been self-inflicted with suicidal intent while despondent from over-study, aged 32.

Emanuel T. Rehrig, M.D. Medico-Chirurgical College of Philadelphia, 1907; a member of the American Medical Association; for four years resident physician at the Whitehaven (Pa.) Sanatorium for Tuberculosis; died at the home of his parents in Easton, Pa., April 28, aged 28.

Augustus Alexander Clewell, M.D. University of Louisville, Ky., 1871; a member of the American Medical Association; a Confederate veteran; for thirty years a practitioner of Baltimore; died at his home in that city, April 28, from angina pectoris, aged 65.

Benjamin Kinyon, M.D. University of Michigan, Ann Arbor, 1871; for many years a practitioner of Cincinnatus, Ill.; for eight years a member of the Board of Supervisors; died at the home of his daughter in Wilmette, Ill., April 12, aged 68.

Henry Kunkel, M.D. College of Physicians and Surgeons, Baltimore, 1889; a member of the American Medical Association and American Academy of Medicine; died at his home in Kingston, Pa., April 26, from chronic bronchitis, aged 49.

Henry Jay Brink, M.D. New York University, New York City, 1883; physician of Britt, and Hancock County, Iowa; was found dead in a livery barn in Britt, May 8, after returning from a professional call, from heart disease, aged 51.

Benjamin S. Shaug (license, Iowa, years of practice 1886); a veteran of the Mexican War, and a surgeon throughout the Civil War; for twenty years a practitioner of Eldon, Ia.; died in Ottumwa, April 28, from cerebral hemorrhage, aged 84.

Thomas Callaghan, M.D. Baltimore (Md.) Medical College, 1900; of Smith's Hill, Providence, R. I.; a specialist in obstetrics and diseases of children; died at the East Side Hospital, Providence, May 5, from cerebral hemorrhage, aged 39.

Alexander J. Rogers (license, Westmoreland County, Pa., twenty years of practice, 1881); a veteran of the Civil War; for many years a practitioner of Scottdale; died at the Rogers homestead in Connellsville, April 28, aged 76.

Marquis Greenwald (license, Indiana, 1897); a pioneer practitioner of Auburn, where he had practiced twenty years; died at the home of his daughter in Auburn Junction, April 25, from cerebral hemorrhage, aged 76.

Harry H. Baker, M.D. Chicago Homeopathic Medical College, 1897; of Chicago; for several years a lecturer on materia medica at Hahnemann Medical College; died in Brooklyn, May 13, from heart disease, aged 45.

Emory E. Howard, M.D. University of Vermont, Burlington, 1884; formerly of South Hadley, Mass.; secretary and treasurer of the Florida Open Air Association; died at his home in Sorrento, May 1, aged 60.

Perdelete Hebert, M.D. Bellevue Hospital Medical College, 1898; a member of the American Medical Association; died at his home in Iron Mountain, Mich., April 26, from carcinoma of the stomach, aged 53.

Henry Garrettson Spooner, M.D. Harvard Medical School, 1897; formerly of Boston; first editor of the *American Journal of Urology*; died in the Massachusetts General Hospital, Boston, May 3, aged 39.

John S. Renninger, M.D. Hahnemann Medical College, Chicago, 1881; formerly a member of the Minnesota State Medical Association; died at his home in Marshall, Minn., last month, aged 54.

Selden LaFayette Blake, M.D. *California* Eclectic Medical College, Los Angeles, 1880; of San Francisco; died in the Irving Sanatorium in that city, April 28, from cerebral meningitis, aged 54.

Henry Rossignol, M.D. Medical College of Georgia, Augusta, 1848; surgeon in the Confederate service throughout the Civil War; died at the home of his daughter in Atlanta, Ga., April 25, aged 85.

Andrew F. Hammer, M.D. Hahnemann Medical College, Chicago, 1878; a member of the Illinois State Medical Society; died at his home in Taylorville, May 1, from nephritis, aged 61.

Charles A. Walters, M.D. New York Homeopathic Medical College, New York City, 1878; died suddenly at his home in Brooklyn, May 2, from cerebral hemorrhage, aged 57.

Dyas C. Ellis (license, Missouri, 1883); for fifty years a practitioner of Missouri; a veteran of the Civil War; died at his home in Garden City, April 21, aged 78.

Emmett Eugene Horn, M.D. *College of Physicians and Surgeons*, Chicago, 1906; died at his home in Englewood, Colo., March 14, from tuberculosis, aged 29.

William L. Stephens, M.D. Eclectic Medical Institute, Cincinnati, 1901; formerly of Lenapah, Okla.; died at his home in Idaho, April 1, aged 52.

T. M. Morton (*registration, Oklahoma, act of 1908*); for many years a practitioner of El Paso, Ark.; died at his home in Davis, Ark., April 30.

Leonard Von Stein (license, Ohio, years of practice, 1896); of Upper Sandusky, O.; died in the Wyandot County Infirmary, April 25, aged 81.

William H. Kindleberger, M.D. Indiana Medical College, Indianapolis, 1875; died at his home in Indianapolis, May 2, from neuritis, aged 54.

William H. Yarnall, M.D. Eclectic Medical Institute, Cincinnati, 1865; died at his home in Detroit, May 6, from pneumonia, aged 68.

Jonathan Edward Burford, M.D. *Jefferson Medical College*, 1879; of Patterson, Tex.; died in San Antonio, April 27, aged 55.

George W. Harmon, M.D. Hahnemann Medical College, Philadelphia, 1884; of Newark, N. J.; died in Mena, Ark., April 21.

William Anderson, M.D. Victoria College, Coburg (Ont.) 1858; died recently at his home in Newcastle, Ont., aged 74.

Adolphus T. Keckler, M.D. Physio-Medical College, Cincinnati, 1866; died at his home in Cincinnati, April 22, aged 80.

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY, TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

TUCKER'S ASTHMA SPECIFIC

An Insidiously Dangerous Cocain Mixture

This nostrum is sold by a Dr. Nathan Tucker of Mount Gilead, O., and is applied locally by means of an atomizer. When written to, Dr. Tucker sends a form letter with circulars describing his "system" for the cure of "asthma, hay fever and nasal catarrh." The "treatment," for which $12.50 is asked, consists of an atomizer and 4 ounces of the "cure." This nostrum has been analyzed repeatedly and in each case, so far as we know, cocain has been found in it.

In 1903, Aufrecht examined the stuff and assigned to it the following composition:

Cocain hydrochlorid	1 per cent.
Potassium nitrate	5 per cent.
Glycerin	35 per cent.
Bitter almond water	35 per cent.
Water	25 per cent.
Vegetable extractives (probably from stramonium)	4 per cent.

In common with nostrums of all kinds, its composition seems to change with the whim of the manufacturer, for when Bertram analyzed the preparation in 1905, he reported finding:

Atropin sulphate	1 per cent.
Sodium nitrate	4 per cent.
Vegetable extractives, dissolved in water with some glycerin	0.52 per cent.

Still later O. Anselmino (*Pharmaceutische Centralhalle*, Dec. 6, 1906) reported that one of his analyses disclosed the presence of hydrocyanic (prussic) acid, but that the analyses of another sample did not show the presence of this drug. He also reported finding a nitrite in the first sample examined but no potassium nitrate. The amount of alkaloid found by Anselmino was 1 per cent., the greater part of which was cocain.

In THE JOURNAL, August 4, 1906, Dr. Herman Vickery of Boston, reported that he had had analyses made of this preparation and that 7 grains of cocain hydrochlorid had been found in each ounce of the remedy. In THE JOURNAL, August 28, 1906, Dr. N. P. McGay of Shiloh, O., reported a case of cocain poisoning in a 5-year old child from the use of Tucker's preparation.

The Massachusetts State Board of Health, in its official bulletin for January, 1907, listed Tucker's Asthma Specific among other cocain-containing preparations which are unsalable in that state.

The London *Lancet*, Feb. 29, 1908, reported a case of poisoning following the use of this preparation. The victim was a married woman, age 36, who had been suffering for some time from asthma. The physician who was called just before her death discovered symptoms of cocain poisoning and refused to give a certificate of death. At the inquest it was shown that she had been taking the Tucker preparation for about two years. In the same issue, the *Lancet* stated that the British agent for this nostrum had been prosecuted under the Pharmacy Act for selling a product containing certain poisons (cocain and atropin) without labeling the preparation "poison." Analysis of the asthma cure at that time was said to have shown the presence of 3.6 grains of cocain and 0.91 grain of atropin to the ounce.

In 1910, the United States Department of Agriculture issued "Farmers' Bulletin 393," a twenty-page pamphlet entitled, "Habit-Forming Agents," by Dr. L. F. Kebler, Chief of the Division of Drugs of the Bureau of Chemistry. In this pamphlet the public was warned against using the various nostrums containing habit-forming drugs. Under "Asthma Remedies" the following statement appears regarding Tucker's "cure":

> "An example of the cocain type is 'Tucker's Asthma Specific,' which consists of a solution of cocain and is sold throughout the United States as a result of extensive advertising and personal recommendation. The 'Asthma Specific' consists of a bottle of medicine containing cocain to be used as a spray with an atomizer. The price of the latter is $12.50. Recent investigations showed that the amount of cocain purchased by the promoter of this remedy from a single manufacturing house during four months varied between 256 and 384 ounces a month."

In March, 1911, a physician sent to the Association's laboratory a sample of this nostrum. Analysis indicated once more that cocain was present.

When one considers the prevalence of the cocain habit and the demoralizing and brutalizing effect that this habit has on its victims, the viciousness of the indiscriminate sale of a preparation of this sort becomes evident. While the excuse is made by the exploiter of this dangerous nostrum that the amount of cocain that it contains is very small, every physician knows that the application of drugs to the nasal mucous membrane will produce *constitutional effects* in quantities that would be considered negligible if administered by mouth. It is only necessary to call attention to those cocain habitués, known as "coke-sniffers," to realize the enormous harm that can be done by the taking of cocain in this way. Under the existing federal law, it is impossible to reach the men who engage in this cocain dispensing traffic, unless they make misstatements on the label. It is high time, then, that the various states enact such laws as will make the promiscuous distribution of cocain a penal offense. When this has been done, Nathan Tucker may perforce engage in a business that will be more respectable, if less profitable, than his present occupation.

MAGIC FOOT DRAFTS

An International Rheumatism Cure Fake

This widely advertised humbug is sold as a cure for rheumatism. It emanates from Jackson, Mich., a town that has the unenviable distinction of being the home of a large number of international medical fakes.

F. G. Badgley, is said to be not only president of this company, but also secretary and treasurer of the J. Lawrence Hill consumption cure fraud[1] and president of the Van Vleck pile cure concern; Badgley is also a lawyer. Whether his interest in law is greater than his interest in quackery, we do not know.

H. H. Mallory, is said to be vice-president of the Magic Foot Draft Company, ex-vice-president of the Hill consumption cure fake and vice-president of the Van Vleck pile cure. Mr. Mallory is also an advertising agent.

R. A. Oliver, whose name still appears in connection with the advertisements of this fake, is said to be no longer living although it is understood that his estate still has an interest in the Magic Foot Draft Company. In common with others of the group, Oliver when living was connected with the Hill consumption cure and the Van Vleck pile cure.

The Magic Foot Draft Company is said to have a somewhat extensive printing plant. This may explain the typographic sameness of much of the advertising sent out by the Hill, the Van Vleck and the Magic Foot Draft concerns.

The foot drafts consist of plasters to be applied to the soles of the feet. The plaster mass is in the central portion of the unfinished side of a sort of oilcloth, the margin of which is coated with an adhesive mixture. The ingredients of the plaster mass were investigated by Dr. L. F. Kebler of the Bureau of Chemistry and the results published some time ago[2] in The Journal. Dr. Kebler reported that the composition of the plaster was:

Poke root	30 per cent.
Pine tar	62 per cent.
Cornmeal	8 per cent.

Dr. Kebler reached the following conclusion regarding the value of the Magic Foot Draft: "They possess no curative element whatever, which when absorbed into the blood will neutralize the poisons which are supposed to be the cause of the rheumatism and in this manner effect a cure."

At the same time, Dr. Kebler also called attention to the fact that the Magic Foot Draft Co. sent out pills of methylene-blue under the name, "Magic Regulators." The value of the Magic Regulators was thus described by the company:

> "To prove the action of our Magic Regulators on the kidney, the organs which in rheumatism are always diseased and fail to do their work, allowing the poisonous acids to accumulate and lay the foundation for a long and painful run of rheumatism, watch the color of the urine, voided. If it assumes a light blue or bluish green color you may rest assured that the Magic Regulators are doing their work."

As the urine of every healthy person always "assumes a light blue or bluish-green color," when methylene blue is administered, it is needless to say that the "Regulators" usually did their work!

The Magic Foot Draft concern advertises heavily in Great Britain and for this reason the British Medical Association recently analyzed the plaster mass of the foot drafts. Their chemist reported:

> "The plaster itself weighed about 80 grains and was found to be a mixture of Stockholm tar and the powdered rhizome of white hellebore; determination of their proportions showed the formula to be approximately:
>
> "Powdered white helebore (veratrum viride)..40 per cent.
> "Stockholm tar ....60 per cent.
>
> "No other ingredients could be detected. Estimated cost of ingredients for one pair, 1/6 of a *penny*." (1/3 of a cent.) Selling price, $1.00!

The difference in the findings of the British and American chemists bears out what has been stated many times, namely, that the composition of nostrums can never be relied on. From what has been said, it is evident that Mr. Adams, in his Great American Fraud series, characterized the Magic Foot Drafts correctly when he said: "Affixed to the soles of the feet they are advertised as drawing out the rheumatic poison from the whole system. Of course they might as well be affixed to the barn door, so far as any uric acid extraction is concerned."

Correspondence

The Round-Ligament Operation

To the Editor:—I have read with much interest the letters of Dr. J. Clarence Webster, of Chicago, and Dr. J. M. Baldy, of Philadelphia, in The Journal, A. M. A., April 29, p. 1280, regarding the origin of the so-called Webster or Baldy operation for suspension of the uterus by posterior suture of the round ligaments. This argument is most amusing to one familiar with certain facts, which, with your kind permission, I shall endeavor to set forth herein.

In 1900 and 1901 I held the chair of anatomy and operative surgery in the Post-Graduate Medical School of Chicago. Sometime in the year 1900, Dr. Frank Andrews, of Chicago, told me of an operation for suspension of the uterus that he had then been using for more than ten years. Dr. Andrews' operation consisted of drawing the round ligaments backward through the broad ligaments beneath the Fallopian tubes, and suturing them to each other and to the posterior surface of the uterus, thus suspending the uterus in a sling.

This operation appealed to me, and I taught it to my classes in gynecology, on the cadaver, and in my lectures at the Chicago Post-Graduate Medical School, calling it the Andrews operation. My first opportunity to try this operation on the living individual came in June, 1901. The patient, Mrs. C. M., entered Chicago Hospital (record number 2,584), and was operated on June 18, 1901. Through a median abdominal incision the uterus and appendages were freed from adhesions; the diseased right ovary and tube were removed; an intraligamentous cyst was enucleated from the left broad ligament, and the uterus was suspended by bringing the round ligaments together behind the uterus and suturing them to each other and to the posterior uterine wall. This patient recovered with the usual pain following this procedure, but with the uterus in good position.

I did this operation next on Mrs. E. M., at the Chicago Post-Graduate Hospital, Aug. 13, 1901. My case record shows that I amputated the cervix, curetted, made a median abdominal incision, resected one-quarter of the left ovary, removed the degenerated right ovary, and a right hydrosalpinx, and suspended the uterus by passing both round ligaments through the broad ligaments and suturing them to each other and to the posterior wall of the uterus.

The next patient on whom I performed this operation was Mrs. M. H., sent into Chicago Hospital by Dr. R. C. Cupler, of Chicago. The record number was 2,696; she was operated on Sept. 8, 1901. I was assisted by Drs. R. C. Cupler and Roy M. Wheeler; the anesthetic was administered by Dr. J. G. Chichester. A typical Andrews operation was done, both round ligaments being drawn backward through the broad ligaments and sutured together and to the posterior uterine wall.

While this patient was still in the hospital, Dr. J. Clarence Webster sent a patient into the Chicago Hospital and did a ventral suspension.

---

[1] The exposès of this and similar frauds have been reprinted in the pamphlet "Consumption Cure Fakes," price 6 cents.

[2] Kebler, L. F.: Nostrums and Fraudulent Methods of Exploitation, The Journal A. M. A., Nov. 10 and 17, 1906.

The house surgeon, Dr. J. G. Chichester, took the liberty of talking to Dr. J. Clarence Webster about the Andrews operation on the round ligaments that I had done a few days before.

A few weeks later, viz., Oct. 5, 1901, there appeared in The Journal A. M. A., an article by Dr. J. Clarence Webster descriptive of his new suggestion for uterine suspension, illustrated with very crude drawings. In this paper technic only was discussed, no cases being reported.

I have no comment to make on this coincidence. Frequently like operations are conceived by different men—often by men residing in different localities.

I have no doubt that Dr. Webster, having independently conceived the operation, naturally desired to be the first to publish a description of it.

I do desire to state, however, that Dr. Frank Andrews, of Chicago, is the real pioneer in round ligament suspension and should be so accredited.

Raymond C. Turck, Jacksonville, Fla.

To the Editor:—A good way to settle the Baldy-Webster priority controversy, in my humble opinion, would be for the disputants to shake hands and agree that they have discovered something that wasn't worth finding.

Their operation practically sacrifices the inner strong ends of the round ligament, and puts all the weight and strain on the outer attenuated and weakened ends of the ligament. Their operation has no advantage over Alexander's or one of its modifications in uncomplicated cases, and certainly is not so good as Montgomery's or the old ventral suspension in those cases requiring laparotomy—ventral suspension to be used in postclimacteric cases only of course.

The Baldy-Webster proposition's greatest weakness is the fact that it does not raise the uterus up unless the broad ligament is perforated low enough down to invite postoperative flexion. It simply draws the organ forward and in that respect is not so effective as Alexander's operation.

Let Drs. Baldy and Webster "bury the hatchet" and compromise on the Montgomery modification of Gilliam's operation for retrodeviations demanding surgery, and devote themselves to solving some of the real problems in pelvic diseases.

C. F. English, M.D., Sonora, Cal.

Lectures on Sex Hygiene

To the Editor:—It seems to have been agreed by the various societies of social hygiene in this country that, for the present at least, the best results in the campaign against the social evil can be attained by educating the public, along sanitary rather than moral lines, in matters of sex hygiene. A recent article by W. D. Parkinson in the *Educational Review*, which was commented on editorially by The Journal, pointed out the unwisdom of merely emphasizing the dangers of the venereal diseases, and the advisability of education of a positive or constructive type along these lines. It may be of interest to note that the National Institute of Moral Instruction is now preparing an illustrated lecture which will deal in a general way with the subject of sex hygiene along the lines indicated. A number of the most prominent educators and capitalists in the country are interested in this organization, and an endowment fund of $500,000 is being raised to extend the work. A number of illustrated lectures on various topics have been prepared and are being given in various cities, especially in high schools, academies, etc. These illustrated lessons, consisting of from fifty to one hundred lantern slides and a printed, illustrated text, are sent by express from four local distribution centers, Baltimore, Knoxville, Chicago and Berkeley, Cal., to all parts of the United States for use by teachers, principals and superintendents. The lessons are intended for use during school hours, the teacher delivering the text while the pictures are being shown. The importance of a lecture which would thus visualize the importance of sex hygiene, reaching as it would thousands of young men, can scarcely be overestimated. Mr. Milton Fairchild, the able and energetic director of instruction of the organization, is now engaged in the preparation of such a lecture, which he proposes to entitle "A Gentleman's Treatment of Women." As a tentative outline, he plans to present the subject matter under the following heads: 1. The beast in man. 2. The dangers of promiscuity make it the practice of a fool. 3. The degeneration of self-abuse. 4. The manliness and honor of continence. 5. The practice of self-control. 6. Purity of mind and body a preparation for marriage. 7. The ideal marriage. 8. Eugenics. 9. A gentleman's treatment of women.

Without offering any personal criticisms of this outline, I am presenting it, at the request of Mr. Fairchild, to the readers of The Journal for their criticisms and suggestions, which Mr. Fairchild requests be sent to him directly and which he will appreciate very much. His address is 903 Calvert Building, Baltimore.

Emil Novak, Baltimore,
General Secretary, Maryland Society of Social Hygiene.

Thyroidectin in Exophthalmic Goiter

To the Editor:—Having read with interest the article on "Treatment of Exophthalmic Goiter with Thyroidectin" (The Journal, April 22, p. 1176) I desire to report one case. I realize fully that one case proves nothing, but I desire to contribute one instance to the sum of collective observation.

The patient, Miss H., aged about 35, housekeeper, came for treatment Sept. 1, 1910, presenting a typical case of exophthalmic goiter. The pulse-rate was 140; the neck measured 15 inches in circumference; marked protrusion of the eyes was present, with tremor, heart murmurs, systolic thrill over the thyroid, etc. The thyroid gland was the size of an average hen's egg, central and uniform in shape. The patient was given thyroidectin 5 gr. capsules three a day, one after each meal. This was continued to October 10, about six weeks, with no discoverable improvement in any way. On the suggestion of a brother practitioner, I changed to quinin hydrobromid, 5 gr. three times a day, after meals, and after five months of that medication, with occasional interruption of one week, the results are certainly remarkable. No other treatment was given; no suggestions were made in regard to hygiene or mode of life, and the patient continued about her work as before.

About the middle of March the pulse was 80, and the neck measured 13½ inches, the reduction of 1½ inches in circumference being due to the disappearance of the growth, as only a normal thyroid could then be felt; the tremor had disappeared; there were no heart murmurs, or thrill over the neck, as there was nothing to thrill. The exophthalmos, however, still persists, though it is possibly not so marked as before the beginning of the treatment, and I fear that the condition may be permanent. During each of the one-week intermissions of the quinin hydrobromid, the patient would not be so well, and the pulse-rate would increase; but during the first week after resuming the remedy, there would be a marked improvement, more noticeable than during the weeks of continuous administration.

W. F. Wilson, Lake City, Minn.

President Taft on Beriberi Among the Japanese

To the Editor:—There was a rather important clerical error in the typewritten manuscript furnished you for President Taft's speech before the Medical Club of Philadelphia. [The Journal, May 13, 1911, page 1400, middle of first column.] He said, "I need not go further than to say that twenty-four per cent. of the sick of the Japanese army were afflicted with beriberi during the Russo-Japanese War." The words "sick of the" were omitted in this sentence, just before the word "Japanese." It seems to me the error is so obvious that it will not make any great difference, except to certain literal souls who will perhaps write to inquire about it. I am asked to write you in the name of the White House to make the correction, with the statement that it was a clerical error.

J. R. Kean, Washington, D. C.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RECENT LITERATURE ON BONE-GRAFTING

To the Editor:—Please refer me to recent literature on bone-grafting. I have a patient with a part of the tibia lost and I want to insert a bone if possible. Has this been done with success?

J. F. CLARK, Fairfield, Iowa.

ANSWER.—Bone-grafting, bone-transplantation and bone-transference have been successfully employed in a number of cases for the purpose of supplying defects in the long bones.

Huntington (*Ann. Surg.*, xli, 249) and Codman (*Ann. Surg.*, xlix, 820) both report interesting cases of bone-transference in which the fibula was made to supplant a defect in the tibia.

In the article on "Intrahuman Bone-Grafting" (*Ann. Surg.*, December, 1909) Mac Ewen describes a method of grafting small particles of bone to fill in bone defects.

Magruder writes on "Bone-Grafting and Osteoplasty" (*Washington Med. Ann.*, July, 1910, and in *Surg., Gynec. and Obst.*, August, 1910).

Tomita (*Deutsch. Ztschr. f. Chir.*, xc, 247) mentions several cases of bone-transplantations. In one case he successfully transplanted 12 cm. of bone from a calf to fill in a defect of the tibia in a man and in another case he used the femur of a rabbit. These are successful cases of heteroplasty. Several cases of autoplasty or the transference of pieces of the tibia to fill in a defect in the same bone at another point are also reported.

Heller (*Ergebn. d. Chir. u. Orthop.*, vol. i) reviews the whole subject of transplantation and his article contains a bibliography of recent literature on the subject.

PHYSIOLOGIC ACTION AND THERAPEUTIC USES OF COTTON-SEED OIL

To the Editor:—1. What are the physiologic action and therapeutic uses of cotton-seed oil?

2. What is the average dose, the maximum dose, and how often should the dose be repeated?

3. What are the comparative food values of cotton-seed oil, olive oil, and eggs?

J. A. BURNETT, M.D., Marble City, Okla.

ANSWER.—1. Cotton-seed oil has the action of other fats and fixed oils. It hinders to some extent the secretion of gastric juice, and tends to provoke the regurgitation of bile and pancreatic juice into the stomach. In the intestine it undergoes saponification and if in excess is excreted with the feces rendering the passages softer and of a light color.

Therapeutically it may be used in place of olive oil to restrain hyperacidity, allay irritation, and relieve pain in the intestinal canal.

2. The dose is from a teaspoonful to a tablespoonful or more, given with or after meals.

3. Oils consist practically of pure fat, which yields 9.1 calories per gram. Half an ounce of cotton-seed oil or olive oil would yield approximately 135 calories; either is equivalent to one and one-half eggs.

The Public Service

Medical Department, U. S. Army

Changes for the week ended May 13, 1911.

Snyder, H. McC., lieut., ordered to Fort D. A. Russell, Wyo., for duty on completion of examination for promotion.

Phelan, Henry du R., M.R.C., ordered to Fort Barry, Cal., for duty.

Dickenson, C. F., M.R.C., relieved from duty at Fort Barry, Cal., and ordered to Fort Duchesne, Utah, for duty.

Bayley, Edmund W., M.R.C., ordered to Fort Sill, Okla., for duty.

Holmberg, Carl E., lieut., relieved from Presidio of San Francisco and assigned to duty at Army General Hospital, Fort Bayard, N. Mex.

VanHorn, James B., M.R.C., relieved from further duty in the Philippines division and assigned to duty at Army General Hospital, Fort Bayard, N. Mex.

Kendall, William P., lieut.-col., leave of absence extended one month.

Brown, Ira C., M.R.C., ordered to proceed to Fort Douglas, Ariz., for duty in the field.

Freeman, Charles E., captain, assignment to duty with troops for station at Yosemite National Park, Cal., is revoked, and instead assignment to duty at Army General Hospital, San Francisco.

Richardson, William H., captain, assigned to duty with troops from Presidio of San Francisco for station in Yosemite National Park, Cal.

Bayley, Edmund W., M.R.C., ordered to accompany the 55th Company, C. A. C., from San Francisco to Fort Du Pont, Del., on the completion of this duty to proceed to Fort Sill, Okla., for station.

Miller, R. M., captain, granted thirty days' leave of absence.

Long, Charles J., D.S., granted thirty days' leave of absence.

Purnell, H. S., captain, relieved from duty at the Army General Hospital, San Francisco, and ordered to Madison Barracks, New York, for duty.

Medical Corps, U. S. Navy

Changes during the week ended May 13, 1911.

Butler, S. St. J., surgeon, detached from the naval medical school, Washington, D. C., and ordered to the Asiatic station.

Zalesky, W. J., P. A. surgeon, detached from the *Salem* and granted sick leave for two months.

Wheeler, L. H., P. A. surgeon, detached from the *Virginia* and ordered to the *Salem*.

Halsey, W. H., asst.-surgeon, detached from the naval medical school, Washington, D. C., and ordered to the *Virginia*.

Ames, M. H., P. A. surgeon, detached from the *Albany* and ordered to the *Helena*.

Dessez, P. T., P. A. surgeon, detached from the *Helena* and ordered home.

Higgins, S. L., P. A. surgeon, detached from the naval hospital, Yokohama, Japan, and ordered home.

Thomas, G. E., asst.-surgeon, detached from the *Saratoga* and ordered to the naval hospital, Yokohama, Japan.

Ohnesorg, K., surgeon, ordered to the Navy Yard, New York.

May, H. A., P. A. surgeon, detached from the naval hospital, Las Animas, Colo., and ordered to duty at the naval medical school hospital, Washington, D. C.

Holloway, J. H., P. A. surgeon, detached from the naval hospital, New York, and ordered to duty and treatment at the naval hospital, Las Animas, Colo.

Woodland, E. E., A. A. surgeon, detached from the naval medical school, Washington, D. C., and ordered to the *Iowa*.

Dickinson, D., Jr., A. A. surgeon, ordered to the marine recruiting station, Cincinnati.

Kindleberger, C. P., surgeon, detached from the navy yard, Mare Island, Cal., and ordered to the naval station, Guam, M. I.

U. S. Public Health and Marine-Hospital Service

Changes for the seven days ended May 10, 1911.

Carter, H. R., surgeon, directed to proceed to Cairo, Ill., on special temporary duty.

Banks, C. E., surgeon, granted ten days' leave of absence from May 10, 1911.

Carmichael, D. A., surgeon, granted fourteen days' leave of absence from May 26, 1911.

Williams, L. L., surgeon, directed to proceed to Vineyard Haven, Mass., on special temporary duty.

Geddings, H. D., surgeon, granted one month's leave of absence on account of sickness.

Brown, B. W., surgeon, leave of absence for one month on being relieved by Surgeon F. W. Mead amended to read "nine days from Dec. 6, 1910."

Lumsden, L. L., P. A. surgeon, detailed to attend the annual meeting of the Ohio State Medical Association at Cleveland, Ohio, May 8 to 11, 1911.

Billings, W. C., P. A. surgeon, granted seven days' leave of absence from April 8, 1911, under paragraph 191, Service Regulations.

Salmon, T. W., P. A. surgeon, leave of absence for two months and ten days from Feb. 8, 1911, amended to read "one month and twenty-three days from Feb. 8, 1911, and seventeen days from April 1, 1911, on account of sickness."

Ashford, F. A., P. A. surgeon, granted seven days' leave of absence from April 12, 1911, under paragraph 191, Service Regulations.

Kaplan, M. I., A. A. surgeon, granted seven days' leave of absence from April 12, 1911, under paragraph 210, Service Regulations.

Moorer, M. P., A. A. surgeon, leave of absence for ten days from March 28, 1911, amended to read "twenty-four days from March 28, 1911, on account of sickness."

Porter, Joseph Y., Jr., A. A. surgeon, granted eight months' leave of absence from May 1, 1911, without pay.

Torres, J. F., A. A. surgeon, granted thirty days' leave of absence from May 22, 1911, with pay, and five months' from June 22, 1911, without pay.

Bowie, R. I., sanitary inspector, died at Nagasaki, Japan, April 24, 1911.

Board of medical officers convened to meet at the bureau, May 22, 1911, for the examination of candidates for admission to the service. Detail for the board: Surgeon R. M. Woodward, chairman; Surgeon J. O. Cobb; Passed Assistant-Surgeon W. C. Rucker, recorder.

Strangulated Hernia.—B. B. Davis, in the *Western Medical Review*, emphasizes the following points: (1) decrease of the number of candidates for strangulation by a more general employment of operations for radical cure; (2) operation in all cases in which the hernia is not well retained by trusses, or in which it is otherwise unusually liable to become strangulated; (3) condemnation of prolonged or harsh methods of employing taxis; (4) immediate operation in every case of strangulated hernia that is not quickly reduced by gentle taxis; (5) in cases of gangrene of bowel in the late cases the superiority of resection rather than any of the make-shift procedures so uniformly unsuccessful.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

DELAWARE: State Society and Homeopathic, Dover and Wilmington, June 20. Secretary of the Medical Council, Dr. H. W. Briggs, Wilmington.

ILLINOIS: Coliseum Annex, Chicago, June 13-15. Sec., Dr. James A. Egan, Springfield.

IOWA: Capitol Bldg., Des Moines, June 5-7. Sec., Dr. Guilford H. Sumner.

KANSAS: Hotel Grund, Kansas City, June 13. Sec., Dr. H. A. Dykes, Lebanon.

KENTUCKY: The Armory, Louisville, May 31. Sec., Dr. J. N. McCormack, Bowling Green.

MARYLAND: 1211 Cathedral St., Baltimore, June 20. Sec., Dr. J. McPherson Scott, Hagerstown.

MICHIGAN: University Bldg., Ann Arbor, June 13. Sec., Dr. B. D. Harison, 504 Washington Arcade, Detroit.

MINNESOTA: State University, Minneapolis, June 20. Sec., Dr. W. S. Fullerton, 214 American National Bank Bldg., St. Paul.

MISSOURI: Gymnasium of St. Louis University, St. Louis, June 12-14. Sec., Dr. Frank B. Hiller, State House, Jefferson City.

NEBRASKA: State House, Senate Chamber, Lincoln, May 24. Sec., Dr. E. Arthur Carr, 141 S. 12th Street

NEW JERSEY: Capitol Bldg., Trenton, June 20-21. Sec., Dr. H. G. Norton.

NEW YORK: May 23-26 and June 27-30. Mr. Harlan H. Horner, Chief of Examinations Division, Department of Education, Albany.

NORTH CAROLINA: Charlotte, June 14. Sec., Dr. Benjamin K. Hays, Oxford.

OHIO: Columbus, June 6-8. Sec., Dr. George H. Matson, State House.

PENNSYLVANIA: Regular, Homeopathic and Eclectic, Philadelphia and Pittsburg, June 27-30. Secretary of the Medical Council, Mr. Nathan C. Schaeffer, Harrisburg.

SOUTH CAROLINA: State House, Columbia, June 13. Sec., Dr. A. Earle Boozer.

TEXAS: Austin, June 27-29. Sec., Dr. J. D. Mitchell, Fort Worth.

VIRGINIA: Richmond, June 20-23. Sec., Dr. R. S. Martin, Stuart.

WISCONSIN: Milwaukee, May 24-26. Sec., Dr. John M. Beffel, 3200 Clybourn St., Milwaukee.

WYOMING: University of Wyoming, Laramie, June 6-8. Sec., Dr. J. B. Tyrrell.

Ohio January Reciprocity Report

Dr. George H. Matson, secretary of the Ohio State Medical Board, reports that at the meeting held Jan. 3, 1911, fifteen candidates were licensed through reciprocity. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Rush Medical College	(1909)	Illinois
Indiana University	(1910)	Indiana
Tufts College Medical School	(1906)	Maine
Harvard University Medical School	(1906)	New York
College of Physicians and Surgeons, Baltimore	(1910)	W. Virginia
University of Michigan, Department of Medicine and Surgery	(1889) (1906) (1909) (1910)	Michigan
University and Bellevue Hospital Medical College	(1910)	New York
Long Island College Hospital	(1909)	New York
Eclectic Medical College, Cincinnati	(1909)	W. Virginia
Western Reserve University	(1886)	W. Virginia
Laura Memorial Woman's Medical College	(1897)	Michigan
Woman's Medical College of Pennsylvania	(1909)	New Jersey

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POSTGRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

POSTGRADUATE COURSE FOR COUNTY SOCIETIES

DR. JOHN H. BLACKBURN, DIRECTOR
BOWLING GREEN, KENTUCKY

[The Director will be glad to furnish further information and literature to any county society desiring to take up the course.]

Tenth Month—Fourth Weekly Meeting

WOUNDS AND THEIR MEDICOLEGAL RELATIONS

INCISED WOUNDS: Appearances, depth, length, direction, shape. Value as indicator of weapon used.

CONTUSED WOUNDS: Appearances, color changes, character of weapon, degree of force or violence. Relation of local lesion to injury to deeper structures; fractures, ruptured viscera.

PUNCTURED WOUNDS: Character of weapon; size, shape, direction, depth of wounds. Injury to deep structures.

GUN-SHOT AND PISTOL-SHOT WOUNDS: Wound of entrance, shape, size, edges, discoloration, powder burns; variations due to shape and momentum of missile, distance, angle of incidence, and tissues injured. Injury to tissues in track of missile. Injury to muscle, fascia, bones, etc. Deflection of bullet. Foreign substances in tissues. Wound of exit, shape, size, relation to wound of entrance.

LACERATED WOUNDS: Character of weapon or injury. Appearances.

HOMICIDAL, SUICIDAL AND ACCIDENTAL WOUNDS: Situation, usual site in suicide. Nature of wounds, extent and number, direction of wound. Bearing of sex. Position of body. Environment.

DISTINCTION BETWEEN ANTE-MORTEM AND POST-MORTEM WOUNDS: 1. Evidences of free bleeding. 2. Clotted blood about edges of wound, and infiltration of surrounding tissues. 3. Retraction of edges. 4. Swelling and injection of edges. 5. Retraction of sides of wound under skin. Differences in incised, punctured, lacerated, contused and gunshot wounds.

Monthly Meeting

Pistol-Shot Wounds in Their Medicolegal Relations.
Infanticide; Evidences of Live Birth; Cause and Manner of Death.
The Legal Status of the Medical Expert in This State.

NOTE: This completes the course as outlined for the year.

Book Notices

A SYSTEM OF OPHTHALMIC OPERATIONS. Being a Complete Treatise on the Operative Conduct of Ocular Diseases and Some Extraocular Conditions Causing Eye Symptoms. Edited and Partly Written by Casey A. Wood, M.D., C.M., D.C.L., Late Professor of Ophthalmology and Head of the Department, Northwestern University Medical School. Complete in Two Volumes. Volumes I and II. Cloth. Price, $15. Pp. 1824, with 968 illustrations. Chicago: Cleveland Press, 1911.

The extent and comprehensiveness of this work may be realized from the fact that the two large volumes aggregate 1830 pages, and that its composite authorship comprises thirty collaborators. These collaborators include the most distinguished practitioners and authors, and the subjects have been assigned to them so that the whole list of surgical diseases and operations on the eye is covered.

In addition to the chapters on purely technical subjects there is a short chapter on the history of ophthalmic surgery by Mortimer Frank, with brief biographical sketches of the originators of operations in this branch of surgery and of men prominent in the development of ophthalmology. There is also a rather exhaustive chapter on the forensic relations of ophthalmic surgery by Thomas Hall Shastid. Both of these are apropos in a work of this character and are well done by their respective authors.

In a brief review of a book containing the work of so many distinguished ophthalmologists it would be impossible even to mention the excellencies of the work of each; so that with no desire to make invidious distinctions we may comment on certain features of the book. The chapters on minor ophthalmic surgery, the extraction of senile cataract, operations on the retina and orbital operations, by the editor, Dr. Casey Wood, are admirable. The first mentioned chapter at once expands the usefulness of the work beyond the limit of the skilled ophthalmic surgeon and furnishes much information of the greatest value to the general practitioner who must, perforce, treat many minor ophthalmic conditions.

The chapter on the surgery of the ocular muscles by Jackson should afford a feeling of satisfaction to the surgeon. Jackson speaks with the authority of experience, knowledge and judgment in presenting his own views, and at the same time does not slight the work nor the opinions of others.

Cataract, always one of the most important subjects with which the eye surgeon has to deal, is fully covered by Casey Wood, D. W. Greene, Peter Callan and Myles Standish, Greene furnishing a chapter on the intracapsular operation according to the Smith method, maintaining with force that while it may have its shortcomings, as do most other cataract operations, it is entitled to a distinct place in the surgery of cataract. The two chapters by Frank Brawley and A. E. Halstead, the first on the surgery of the sinus conditions affecting the eye, and the other on the surgery of other collateral conditions influencing vision, as pituitary and other brain tumors, or conditions requiring decompression operations, are features of great value. The editor has thus wisely recognized the fact that the limits between general and ophthalmic surgery have, during the past few years, become more and more narrow.

The general plan of the work is the same as that followed in the "System of Ophthalmic Therapeutics," the two volumes before us serving as a supplement to it, and the three comprising a complete system of ocular treatment.

The illustrations are a distinguishing feature of this book, and of themselves raise the work into the ranks of *éditions de luxe*. It can be said without fear of contradiction, that no work on ophthalmic surgery rivals it in this particular. The pictures are almost all original, and effectively assist in elucidating the text.

The editor and also the ophthalmologists of this country are to be congratulated on the completion of this great work. It has its imperfections and errors, but they are few and unimportant as compared with the thoroughness, care and scientific exactness maintained by most of the chapters. This system should be in the possession of every English-speaking ophthalmic surgeon.

Case Histories in Pediatrics. A Collection of Histories of Actual Patients Selected to Illustrate the Diagnosis, Prognosis and Treatment of the Most Important Diseases of Infancy and Childhood. By John L. Morse, A.M., M.D., Assistant Professor of *Pediatrics, Harvard Medical School. Cloth. Price, $3. Pp. 314,* with illustrations. Boston: W. M. Leonard, 1911.

In this book the author presents the case histories of 100 actual pediatric cases from his practice, which cover fairly completely all the important diseases of children. These cases are classified systematically, as in any text-book, in the table of contents, for easy reference. In the text the history and physical examination are given first, and the diagnosis follows in heavy type after the clinical evidence is weighed. The prognosis and treatment follow. The reader can thus take up each case as a new patient that presents himself for diagnosis without knowing the diagnosis in advance. This method of teaching from case histories has been in use at Harvard for ten years and commends itself to Morse as "almost as valuable as the clinical lecture in which the patient is shown," and as "surpassed only by bedside instruction to small groups of students." His favorable experience with this method of teaching both graduates and undergraduates has led him to feel that "there was need for the utilization of this method for the presentation of the subject of pediatrics to the practitioner." The book is written in Dr. Morse's well-known direct and vigorous style and makes interesting and profitable reading to any one interested in the diseases of children.

History of the Mississippi State Medical Association. With Biographies of its Presidents, Complete Roster of its Officers, Programs of its Meetings, and the Past and Present Laws Relating to the Practice of Medicine in Mississippi. Cloth. Pp. 171. Dr. E. F. Howard, Secretary, 506 First National Bank Building, Vicksburg, Miss., 1910.

This book was written because the secretary of the Mississippi State Medical Association when he entered on the duties of the office found "an entire absence of records." "There was not even a file of the official transactions, due to the fact that at least twice the secretary's office had been wiped out by fire." Finding it impossible for the Mississippi State Medical Association to obtain a complete set of transactions, Dr. Howard undertook to abstract the items that appeared to him to be of particular interest from copies which he was able to borrow. These abstracts have been made the basis of this history. Along with the history of the association are the other documents named in the title. Possibly this book will suggest to other state associations the desirability of similar work.

The author acknowledges that the book is by no means complete or perfect. Important events in the society's history must have escaped his knowledge. When the members have offered their constructive criticism, a second edition, revised and *enlarged, might be written.*

The Ninth Year-Book of the National Society for the Study of Education. Part II, The Nurse in Education. By Thomas D. Wood, A.M., M.D., Professor of Physical Education, Teachers College and Columbia University; M. Adelaide Nutting, Professor of Nursing and Health, and of Household Administration, Teachers College, New York City; Isabel M. Stewart, Instructor in Nursing and Health, Teachers College, New York City, and Mary L. Read, B.S. Supplement to the Year-Book on "Health and Education" Discussed at the Indianapolis Meeting of the National Society, Feb. 28, 1910. *Paper. Price, 78 cents. Pp. 76.* The University of Chicago Press, Chicago.

The second part of the Ninth Year-Book of the National Society for the Study of Education deals with the nurse and contains, beside an introduction by Dr. Thomas D. Wood and a valuable bibliography, two papers: one on "The Educational Value of the Nurse in the Public School," by Isabel M. Stewart, and one on "Professional Training of Children's Nurses," by Mary L. Read. The first paper emphasizes a function of the trained nurse which has not been generally considered. The value of the properly trained nurse to the physician, to the hospital and to the patient has been repeatedly discussed, but the educational value of the nurse to the public has been given comparatively little attention. The paper is an opportune one in view of present-day developments along this line.

Principles of Public Health. A Simple Text-Book on Hygiene Presenting the Principles Fundamental to the Conservation of Individual and Community Health. By Thomas D. Tuttle, M.D., Secretary and Executive Officer of the State Board of Health of Montana. Cloth. Price, 50 cents net. Yonkers-on-Hudson, N. Y.: World Book Co., 1910.

This little book is the fourth one of a series issued for use in the public schools. While necessarily elementary, it is so written and illustrated as to interest and instruct the child. The book in the main is excellent, although one might wish that such illustrations as the one on page 64 showing "the effect of cigarette smoking" had been omitted.

Miscellany

CLIPPINGS FROM LAY EXCHANGES

Another Group of These Popular Quotations

MUST HAVE HIT HIM IN THE NECK

"He escaped with a sprained ankle, which is remarkable, as the machine struck him between the lamp and the radiator."—Sibley (Ia.) *Gazette.*

WILL IT ALSO MILK THE COW?

"The V.... Pharmacy . . . has been named as a supply station for antitoxin. . . . The antitoxin will be used in cases of diphtheria, to prevent blindness in newly born babes, for throat cultures and in the examination of blood in typhoid and malarial cases."—Cleveland *Plain Dealer.*

SOUNDS AS THOUGH SHE WOULD MISS WEDNESDAY TOO

"Miss B.... W.... was unable to attend to her school duties Monday and Tuesday on account of an attack of cerebral cusa."—Roundup (Mont.) *Tribune.*

FORTUNATELY HIS LEFT RIB ESCAPED

"While cranking his automobile, T.... C.... sustained what is technically known as a Colles fracture of the right rib."—San Francisco *Chronicle,* Feb. 2, 1911.

NO TROUBLE FOR AN OSTEOPATH

"Dr. C. D. V...., the osteopath . . . witnessed an operation while at Kirksville. The operation consisted in the removal of part of the spinal column of a man who was paralyzed. . . . He came out from the operation all right and the physicians all thought he would get well without any trouble."—Atlantic (Ia.) *Telegraph,* Jan. 5, 1911.

INTERNATIONAL GAS FACTORY

"Dr. W. H. W...., the Philadelphia physician decorated by the Kaiser, was already the one American doctor who enjoys the distinction of having a bacillus named for him. And the Bacillus Welchii is the gas bacillus dwelling in the international track."—Boston *Record*, April 8, 1911.

THE BLIND LEADING THE BLIND

"Dr....., on account of failing eyesight and nervousness, has concluded to abandon dentistry and take up optics. He has already partly completed a college course."—Johnstown (Pa.) *Daily Democrat*.

BROKE HIS KNOB—AND THEY SAY THERE'S NO REMEDY

"Mr. F. P. B.... who was injured . . . by stepping from a moving train, was examined by a specialist in Columbus last Monday; and it was found that the knob, on the end of the bone that worked in the socket at the hip joint, was broken from the bone, and that no operation could remedy the injury." —*Marion County Patriot*, Buena Vista, Ga.

A NEW SYNONYM—SOUNDS ODD, BUT CERTAINLY IS DESCRIPTIVE

"Alice H...., an' English actress, died suddenly of optical goiter at Roosevelt Hospital, New York."—*Dramatic Mirror*.

FANCY COLORED FITS

"Three surgeons were called to prove that he would always be a sufferer from chromatic epilepsy."—Erie (Pa.) paper.

ABERRATIONS

"The cause of death was given as shock and acute lumbar pneumonia following six gunshot wounds."—Chicago *Record-Herald*, Jan. 25, 1911.

"Dr. W. R. M...., is recovering from an operation for rhynophima, or 'big nose,' at the Protestant Hospital."—Cincinnati *Post*, March 7, 1911.

"Mrs. M.... died yesterday of diabetes mylitis."—Worcester (Mass.) *Telegram*.

ODD STATEMENTS IN PREVIOUS HISTORY

Naturally, applicants for life-insurance may be expected to put as good a face as possible on the reports concerning relatives and the causes of their deaths, but they sometimes make rather amusing statements. Some one has collected a few of these which were originally published in the *British Medical Journal*.

> "Mother died in infancy."
>
> "Father went to bed feeling well, and the next morning woke up dead."
>
> "Grandfather died suddenly at the age of 103. Up to this time he bid fair to reach a ripe old age."
>
> "Applicant does not know cause of mother's death, but states that she fully recovered from her last illness."
>
> "Applicant has never been fatally sick."
>
> "Applicant's brother, who was an infant, died when he was a mere child."
>
> "Grandfather died from gunshot wound, caused by an arrow shot by an Indian."
>
> "Applicant's fraternal parents died when he was a child."
>
> "Mother's last illness was caused from chronic rheumatism, but she was cured before death."
>
> "Father died suddenly; nothing serious."

There is a delightful innocence about some of these. Take the last, for example. This has a western flavor, as though the applicant appreciated father's having made little fuss about it. When the time came he simply went, that was all.

Vaccination.—In Manila, during Spanish times, there were so many deaths from small-pox that it was necessary to erect in that city a large temporary hospital for the victims, most of whom died. During the last five years no one who had been successfully vaccinated during the five previous years has died in Manila. No one at all has died there since June, 1909. In large cities, and in localities which are easily accessible, the disease is now mild. Owing to a combination of circumstances vaccination, which was begun twelve years ago by the American sanitary authorities, was suspended in Bagac during a period of nine years. A bad epidemic broke out, but when vaccination was begun again no new cases occurred. The official reports from the islands make a very strong document in support of the benefits of vaccination. By the way, the Republicans put a National Bureau of Health into their platform and then took no interest in the subject. The president was enthusiastic about it for a little while and then apparently forgot it. Will the Democrats, who also put it in their platform, pay a little attention to it next winter? A passenger was standing outside the door of a Pullman sleeper when the porter asked him to come inside. "I thought a platform was meant to stand on." "Oh, no, sah, a platform is meant to get in on."—*Collier's*, April 22.

Medicolegal

Poisoning from Ivy Not "Taking" of Poison, But Death Therefrom is Accidental—Visible Marks

The United States Circuit Court, in Minnesota, says that the insured in the case of Dent vs. Railway Mail Association (183 Fed. R. 840) went with his wife to the outskirts of the city of St. Paul, where he, leaving her, walked into some adjacent woods and there cut a branch of oak and a little stick, which he brought back to her. Within a day or two he called her attention to a discoloration between the fingers of his hand which subsequently turned into an eruption that spread to his arms, neck and chest. This eruption progressed and in the latter part of the month he called on a physician who prescribed for him. His condition grew worse, until his death, which the undisputed evidence showed was caused by poison ivy.

He was insured by the association, but its constitution provided: "Nor shall any benefit be paid where death or disability results from voluntarily inflicted injuries, be the member sane or insane; nor from poison or other injurious matter taken or administered accidentally or otherwise." However, the court is very clearly of the opinion that, when it is considered that the word "taken" is used in connection with the word "administered," and that they are both used in connection with the words "accidental or otherwise," it does not include such a case as this one. It must have been an internal taking, and that taking must be the effect of an act voluntary or involuntary of the person injured.

The court thinks that it would shock the ideas of justice of us all to hold that this policy did not include a death by the bite of a poisonous snake. If anything could be considered an accident, that would be so considered, and there is no reason why this association should not pay for such a loss and should not be willing to do so. The clause quoted was undoubtedly inserted to exclude a case of suicide. It was intended to cover such a case, and exempt the company where death resulted from the taking of the insured's own life by the administration of poison by himself; or perhaps to cover such a case as the one in Wisconsin, in which a dentist administered some poisonous substance to his patient.

The next question was whether the circumstances proved in this case showed an accident, and the court thinks that they did, holding that the taking or catching of this poison by cutting the shrub or bush was an accident, and that it came within the terms of the policy.

Nor does the court think that the association could be relieved by reason of the provision in the policy that, "No benefit or sum whatever shall be payable in any case whatever, unless the accident alone results in producing external marks of injury or violence suffered by the body of the member." This does not say when the visible marks must be produced, and it seems to the court that it must be held that it is complied with if such visible marks appear afterwards, though of course it must be established to the satisfaction of the court or jury that those visible marks were the result of the accident. So, if it was established to the satisfaction of the court or jury that these visible external marks were the result of the injury, the fact that they did not appear instantly was not a defense to the suit on this policy of accident insurance.

Dr. Robert [illegible]

MEDICAL AND CHIRURGICAL FACULTY OF MARYLAND

One Hundred and Thirteenth Annual Meeting, held at Baltimore, April 25-27, 1911

The President, Dr. Franklin B. Smith, Frederick, in the Chair

A list of officers elected was published in The Journal, May 13, p. 1396.

A resolution was adopted providing for the appointment of a committee of five to investigate and report on conditions surrounding the care of inebriates in the state, with the view of obtaining such legislative measures as may seem warranted.

A resolution was adopted reciting that, since the completion of the Panama Canal without serious mortality from epidemic and endemic diseases will be a signal triumph of the appreciation of scientific discoveries in the field of preventive medicine, the opening of the canal should be marked by conspicuous recognition of these and kindred services of preventive medicine in the advancement of human welfare and the reclamation of tropical regions to civilization, and that such recognition may be secured and such an occasion fittingly commemorated by the holding of an international congress of tropical medicine.

The Profession of Medicine and Its Relation to the State

Dr. Franklin B. Smith, Frederick: In matters of public interest, such as health and sanitation, pure food, education and the conservation of mental and physical resources, medical men should lead and dominate the laity. Our practice is too continuously on the individual. It should take a wider range, grasp greater subjects, such as pertain to the protection and elevation of society, subjects embracing the prevention of disease and the best means of overcoming ignorant opposition. The value of experimentation on living man and on the lower animals is so evident that it is incompatible with our ideas of good education and common sense to deny it; but, on the other hand, under the present development of modern civilization, no preventable pain, cruelty or torture to either man or animal can be tolerated. Therefore the sensible—not the fanatic—opponents of vivisection may be met squarely and convinced of its necessity and its benefits, while the reasonable prejudices and fears of humane people may be allayed by such restrictions as will make it a certainty that these experiments are never unnecessarily performed or needlessly painful.

Other professions, educators and workers interested in the welfare of the state must be drawn into their proper relation to us and such mutual cooperation secured as will bring about harmonious but well-rounded and developed schemes of advancement. Organized charity, public and private, education and general economics, all offer more inviting fields of usefulness and glory as specialties for the progressive medical man than the overcrowded ranks of surgery, obstetrics, gynecology and even general practice. The subject of the control of the evils of intemperance by restriction of the manufacture and sale of the so-called intoxicants has been before the public for a long time. Much time, money and energy have been spent by able and earnest men known as prohibitionists, advocates of high license, antisaloon leaguers and pledge enthusiasts. Our profession has never taken the part it should take in this question of vast economic importance. This matter has been treated as a religious or political question, or else as one of morals or economics. While in reality it is all of these, in its more essential aspects it is, above all, a medical question.

In the administration and disbursement of its public charities, however, the state needs counsel more than in any other of its departments. In these matters the members of the medical profession are directly interested both as medical men and as citizens. Public money should be disbursed only for value received. Commissions should be appointed because of the merit and fitness of their members rather than because of their political records and influence. The licensing or chartering of hospitals should be entrusted to this sort of control, with power to prescribe the standard of equipment and service without which they could not lawfully prosecute their work. Our efforts should be for higher standards of attainment for our profession, a more general and more discriminative education of the laity in medical matters, greater influence by means of better men on our state boards, a general standardization secured through organization and through the representatives of our national association, cooperation and agreement leading to uniformity of state legislation, rather than the enactment of national laws.

The annual oration was on "Phylogenetic Association in Relation to Exophthalmic Goiter and Sexual Neurasthenia," by Dr. George W. Crile, Cleveland, Ohio.

The Tonsil Question

Dr. H. E. Peterman, Baltimore: There is much difference of opinion as to the physiology and functions of the tonsils. It is my belief that the tonsils perform an important function in childhood, and I seldom perform a tonsillectomy in children under 6 years of age, unless there is some special condition demanding it. Tonsillectomy should always be classed as a major operation, because it is usually necessary to give a general anesthetic, and also because of the fact that severe hemorrhage is often encountered and in this region is difficult to control. When the patient is an adult and not of the nervous type, it is easier and more satisfactory to perform the operation under local anesthesia. The operation should always be done in a hospital. When a general anesthetic is used, ether should always be chosen, unless there is some special contraindication. The key to the successful enucleation of the gland consists in getting properly started under the capsule or between the capsule and the parts beneath. The dangers of the operation are hemorrhage, injury of the muscular structures surrounding the tonsils and infection of the wound.

Dr. Wilmer Brinton, Baltimore: I am glad that Dr. Peterman does not advocate the wholesale removal of tonsils which is practiced by a good many men, for it is quite certain that there will sooner or later be a reaction against this practice, just as there has been against the indiscriminate removal of ovaries.

Case of Pneumococcus Peritonitis

Dr. Harvey G. Stone, Baltimore: The patient, a female child, 5 years old, had pneumonia two years ago, complicated by acute otitis media. After recovery from the pneumonia the otitis persisted and became chronic, with frequent exacerbations of earache and discharge. On March 30, following an indiscretion of diet on the previous evening, she was seized with sudden severe abdominal pain and vomiting, fever and diarrhea. The fever and pain, which was generally distributed over the abdomen, but most acute over the umbilicus, persisted, as did the diarrhea, in spite of calomel. There was slight symmetrical distention of the abdomen in the lower half. There was no localized tenderness and no masses were felt. On opening the abdomen thick greenish-yellow pus welled out. The pus was odorless. No lesion accountable for the infection could be found. The bacteriologic report of the pus examination showed pneumococci. In spite of the Fowler position, Murphy treatment, etc., the child died the day after the operation. No autopsy was secured.

(To be continued)

MISSISSIPPI STATE MEDICAL ASSOCIATION

Annual Meeting, held at Jackson, April 10, 1911.

(Continued from page 1414)

A Case of Empyema

DR. ROBERT DONALD, Hattiesburg: In this case, the patient, who was a child whose illness in the beginning simulated malaria, was given antimalarial treatment. Later, an incision was made and drainage instituted. On removal of the tube on the ninth day the cavity refilled and drainage was again instituted, with satisfactory results.

DISCUSSION

DR. J. W. BARKSDALE, Winona: I do not think it necessary to insert a very long tube. All that is necessary is that the tube project into the pus cavity.

DR. S. S. CAROTHERS, Duck Hill: How much quinin was given the child? The case may have been a mild one of pneumonia.

DR. J. T. LONGINO, Jonestown: The cause of the trouble is bacterial infection. If a microscopic examination had been made several bacteria would have been found playing a part in this infection. I am very much opposed to attributing the cause to quinin.

Report of a Case of Ophthalmia Neonatorum and a Case of Hereditary Syphilis

DR. I. W. COOPER, Newton, reported a case of ophthalmia neonatorum and one of hereditary syphilis and their treatment as texts for a discourse on the problem presented by venereal diseases and the duty of the medical profession to attempt their prevention.

DISCUSSION

DR. S. A. MAJURE, Dixon: I want to speak on the point of legislating against promiscuous marriage. Young girls, their mothers not thinking of any trouble, have been allowed to marry men who have been loose in their habits. A life of misery follows.

DR. L. C. FEEMSTER, Nettleton: I think that it would have been better to use the argyrol in a 50 per cent. solution. When we first began to use this drug we used only 10 per cent. But now we do not use less than a 25 to 50 per cent. solution.

DR. R. D. SESSIONS, Natchez: I have been very much disappointed in the use of argyrol. I am much better pleased with nitrate of silver and I believe that it will accomplish more than the use of argyrol. It is the duty of the obstetrician to carry argyrol or nitrate of silver with him; 90 per cent. of the blind children in the asylums are there on account of gonorrheal ophthalmia. Let us prevent it.

DR. ROBERT DONALD, Hattiesburg: I generally carry 50 per cent. argyrol. Dr. Sessions has not had success with it in every case. I also make use of a boracic acid solution.

DR. R. S. CURRY, Columbus: A continuous application is necessary and the strength of the solution is not so important as its continuous use. As good a result is obtained with a 10 per cent. solution if it is applied frequently.

DR. I. W. COOPER, Newton: I now use as strong as 50 per cent. solution.

Some Intestinal Parasites of North Mississippi

DR. L. KOHLHEIM, Guntown, has encountered 327 cases of intestinal parasites in North Mississippi in the past four years. These he classified as follows: *Necator americanus* 269, *Ascaris lumbricoides*, 21; *Oxyuris vermicularis*, 15; *Strongyloides intestinalis*, 5; *Hymenolepis nana*, 17. He touched briefly on prophylaxis and treatment and made a strong plea for an educational campaign as the only means of eradicating these pests.

Acid-Fast Bacteria and Some of Their Points of Difference

DR. L. HART, Meridian, described various methods in the differentiation and cultivation of acid-fast bacteria. He contended that the smegma and leprosy bacilli cannot be differentiated by the animal inoculation test.

DISCUSSION

DR. GUSTAV MANN, New Orleans: I can hardly agree with the author that we cannot grow the leprosy bacillus. Professor Duval has shown that leprosy bacilli will grow in ordinary goldfish.

DR. J. G. GAITHER, Oxford: Within the last year series of experiments were conducted in two cities, New York and Philadelphia, I believe, and in one city they used acid-fast bacteria but not in the other. In those which showed the bacteria ordinary running water was used but when distilled water was used no bacteria were found.

DR. H. B. WOOD, Jackson: Rosenberger has been exceedingly careful in his work. I think he is correct. When he and his associates found tubercle bacilli they were using distilled water. They got this distilled water from a demijohn. Rosenberger asserts that he has never seen tubercle bacilli which do not stain.

Microscopic Findings in the Diagnosis of Uncinariasis

DR. W. S. LEATHERS, Oxford: There are various reasons why the hookworm has not been noticed in the South until recent years. Its prevalence is practically universal. From investigations by the Mississippi State Board of Health in fifteen counties and two institutions it is to be inferred that Mississippi has a large proportion of infected inhabitants. Microscopic examination of feces should be a routine procedure in general practice.

The Limitations of a Laboratory

DR. H. B. WOOD, Jackson: A laboratory is a place of consultation and the diagnosis made there should not be considered as obviating the necessity of clinical observation. A negative diagnosis should not be interpreted "non-existent" but "not found." Some causes of failure to diagnose in the laboratory are due to faulty technic.

Pathology of Acute Malarial Infection

DR. C. R. GARRAWAY, Brandon, described the blood changes due to malarial infection and indicated briefly the theories as to the causation of fever in malaria.

DISCUSSION

DR. J. T. LONGINO, Jonestown: The internal organs probably undergo some changes as a result of damage done by malarial parasites, due to pathologic changes of the blood. The collection of all this waste matter in the organs causes anemia and consequently enlargement of these organs.

Physiology of the Thyroid

DR. A. M. HARRELSON, Newton: A perfect secretion of the thyroid is necessary for the proper development of bone and fat, for the proper functioning of the skin and the development of many functions of the body. It is perhaps the best understood of any of the ductless glands.

Cardiac Stimulants

DR. S. A. EGGLESTON, Lexington, has small faith in any cardiac tonics save digitalis and rarely uses any of them except in presence of some absolute contra-indication of that drug. He described the physiologic effects of and indications for digitalis, comparing it, point by point, with the other cardiac stimulants.

DISCUSSION

DR. R. E. HOWARD, Durant: We are not perfect diagnosticians. Various cardiac troubles frequently give the same symptoms. No drug that we have equals digitalis in these cases, but we must be very careful in using digitalis.

A Forgotten Use of Calomel

DR. S. MYERS, Vicksburg, called attention to the diuretic effect of calomel and the almost universal ignoring of this action of the well-known drug by the latest text-books. He gave some case reports showing this effect.

DISCUSSION

Dr. B. H. Booth, Drew: The use of calomel is not forgotten in the Delta. We can always depend on calomel, it is almost magical in its results.

Dr. P. R. Brown, West Point: In my practice I have had no remedy which gives me the same results as calomel. There are some cases in which calomel is the remedy *par excellence.*

Dr. S. Myers, Vicksburg: I know that this remedy is not forgotten in the Delta. It is, however, absolutely forgotten in the teaching in the medical schools. It was with the intention and hope of calling attention to this invaluable drug that I wrote the paper.

Iritis

Dr. M. H. Bell, Vicksburg: In this disease treatment gives a good eye and no treatment frequently results in blindness. Symptoms are severe pain, worse at night, redness of eye, contracted and sluggish pupil, blurred vision and lacrimation. The causes are syphilis, rheumatism, trauma, etc.; in the negro race syphilis causes 80 per cent. of cases. Treatment consists in use of atropin, dionin, Arlt's ointment to forehead, leeches to temple and appropriate general treatment directed to the cause if that can be ascertained.

DISCUSSION

Dr. H. D. Bruns, New Orleans: There are three classes of acute inflammation of the iris with which each of us should be familiar: conjunctivitis, iritis or glaucoma. If it is a case of iritis the pain will be greater than if it is conjunctivitis. The other eye must be well covered. If the person has an equally painful eye with discharge, that is conjunctivitis. If atropin be put to the eye in a mild conjunctivitis it is of no avail.

Dr. W. L. Howard, Greenville: An extremely red eye is an indication of iritis.

Dr. R. E. Howard, Durant: After one makes a diagnosis of iritis it is necessary to decide whether it is caused by syphilis or rheumatism. In the majority of cases it seems to be due to syphilis.

Glaucoma and Its Recognition by the General Practitioner

Dr. Henry Dickson Bruns, New Orleans: Glaucoma is divided into the violently painful, acute type and the simple, non-inflammatory type, with other cases presenting symptoms not wholly of either type. In an acute attack, the patient is alarmed, often awakened by violent pain in the eye, not relieved by the usual domestic remedies. The symptoms are a "raw-meat" red globe, steamy cornea, shallow anterior chamber, dilated pupil, sluggish iris and stony hardness of the eye-ball as compared to the normal eye when tested by fingers applied to the upper lid. The eye will be blind or nearly so. No one who cannot compare tension of two eyes should use atropin in an eye. Fatal mistakes are made in these cases through lack of knowledge and by haste, taking the word of the patient that it is neuralgia or seeing a red eye and concluding that it is iritis. No neuralgia ever made an eye more than slightly pink and an acute iritis does not cause dilatation of the pupil. The family physician is the one who sees these cases at the time that treatment can be beneficial, hence the importance of his making a correct diagnosis. A few hours' delay means hopeless blindness. Though these attacks appear so suddenly in most cases premonitory symptoms have usually passed unnoticed for varying periods. In simple glaucoma the burden lies entirely on the ophthalmologist and at the beginning it will at times be impossible to state definitely that we are dealing with glaucoma until the eye has been under observation for awhile. This type of glaucoma has been found common in the negro race. The treatment is iridectomy and miotics.

DISCUSSION

Dr. R. S. Curry, Columbus: It is important that we recognize the condition early. Atropin is the most dangerous thing for the glaucomatous eye. The dilated pupil and the contracted pupil ought to be sufficient to make us distinguish clearly between iritis and glaucoma. Iridectomy will relieve the pain, and I am very much in favor of this procedure even if the patient is blind. The pain is very acute.

Dr. J. B. Bullitt, Oxford: The general practitioner generally ignores the eye; and the conditions in Mississippi are in some respects unfortunate because there are so few ophthalmologists.

Dr. N. A. McLeod, Brookhaven: I wish to propose a vote of thanks for the paper because I think we all feel indebted to Dr. Bruns.

The motion was seconded and carried.

Dr. H. D. Bruns, New Orleans: It is impossible for any man to say much original about glaucoma. The only point that has any originality about it is the observation relative to the negro being especially liable to glaucoma.

Treatment of Postpartum Hemorrhage

Dr. T. H. Seay, New Hebron: This condition may occur after any labor and many of the predisposing causes may be overcome if treated during pregnancy. Treatment is massage, an intra-uterine douche of acetic-acid solution and packing, combined with such general measures as elevation of the foot of the bed, and ergot hypodermatically.

DISCUSSION

Dr. J. H. Cook, Laurel: I visited a patient who had been under the care of a midwife of much experience, who, however, failed to deliver the placenta. She let the patient die. We should not sit by and let a patient bleed to death in these cases. I believe that strychnin is all right in the after-treatment. I have had success with the use of 1/30 or even 1/60 grain of this drug.

Dr. W. M. Turnage, Marksville: We ought to get rid of midwives in the state of Mississippi.

Dr. T. J. Brown, Grenada: What is the purpose of leaving the placenta in the uterus for thirty minutes? My experience has been that if this were done the patients would all have been dead.

Dr. S. W. Purifoy, Yazoo City: I have seen but one such patient die. I am in favor of delivering the placenta very quickly after birth of the child.

Treatment of Aneurysms

Dr. S. W. Johnston, Vicksburg, reported several cases of aneurysm in which he had operated by the Matas method, the most interesting being one of the abdominal aorta.

DISCUSSION

Dr. L. D. Dickerson, McComb City, told of the pain he got in his fingers using pressure for the cure of aneurysms in his college days.

Dr. J. A. Crisler, Memphis, Tenn.: Let us remember that aneurysms may not pulsate.

Dr. J. G. Gaither, Oxford: I likewise have seen cases in which there was no pulsation.

Dr. W. B. Johnson, Greenville: The smallest and best material for these sutures seems to be Japanese silk.

(To be continued)

MEDICAL SOCIETY OF THE STATE OF NEW YORK

One Hundred and Fifth Annual Meeting, held at Albany, April 18-19, 1911

(Concluded from page 1416)

Significance and Therapy of High Blood-Pressure

Dr. J. F. Rooney, Albany: In summing up, one may say: First, the utility of the vasodilators is conversely apparent with the acuteness of the pathologic condition. Second, eliminative measures, hot air, carbon dioxid baths and catharsis, are of much more marked effect in the toxic group. Third, phlebotomy is of great service in the acute toxic group, accompanied by dilatation of the heart, but has fallen into undeserved disuse. Fourth, blood-pressure determinations alone cannot differentiate between the crises of tabes and intra-abdominal perforations. Fifth, the effect of nitroglycerin is as prolonged as that of any of the nitrite group except erythrol tetranitrate, and that its rapidity of action is as great as any and nearly as great as that of amyl nitrite. Sixth, the use of the aconite group as vasodilators is pharmacologically unfounded, and except in the toxemia of pregnancy with a strong heart muscle should be entirely discontinued.

Hydrotherapeutic Treatment of Chronic Disease of the Heart

Dr. John M. Swan, Watkins: In treatment of chronic diseases of the heart, following the lead of the German and French physicians, particularly those at Nauheim, the value of carbonated brine baths has become a matter of common use. In many hospitals and hydrotherapeutic institutes in the large cities, artificially prepared brines charged with carbon dioxid are used in treatment of cardiac diseases with much benefit. At Glen Springs a natural brine is used in treatment of these diseases. The baths are given on alternate days, so that the complete cure requires six weeks. The carbonated brine baths in suitable cases of cardiac disease produce the following effects: (1) a diminution in the size of the heart; (2) a slowing of the pulse; (3) a slowing of the respiration; (4) reddening of the skin on account of the dilatation of the smaller blood-vessels in the cutis vera; (5) reduction in the size of a congested liver; (6) increased flow of urine. These results are due undoubtedly to the influence of the baths on the cutaneous circulation. The amount of blood in the skin is increased, the blood-vessels of the skin are enlarged in caliber, and as a result the heart is relieved of impediments in satisfying the demand of the circulation, so that the blood-flow is equalized in the viscera.

DISCUSSION

Dr. L. F. Bishop, New York: I am thoroughly convinced of the value of the Nauheim method of treatment with baths, but I hesitate to recommend this method at home without being perfectly sure who is going to give it. I make the latter statement because there are a great many physicians who do not give the treatment in suitable cases. This treatment is not specific; it is the adaptation of a great many different things to bring about a result. In severe cases of arteriosclerosis the carbonic acid gas in the bath is better left out. There is more carbonic acid bath in one artificial bath given by some physician in America than there is in a dozen such baths given at Nauheim.

Dr. H. Schoonmaker, Clifton Springs: The question of prescribing the Nauheim treatment is an important one to the individual. We must select the cases. We must know what the conditions are. I like the term Nauheim method rather than Nauheim baths because the scheme involves much more than the baths. It will be helpful when the actual results of the so-called Nauheim method can be determined irrespective of other treatments, because we have to admit that our patients are under a very careful regimen of rest and diet, etc.

Olive Oil in Postoperative Nausea

Dr. C. R. Hyde, Brooklyn: The use of olive oil to lessen and even control postoperative nausea has not received the attention of surgeons that its success warrants. Just as the patient is beginning to return to consciousness, 2 ounces of ordinary olive oil are administered by mouth from a cup. The patient must be sufficiently out from the ether to understand the command to drink the oil, which is then swallowed without any difficulty. It is of interest to note that after regaining complete consciousness the patient does not even recollect taking the oil. Usually within five minutes after the oil has been given, there is free and copious vomiting, which in the large majority of cases concludes the gastric disturbance. The nurse who gives the oil should be instructed to have at hand a basin and towels, and to remain by the bedside of the patient, as the vomiting which is initiated very soon after the ingestion of the oil is explosive and projectile in character. This precaution is imperative, as some patients will vomit with such a violent expulsive effort as to soil the floor for some distance around the bed. Rarely does a second vomiting attack occur, and within a short time the patient is resting comfortably, so far as the stomach is concerned, and is free from nausea or retching. The method insures a quick, rapid stomach cleansing, usually terminating with this one performance, and should be used as a substitute for gastric lavage on the operating table before the patient is returned to the recovery room or bed.

Surgical Treatment of Exophthalmic Goiter

Dr. Martin B. Tinker, Ithaca: The symptoms of goiter are the symptoms of poisoning, similar to that produced by narcotic poisoning. The excessive secretion acting as a poison is produced by the thyroid. In removing a portion of the thyroid we remove the cause of the trouble. The over-use of tobacco causes tachycardia and weakness of the heart's action, not at all unlike the condition seen in hyperthyroidism. Excessive use of tobacco also causes nervousness, general unrest, tremor, sleeplessness, sometimes nausea, vomiting and diarrhea. The presence of excessive thyroid secretion in the circulation has a similar effect.

No sensible man would consider it logical to treat tobacco heart or tobacco amblyopia and allow his patient to continue the excessive use of tobacco. It is just as logical to treat exophthalmic goiter with drugs without removing the source of the excessive secretion. No one, whether internist or surgeon, is so radical as to suggest operation in all cases. Osler's advice that surgical treatment should be recommended after three months' careful medical treatment, if the patient is not better, if it were generally followed, would save many lives and restore to efficiency many patients who do not die. Operation should certainly be advised before irreparable damage has resulted to important vital organs. The greatest strain comes on the organs of circulation and the nervous system, but almost every important vital organ suffers in advanced cases. With careful preliminary study of the patient to determine how much can be done with safety, dividing the operation into several short stages of two days or even weeks apart, with operation under local anesthesia, or in some cases nitrous oxid anesthesia, the operative risk can be reduced to a minimum. In 150 consecutive operations, without fatality, many of the patients were in extremely bad condition. With three exceptions, every patient who has appeared for operation has been operated on. The three patients who were refused operation all died medical deaths in periods ranging from twenty-four hours to three weeks of the time when they were seen. Dangers of delay and frequency of recurrence of symptoms in serious form were mentioned.

DISCUSSION

Dr. W. W. Skinner, Geneva: I agree with Dr. Tinker with reference to the surgical treatment of these patients, and I hope he will teach what he has set forth in his paper until physicians cease holding these patients in bondage, allowing destructive changes to go on in the body, as has been shown by microscopic sections, until they are absolutely useless members of the community.

Dr. Parker Syms, New York: Hyperthyroidism is the real thing we have to consider, and the question which arises in connection with these patients is whether or not they are being poisoned by the internal secretion. Cases of simple goiter of various forms may become the so-called exophthalmic goiter, that is, at some period in their history there may be hyperthyroidism, and it is then that we have these patients presenting a complex line of symptoms from the initial poisoning. It is a poisoning which varies in degree from the mildest disturbance to the most disastrous results. Degeneration takes place throughout the nervous vascular and muscular systems. The important point is that we should recognize this change when it begins; that we should study our patients carefully long before they require operative treatment. My experience has only been with general anesthesia, and I think it has in these cases so many advantages over the disadvantages of local anesthesia that general anesthesia should not be discarded.

Dr. E. A. Chase, Tarrytown: I have had experience with the Beebe serum, and while it has a beneficent influence over cases of exophthalmic goiter in controlling the symptoms, I cannot say that it has ever cured a patient with this disease.

Dr. A. L. Soresi, New York: The only contra-indication to local anesthesia in the surgical treatment of cases of exophthalmic goiter must be a more difficult technic and the pain the operator inflicts on the patient.

Dr. G. E. Beilby, Albany: No one is radical enough to maintain that every case presenting the symptom-complex, more or less complete, of exophthalmic goiter should be operated on. These patients should be placed under observation for two weeks or two months, and then if the symptoms do not improve, operation of some degree should be performed. I believe that local anesthesia is the most important single factor in lowering the death-rate of operations of these cases.

Dr. E. M. Stanton, Schenectady: There is no more definite, clean-cut anatomic operation in surgery than the incision of one lobe of the thyroid, and under these conditions of simple goiter there should be practically no mortality. Dr. Tinker has shown that under local anesthesia the mortality following operations on cases of exophthalmic goiter is now exceedingly low.

Dr. C H. Hacker, Albany: Excitation is an important etiologic factor and we should avoid it in these cases before and after operation. I see no reason why we should not use general anesthesia in cases of partial thyroidectomy. The results obtained by Ochsner, of Chicago, have convinced me that it is a safe procedure, and in a large series of patients operated on by him, covering a period of two years, there was only one death.

Developmental Defects of the Abdominal Viscera with Their Surgical Significance

Dr. W. F. Campbell, Brooklyn: Observation in 500 necropsies, together with clinical experience, have convinced me that many abnormal conditions of the abdominal viscera heretofore regarded as acquired are due to developmental defects and are rationally explained on this basis. In the course of evolution from the quadruped to the biped the long mesenteries of the former have been shortened and eliminated. In the quadruped the abdominal wall acts as a hammock for the viscera; in the biped it acts as a corset. This should be borne in mind in treating enteroptosis. Enteroptosis, nephroptosis and Lane's kink are developmental defects not due to wearing corsets. In the treatment of enteroptosis abdominal supports should be relegated to their proper place and gymnastics should be used to greater extent. Lane's kink is a factor in intestinal stasis, and simulates chronic appendicitis. It should be corrected by surgical procedure.

Malignant Tumors of the Kidney

Dr. H. Adsit, Buffalo: Hypernephroma occurs in from 91 to 97 per cent. of all kidney tumors; it has been a pathologic puzzle. The weight of evidence is in favor of epithelial origin of these tumors and that they are a malignant development of aberrant adrenal tissue. In serial sections of 241 normal kidneys adrenal rests were found in 7 per cent. These growths are *not infiltrating.* Metastases take place through the veins, seldom through the lymphatics. These tumors vary greatly in rapidity of growth, I have seen them of eleven years' standing; others grow very rapidly. In one case, the tumor weighed 7 pounds at the end of two months. Many cases reported as carcinoma are found to be hypernephromata, or else metastases from a primary cancer elsewhere. It is most frequent between the ages of 40 and 50, although cases have been observed in children.

Auscultation of the Cough

Dr. A. H. Garvin, Ray Brook: Auscultation of the cough offers the best means of diagnosis, and it requires no expensive apparatus or special experience. There are four positions of the cough in respiratory cycle: (1) the cough at the beginning of the inspiration, or at the end of expiration—at this point fleeting râles can be heard, especially in the axillary region; (2) the cough during some phase of inspiration—at this position it gives important information in the advanced stages of tuberculosis; (3) the cough at the zenith of inspiration—this is not to be used, as it obscures the sign; (4) the cough in this position, corresponding to the second position, is during some phase of expiration and frequently reveals abundant râles.

Exophthalmos a Common Symptom of Nephritis

Dr. H. C. Gordinier, Troy: This symptom, in varying degree, is a common sign of chronic nephritis, occurring in nearly one-half of the cases. It is usually associated with hypertension, without enlargement of the thyroid or marked tachycardia. It has been entirely overlooked in text-books, and only within a few years is mentioned in medical literature.

DISCUSSION

Dr. L. F. Bishop, New York: The degree of exophthalmos in Bright's disease varies with the condition of the patient, in that it is more marked when the condition of the patient becomes worse.

The Precancerous Stage

Dr. Parker Syms, New York: A careful analysis of cases of cancer with a careful retrospection will teach us more systematically just what abnormal conditions and lesions are frequently followed by cancer, and in this way we really will arrive at the most practical knowledge of the etiology of cancer. From a knowledge of the cause of a disease to a knowledge of its proper treatment is a comparatively easy step, and if we properly apply the lessons we have learned we shall be able to prevent, and that is far better than to cure, a large proportion of cancers.

Cancer Immunity in Its Present Status

Dr. Harvey Gaylord, Buffalo: A small percentage of animals with primary cancers recover, and this is true in a few instances in human beings. This has led to work on immunity. A certain immunity seems to be conferred by inoculating an animal with a growth from a different species. This immunity it has been found is not directed against the cancer cell, but against the growth; it is entirely independent of the cancer cell. From the spindle-cell sarcoma of a rat it has been possible to filter an agent which will produce tumors. One tumor has been thus produced, but it is not a spindle-cell sarcoma, but chondrosarcoma. Sarcoma has been produced in two animals by injection of warm fluid from a cancer of the omentum in a human being. The immunity obtained is specific. The question of vaccination has again arisen, and six cures by this method were reported at the late convention in Paris. In all probability the field for the employment of vaccination will be very limited. Early cases may be amenable. When tumors begin to retrograde it is necessary to remove as much of them as possible. Rats with small tumors have shown a pseudo-Wassermann reaction or deviation of complement reaction. The cases that show improvement give, in course of time, a Wassermann reaction equal to a marked syphilitic reaction. This reaction is a mark of growing immunity. A blood reaction known as the antitryptic reaction gives good indications of the progress of the case and enables one to tell when metastases are occurring.

Treatment of Intestinal Tuberculosis

Dr. S. G. Gant, New York: The results are much better from modern treatment than from the older methods, and more favorable results were obtained in cases in which the infection involved the superficial mucosa than in the enteroperitoneal form in which the inner and outer coats of the bowel sooner or later become involved. A large proportion of cures are now being effected by improved surgical technic and with comparatively little danger to the patient. Therapeutic measures employed in the treatment of intestinal tuberculosis may be divided into measures for improving the general health, symptomatic treatment, irrigation with ichthyol, balsam of Peru, boric acid or krameria and soda, 0.5 per cent. alternated daily with high injections of olive oil and bismuth to soothe the bowel; topical applications of silver nitrate, 8 per cent., balsam of Peru or ichthyol 20 per cent. Surgical treatment includes appendicostomy and cecostomy. Cecostomy and use of the enterocolonic irrigator provides a certain means of irrigating both the large and the small intestine separately or together.

The Rôle of Physicians in the Prevention of Insanity

Dr. A. W. Ferris, New York: The cooperation of physicians is especially desired in the efforts to inaugurate psychopathic wards or pavilions, maintained as a part of general medical hospitals, where borderland cases are received for care pending commitment or other disposition, where initial temporary treatment may be given, and where decent hospital accommodation will be substituted for the jail and the lockup. It is a matter of common notoriety that many insane persons are put under arrest and are treated as criminals and thrown into jail along with criminals simply because no adequate provision has been made by either city or county authorities for their care pending commitment. Here lies the physician's opportunity and herein is found his duty. Lives are in jeopardy, the happiness of thousands of families is at stake. Prophylaxis through a concerted effort is the only true economy and the only logical agency at this critical period in the history of our commonwealth.

Chronic Appendicitis

Dr. E. M. Stanton, Schenectady, presented a critical study of postoperative end-results, and then drew the following conclusions:

1. In my experience appendiceal dyspepsia has been characterized by symptoms strikingly analogous to the earliest symptoms of acute appendicitis, namely, attacks of epigastric or midabdominal pain or distress, but only rarely accompanied by subjective symptoms, referrable to the region of the appendix. During these attacks the pain or distress is nearly always increased by food intake.
2. Pain confined chiefly to the right lower quadrant and not associated with attacks of epigastric pain and nausea is seldom due to the appendix, and before making a diagnosis of chronic appendicitis in those cases every other possible condition should be excluded.
3. The majority of failures have been in patients complaining of right inguinal pain associated with chronic constipation. At operation these patients have presented an unusually long or dilated cecum, usually accompanied by other evidences of enteroptosis. In the future, a certain proportion of those patients may be cured by some such operation as that advocated by Wilms, but appendectomy alone does not cure.
4. Unless the diagnosis is absolutely certain, the gall-bladder, stomach and right kidney should be explored, and the possibility of a Lane's kink excluded in all patients operated on for chronic appendicitis.

PHILADELPHIA COUNTY MEDICAL SOCIETY

Meeting held March 22, 1911

The President, Dr. C. B. Longenecker, in the Chair

SYMPOSIUM ON THE HOSPITAL DISPENSARY ABUSE PROBLEM IN PHILADELPHIA

Dr. Oscar H. Allis: The problem is so simple that any physician can solve it; yet simple as it is, it has remained the same after many annual discussions before the various medical societies. Considering the subject chiefly from the standpoint of state appropriations—which are made to our medical college hospitals and dispensaries in return for the enormous amount of charitable work they claim to do—and as this dispensary work must necessarily be extended to those who come on foot, it is obviously unjust to appropriate state funds for purposes which mostly concern the city. If the state would take care of the insane, aged and infirm, and the feeble-minded, and leave the various localities to care for the injured and for transient illnesses, the question of hospital dispensary abuse would resolve itself into the care of the very poor and such as really could not compensate the physician for attendance.

Dr. Addinell Hewson: The abuses that occur in hospitals come from a misconception on the part of the public. They feel that because they have paid their taxes they are entitled to receive gratuitous treatment from those connected with hospitals. It seems to me that the remedy must come through the county medical society insisting on investigation of those applying for free treatment. From a personal investigation, I have been surprised to learn the character of many so applying. Some patients had been to Europe several times. Some came to hospitals in carriages but dressed in old clothes, and waited in the dispensary. If investigation were made through some of the bureaus of the city equipped for this work there would be less dispensary abuse and the men living in the neighborhood of the hospitals and not connected with them would have a better opportunity of receiving that to which they are entitled. The institutions themselves ought to be impressed with the idea that as distributors of alms they are guilty of malfeasance in office if they give alms to people unworthy to receive them. I assert that if a patient who is well able to pay for treatment receives such treatment without cost that the managers of the institution are responsible for the wrong distribution of alms in their hands and their action ought to be checked.

Dr. Augustus A. Eshner: By hospital dispensary abuse I understand the availment gratuitously of medical services in a charitable institution by those able to pay. No doubt a certain measure of such abuse exists, but the extent and degree are somewhat difficult of estimation. In its worst form, it represents a desire to obtain something for nothing; or an endeavor on the part of those in modest circumstances to secure without cost special service that otherwise would be a strain on their resources, if not entirely beyond their means. Physicians' fees differ considerably, and the question arises whether a sick person shall have the privilege of selecting for his treatment the physician of special skill, ability or experience whose fee he may not be able to pay or shall be compelled to submit for treatment to a physician of lesser skill, ability and experience whose fee he can afford to pay. Who shall decide whether a patient can afford to pay for medical services or not; and how much he can pay? It would seem that the patient himself is the best judge, and if he is willing to admit his inability he should receive the benefit of any doubt. Naturally there will be some imposition, but it were better that a few guilty should escape exclusion than that one deserving person should be deprived. The dispensary patient who would deceive in this connection would equally find a way to evade payment of the physician's bill he is compelled to incur. From the practical standpoint the simplest solution of the problem would be to address to every applicant for dispensary treatment the question whether he is or is not able to pay a professional fee. If the answer is in the negative he should be received for treatment, if in the affirmative he should be referred to the physician of his selection.

Dr. George Erety Shoemaker: I have had more experience with this problem in connection with the indoor patient. The question of hospital abuse is complicated by the fact that hospitals have changed in scope, while their attitude toward the patients applying has not changed. No longer only the poor go to the hospitals but all classes. Some of the causes of abuse cannot be controlled; others can be corrected by the checking system. The remedy lies in frank recognition of the fact that hospitals are no longer public *charitable* institutions, but that all classes are seeking in them treatment; and, in having paid business officials, whose duty it shall be by investigation to weed out such persons as are of sufficiently good financial standing to pay. These individuals should be referred first to their own physicians and second to the younger men working in minor positions in the hospitals. There should be recognition on the part of all concerned that no one group of people is to blame, but that there are many causes at work. Physicians should not recommend for free beds persons whom they do not know. Often the families are able to pay but are not asked.

DR. J. M. BALDY: In from twenty to twenty-five years in dispensary work in Philadelphia it has been the exception in my experience to find people who were really well able to pay for medical treatment attempting to get something for nothing. A great deal of the dispensary abuse has been due to the physician himself, and to the fact that we live in a teaching center and must have material for teaching. The clinic that uses material in that way is paid in a measure for the so-called abuse. Better abuse than injustice; I would far rather treat a patient who I knew had abused my confidence, than turn away one poor person who needed treatment. The remedy lies with the individual physician. He can ascertain who are worthy without placing the applicants in humiliating positions. There is also a collective way by education of the public to the effect that it puts shame on persons to apply for free treatment if they are able to pay.

DR. JOSEPH D. FARRAR: The abuse of medical charitable service by institutions and the flagrant misuse of this charity for persons and for interests which can have no claim to our free service is such an insult to our self-respect and indignity to our intellect that we are in duty bound to resent it. A stipulated card ought to be filled out for each patient, a carbon copy to be retained by the dispensary, and the card itself sent on the same day to the office of the bureau of investigation, which should be established by the Charity Organization Society. The dispensary should provide itself with the means for the filing of the cards, but the cards themselves should be provided by the bureau of investigation. The original card should be filed with the bureau of investigation; the report of the bureau concerning each patient should be returned to the dispensary in convenient form for filing, with the card for that patient retained by the dispensary at the patient's first visit. Blanks should be filled out, giving name, age, occupation, residence, how long residing there, former address, place of employment, salary, how long in Philadelphia, family physician, physician last consulted. I believe that if we could raise a certain amount in Philadelphia, the Charity Organization Society would be only too glad to establish this bureau of investigation. Chicago is going ahead in this work by subscriptions furnished by physicians.

DR. G. M. ILLMAN: I think, as Dr. Baldy put it, that the trouble is due entirely to the physicians. This is true from many standpoints. Dispensaries are multiplied by the physicians themselves. A physician who has difficulty in getting his patients into the hospitals, becomes disgruntled and opens a house for the treatment of them, and this in time becomes a hospital. Dispensaries are started also by the state for the treatment of special diseases. I believe that the physician who pays state taxes is as much entitled to the facilities of the hospitals in his neighborhood as are the men connected with them. With this idea in mind, I have suggested that it is our duty to cooperate with every man wanting to use the wards of our hospital. In admitting patients for treatment we endeavor first to ascertain the name of their physician, and whether or not the patient is able to pay. We have gotten up a series of letters, one of which is sent to the family physician when the patient is admitted, and another when he is discharged. A similar method is employed in the dispensary. At the top of the dispensary card we have printed: "For the worthy poor." We have found these measures remedial in the question of pauperizing the public.

DR. JOSEPH PRICE: We should recognize the importance of scientific and not political care of worthy charities. Institutions of trust should be used wisely for their specific purposes. The tendency to multiplication of private institutions in the very teeth of old, large, and well-endowed charities emphasizes the fact that there is always something in public charity that snuffs out the scientific and humanitarian spirit and skill that the public demands. I have run a private hospital for more than a quarter of a century. One hundred of my colleagues and intimate friends have done precisely the same thing and attained skill and international prominence for their accomplishments and life-saving efforts. In this state, I have had the opposition of the great commonwealth. In other states such handicap does not prevail. Discrimination should be practiced in all institutions. The family and friends of all employed can easily pay hospital expenses. It would be difficult to determine just what is done with the endowment, the annual donation of the public and the maintenance from the state. One naturally asks what is done with such generous contributions. Private institutions have but one source of revenue and are excessively taxed and assessed.

DR. STEWART C. RUNKLE: There is no question of the existence of hospital dispensary abuse. I believe also that the hospitals and dispensaries are guilty of wrong. Patients are admitted without being asked whether or not they are able to pay. The people who have no business there are the very ones found there day after day, and no effort is made by the attendants to communicate with the family physicians. The little dispensaries, in my opinion, ought to be put out of existence entirely.

DR. HIRAM R. LOUX: Voluntarily, I do not believe that any patient who comes to the dispensary will tell his financial condition. He wants service free of charge if possible. There should be a general bureau of registration in large institutions from which the patients should be distributed to the various departments. No applicant should be treated free who is able to pay his family physician. Then, too, physicians drive patients to the dispensaries by long treatment without results. It is possible that the only effective way to overcome this evil would be through the appointment of a board of charity with sufficient remuneration to pay for the treatment of the poor in institutions.

MR. PORTER R. LEE, General Secretary, Society for Organizing Charity: The chief handicap which the abuse of the free dispensary privilege puts on the work of the Society for Organizing Charity follows from the habit of some of the sick poor going to several different dispensaries at the same time. So far as I have any suggestions to make to-night, I may summarize them as follows:

1. Overlapping in treatment ought to be and can be prevented, by the system of registration which we in cooperation with other city charities have adopted. Each society sends to a registration bureau at stated intervals, preferably every day, either by mail or telephone, a list of the persons who have applied for assistance. In response to this inquiry, the charitable society is given the names of such other charities as have already registered the same persons. The use of geographic areas is another available method of prevention.

2. Investigation of cases is desirable both to expose fraudulent applications and for the more important reason that only so can the dispensary treatment be definitely related to home, industrial and moral conditions which have a bearing.

3. When such investigations reveal conditions requiring relief and special kinds of service for which the hospitals and dispensaries are not equipped, the Society for Organizing Charity will be glad to cooperate in securing it.

4. Social service work as established by several of the Philadelphia hospitals and dispensaries for investigation and social treatment has proved to be a connecting link. The result has been a greatly increased efficiency from our point of view and we have received the testimony of medical men that it is true also from their point of view.

The solution of the problem of dispensary abuse must be largely in the hands of medical men, although it vitally affects the treatment of the poor by charitable societies. Any movement looking to the improvement of work in which we have a common interest will draw our hearty cooperation whenever physicians care to have it.

DR. R. OLIVER KEVIN related a number of incidents illustrative of the deception practiced by persons applying for free treatment at dispensaries. In one instance the patient after receiving treatment directed that a cab be called for her. Another instance was that of a person owning a large number of houses who described how cleverly she dressed up and went to the University of Pennsylvania where she received free treatment.

DR. E. J. G. BEARDSLEY: I have not heard of any hospital trying to stop this evil. I know of only four dispensaries that are actually trying to treat only people who deserve to be treated in the institutions. One is the Henry Phipps dispensary. Before the physician ever sees the patient, the patient is asked what the income of the family is and it is at once decided whether or not the patient is acceptable for treatment. I never saw a patient admitted who seemed to be able to pay. All the dispensaries run by the State of Pennsylvania ask the same question and with the same results. In the Jefferson medical department we send away from fifty to 250 patients a month who are able to pay. The statements of the patients themselves prove that they are perfectly able to pay a physician. We ascertain the name, address and amount of income of the applicant. A large element of the trouble is the fact that many people outside are treated very badly. The patient receives no examination, no diagnosis is made and he is treated in a most indifferent way. Many of these patients tell, without inquiry, such tales that we treat them at once. In one instance a man with a failing heart was told that he needed *x*-ray treatment, and this was given him—at $5 a "throw." The problem is said to be a hard one. If this is true, it is made so by the physician, continued by the physician, and can be readily stopped by the physician. A hospital that accepts money from the state to take care of poor people should see that poor people are treated. I was interested and gratified in overhearing the remarks of two boys waiting in our dispensary. One had said he did not believe he could wait, when the other boy replied: "You will soon see the feathers and the furs come out."

Dr. B. Alexander Randall: The dispensary physician or surgeon has a multiple responsibility: his responsibility to the institution, to his fellow practitioners, to his students, to the public, and to the patient, both as a sick person and as a citizen. Many of the public still believe that the hospital and dispensary are provided by the state for the free use of all citizens, just as the public schools are open to all who are not too snobbish to use them, and that they as taxpayers have a right to the services of all medical men in the dispensaries. Mercenary men may strive to use dispensary positions to fill their own offices. Well-meaning physicians will bring to a dispensary surgeon patients for examination whom they state are to be placed in his care as pay-patients. My services having generally been used for teaching, I have made it a rule to examine each patient so as to meet any urgent needs, to use pointedly for teaching purposes the doubtful patients, and only after we had received that much *quid pro quo*, to register the findings and in especial relation to the address given make inquiry concerning the need of charity treatment. After having been given a realizing sense of what charitable treatment is likely to entail, most of the improper cases are ready to consult a physician in his office. One should never volunteer his own address to any but emergency cases requiring treatment between clinic days. While it is often best that the same worker should keep oversight of a patient at the return visits, the chief may discourage the doubtful patients, who wish to have in the clinic the skill of a certain man only, by assigning them to others. They will inquire the address of the man desired and voluntarily consult him.

Dr. William Duffield Robinson: Of the number of people receiving free dispensary treatment fully 10 per cent. could pay the fee that the young doctor is accustomed to receive from people in moderate circumstances. In New York state it is now a statutory crime for one able to pay to take free dispensary treatment from hospitals receiving state aid.

Dr. G. G. Davis: Among some of the causes of the abuse which exists are the facts that: 1. Physicians are saddled by the public with an unfair proportion of the charitable work in a community. This is shown by the character of the applicants for charitable medical services and by the disapproval which is likely to be visited on a medical officer who refuses applicants his medical services. 2. There is an absence, first, of any standard as to who are unworthy; and, second, of any means of enforcing a standard. 3. By the direct encouragement of the profession, largely due to the expense of apparatus and dressings and to not being qualified in the specialties.

The following remedies are offered: 1. The hospital should maintain an official whose duty it should be to decide as to the claims of the applicant for treatment. It is difficult for the physician in charge to do this. 2. The profession should cease to refer improper cases to the public institutions and should see that the patients have a proper opportunity of securing treatment elsewhere.

Dr. John B. Roberts: I am of the opinion that persons of moderate circumstances frequent the hospital dispensary: 1. Because many family practitioners are not well posted in modern methods of investigating and treating disease, or are too careless or too lazy to give their patients the benefits of scientific treatment. 2. Because those who are competent to treat the sick, particularly in the specialties, ask fees too high to be paid by patients of the middle class, such as artisans, and self-supporting women. I believe that a graduate, who has tact, energy and medical knowledge and who is willing to work hard and well for his patients, need not fear that mechanics and business people of moderate means will prefer the hospital to him as a medical attendant. The man who is treated for weeks for debility by a doctor who never examines his urine, or for bilious headache by one who never asks about his vision, is apt to obtain better treatment at the hospital dispensary than at the hands of an inefficient medical graduate.

Dr. A. B. Hirsh: The statements made here to-night are repetitions of those made in Chicago. The managements of hospitals in Chicago, after acknowledging the abuses, refused to reform their methods. The general practitioners got together and the specialists began to take alarm at the thought of losing valuable consulting practice. The situation was controlled by the general profession paying the expenses of the United Charities in handling the subject. Each dispensary in that city sends each morning to the United Charities a typewritten list of the new patients with their addresses and that body, after going over the catalogue, sends in its report to the institution. We must do that in Philadelphia. Those who expect individual hospitals to do this will be deceived. It must be done by all the hospitals together with the entire medical profession backing up the movement.

Dr. Howard S. Anders: Not many years ago there came to my intimate knowledge the experience of a chief of a medical dispensary who, feeling that loyalty to the profession at large was on a higher plane than loyalty to the institution itself, instructed the attendants to discriminate between those people able to pay and those who were not. After some time this came to the ears of those higher up and he was informed that he must discontinue such discrimination because it would lower the percentage of work done and interfere with a sufficiency of cases for demonstration. This he refused to do and resigned. This is illustrative of one aspect of the question within the medical profession itself and demonstrates institutional vanity for statistics and professorial avidity for cases.

Resolution Adopted

Dr. Howard S. Anders offered the following resolution, which was seconded and carried:

Whereas, the results and trend of the symposium discussion on the topic "The Hospital Dispensary Abuse Problem in Philadelphia," indicate sufficiently its vital importance and general medicosociologic significance as to call for further, broader, and yet more definite and responsible action; be it

Resolved, That a committee of five be appointed to devise ways and means of practically dealing with such abuses as are considered to exist; and to report conclusions and recommendations at the June business meeting of the society.

The following committee was appointed: Dr. Howard S. Anders, chairman; Dr. G. Morton Illman, Dr. Edward J. G. Beardsley, Dr. A. B. Hirsh, Dr. Joseph D. Farrar.

Dr. J. Cardeen Cooper: It does not seem to me that a learned profession should attempt to regulate this matter by appointing a committee. From the general practitioner's standpoint, the abuse does not exist with the hospitals so much as with the general profession. If the committee gives its attention alone to the hospitals the matter is one-sided. As Dr. Roberts has said, people go to hospitals because they receive better treatment, and in many instances they do. Therefore, the matter is in the hands of the general practitioners, and as soon as we become proficient and treat our own patients the hospitals will not make such great inroads on them.

10 Diagnosis of Pellagra. H. F. Harris, Atlanta, Ga.
11 Vaccine Therapy and a Simplified Opsonic Index. A. W. Crane, Kalamazoo, Mich.

1. **Mitral Stenosis.**—It is the authors' conviction, based on careful study of the anatomic relations in hardened preparations, that the indirect mechanism may be a variable one, but that when compression is accountable for the recurrent paralysis it must always be caused by the nerve being squeezed between the left pulmonary artery and the aorta or the aortic ligament. Anything which will dilate or force upward the left auricle, the left upper pulmonary vein, or the left pulmonary artery would tend to cause the condition. The anatomic relations are such that direct pressure of any portion of a dilated left auricle on the aortic arch is impossible. Considering the softness of all the structures involved, and the fact that the nerve is normally flattened against the aorta, not rounded, it would seem that its function is abolished, not from actual destruction from pressure, but from a neuritis consequent on a degree of compression which could hardly be sufficient actually to destroy the vitality of the nerve.

2. **Arneth's Method of Blood Counting.**—The authors endorse Arneth's method as having a distinct value in enabling one to estimate the resisting power, and hence the likelihood of recovery and general prognostic outlook in cases of tuberculosis. Arneth considered that young white cells—those with one or two nuclei—are less resistant and less able to combat an infection than the older ones with more nuclei. Starting out with this assumption, he counted the number of nuclei in all the neutrophilic white cells, and divided them into five classes, according to the number of their nuclei. Placing these numbers in a horizontal row, beginning on the left with Class I, which contained one nucleus, and ending on the right with Class V, which contained five nuclei, he formed what he called the neutrophilic blood-picture. From a count of fifteen normal individuals he formed a normal picture. Studying the blood in pulmonary tuberculosis, he found, in consonance with his theory, that the normal percentage of nuclei in the different classes was lost, there being an increase of the younger cells of Classes I and II, and a lessening of the more mature ones in Classes III, IV and V, this being more marked in proportion to the severity of the trouble.

8. **Gonococcus Infections.**—The complement-fixation test as applied to the detection of gonorrhea by Schwartz and McNeil proved of great assistance. They found that the different strains of the gonococcus differ markedly one from another—so much so that the antibodies produced in the body by the toxin of one strain will in many instances not bind complement in the presence of an antigen prepared from another strain. Therefore, if only one strain is used in the preparation of the antigen, a great many negative results will be obtained in positive cases. An antigen prepared from many strains fixes complement whenever one of its component strains does so and, consequently, the necessity of testing a serum against a number of antigens separately is avoided. It is not to be denied that there probably are other strains of gonococci differing widely from any present in the polyvalent antigen, so that at times a negative result will be obtained in a positive case. They believe, however, that working with an antigen composed of many strains, one will obtain a positive reaction in the majority of cases of gonococcus infection, and the use of the polyvalent antigen simplifies the procedure so that it can be of practical value for diagnostic purposes. The facts seem to prove that a positive reaction is an indication of living gonococci somewhere in the body, and if found in men or women supposedly cured of gonorrheal infection in the genito-urinary tract, should be construed to mean that they are still capable of infecting others through sexual intercourse. The importance of this in connection with marriage is self-evident.

9. **Pulsations in the Peripheral Veins.**—That the right heart may produce a pulse wave in the veins of the extremities is shown by Bailey's observations. This pulse wave occurs considerably later than the arterial pulse. He suggests that incompetency of the tricuspid valve may be the cause of varicosities of the veins of the extremities.

21 *Efficacy of the Ipecac Treatment of Dysentery. E. B. Vedder, U. S. Army.

21. **Ipecac Treatment of Dysentery.**—The results of bacteriologic experiments made by Vedder seem to show that 2 per cent. fluid extract of ipecac inhibits the growth of dysentery bacilli, although this is not a specific action, since ipecac also inhibits the growth of bacteria, and other drugs, such as hydrastis and digitalis are quite as powerful as ipecac in inhibiting dysentery bacilli. The *B. dysenteriæ* of the Shiga type that Vedder worked with appears to be more susceptible to the action of ipecac and other drugs than the Flexner strain. The treatment of bacillary dysentery by ipecac is not recommended by Vedder, because, he says, it has not been shown that ipecac possesses any greater activity against dysentery bacilli than many other drugs, and because it would probably be difficult, on account of dilution with intestinal contents, to give sufficient ipecac to make a solution in the intestine as strong as a 2 per cent. solution of the fluid extract, which was the strength used in these experiments. However, since ipecac has been shown to inhibit the growth of dysentery bacilli to some extent, it has probably done patients with bacillary dysentery no harm and, on the other hand, may possibly have accomplished some good, particularly if the dysentery were caused by the Shiga type of *B. dysenteriæ*.

The experiments showed that the action of ipecac on amebas is much more powerful. Amebas in a 5 per cent. bouillon culture were at all times killed by a fluid extract of ipecac in a dilution of 1/50,000, and sometimes killed by even higher dilutions such as 1/200,000. In these experiments two varieties of amebas were used, one isolated from tap water, and one isolated from the stool of a normal man. Vedder was unable positively to identify either culture, but is sure that neither of these varieties was either *Entameba coli* or *Entameba dysenteriæ*. Vedder holds that the ipecac treatment of dysentery caused by protozoa should not on light grounds be set aside in favor of any other, but that in using this treatment great care should be taken to make sure that the dysentery is truly caused by protozoa and is not bacillary, and also to obtain an ipecac that is shown by actual analysis to contain its proper amount of emetin, and when this is not possible, to insist on obtaining the Brazil root.

34 *Medical Treatment of Ingrowing Toe-Nail. S. Harnsberger, Catlett.

34. **Treatment of Ingrowing Toe-Nail.**—Surgical intervention, which is surgical interference, is not considered a treatment for ingrowing toe-nail by Harnsberger. He believes in local treatment. He cleanses the unhealthy soft parts, using, if necessary, some reliable antiseptic solution or soap, with or without a brush, as the case may be. Then, after drying the cleansed parts thoroughly, he applies liquefied phenol (one drop usually) to the most sensitive point and as near the corner of the nail as he can get it. If the toe is well protected by clean gauze, the phenol is used once a day, with or without recleansing, until the soft parts are healed and hardened and the point of the nail is lifted out of the socket it has formed in the flesh. If the phenol does not seem to give satisfactory results, which will seldom happen, or, perhance, fails altogether, then Harnsberger uses the following powder:

℞	Gm. or c.c.		
Thymolis		66	gr. x
Mentholis		66	gr. x
Acidi boracici	4		ʒj
Aluminis q. s.	ad 15		℥ss

The alum should be pulverized finely and dried thoroughly; triturate all and apply freely. In mild cases the powder can be left on until the parts heal. In bad cases the applications may be renewed as thought best. A thin rubber cot should be worn on the affected toe to keep the remedy in place and to protect the parts from possible outside infection. Unless the secretions stain the powder, the applications need not be renewed every day. If it is necessary for the patient to go about, the affected part can be protected by properly applied pieces of thick felt kept in place by adhesive strips. Usually a piece applied to the inner side and top of the toe just back of the painful joint, gives ample protection; and, not only wards off painful pressure of the shoe, but hastens the healing process. Harnsberger has never seen a case so bad that it could not be cured by mild local means.

47 Pregnancy Following the Complete Removal of One Ovary, and at the Same Time the Major Portion of the Opposite One. J. E. Stokes, Salisbury, N. C.

44. **Jaundice in Pernicious Anemia.**—Vanderhoof reports a case of jaundice associated with weakness. There were no abdominal symptoms or evidence of obstructive lesion of the bile ducts. The blood-picture was typical of Addison's anemia. There was marked improvement of health and disappearance of jaundice under appropriate treatment with arsenic and the institution of proper hygienic measures.

45. **Pellagra.**—A very complete table of these sixty-six cases is offered by Tucker in his paper and also a very good question form which he got up for the Virginia State Board of Health for use in the study of pellagra. Forty-eight of the patients were females and eighteen were males. There were only ten negroes to fifty-six whites. In Tucker's opinion, negroes are less susceptible. Three of the ten negroes were reported to be mulattoes. The hygienic surroundings were poor in only sixteen cases. Ten patients rarely ate corn products and six never ate corn products or had not done so for years. This would seem to eliminate maize as the causative factor in pellagra. In only sixteen cases was the skin lesion the first manifestation. Seventeen patients died during the first attack; seven died the second year, one of these committed suicide. Five patients died after the second year; one died six years after diarrhea and two years after skin lesions. In three the course of the disease was unknown. Total deaths were thirty, a mortality of nearly 50 per cent. All deaths other than the suicide were attributable to the constitutional effects of the disease. Thirty-two of the living patients had one or more remissions. In three, the remission was thought to have lasted over one year. One case is in the first attack. Hexamethylenamin was the exclusive treatment given in fourteen cases in doses of from 20 to 45 grains a day. In seven, immediate improvement was noted, and the patients went into complete remission within four weeks and there was no return. In two, the same result took place, but no report has been received of their condition this year. In two, the hexamethylenamin was advised but the result has not been heard. One patient was given the drug for three days and committed suicide. One case of five years' standing cleared up with hexamethylenamin, except some nervous symptoms and the patient died several months afterward in convulsions but without gastro-intestinal or cutaneous symptoms. In one case hexamethylenamin was given to a patient in a moribund state. He died in a few days.

46. **Early Pulmonary Tuberculosis.**—For diagnostic purposes Ennett emphasizes the importance of the following: The tuberculous patient will usually come to his physician complaining of being "run down," and a careful history will usually reveal many of the following symptoms: He has little or no energy, becomes tired easily, spends restless nights, and may or may not have sweats, has some dyspeptic symptoms or complains of frequent "colds." These colds are usually described as "chest colds" instead of "head colds." He will probably have a slight but constant rise of temperature, usually in the afternoon, rapid pulse, even while at rest, chilly feelings, and possibly some loss of weight. Hypersensitiveness of the entire nervous system; hemoptysis; an occasional, non-productive, hacking cough, accompanied by a tickling sensation in the larynx, usually worse at night on retiring or in the morning on arising; hypersecretion of mucus in the respiratory tract; pain located anywhere in the chest,

but usually over the apices, and pleurisy are all significant and should be considered carefully.

54. **High Arterial Tension.**—High arterial tension is not in itself regarded by Goepp as an indication for direct corrective treatment by drugs, but as a diagnostic sign of value in a number of morbid conditions characterized by the absorption of toxic substances, poisons or disease products, and in the early stages of chronic interstitial nephritis and general arteriosclerosis. Lowering an excessive blood-pressure below a certain point, which varies for each individual, may be harmful instead of beneficial. While excessive arterial tension (above 180 millimeters of mercury, systolic pressure) is unquestionably an unfavorable prognostic sign, it may be present for years, and is not incompatible with a fair degree of health.

73. **Prevention of Dysentery in Infants.**—This investigation is very limited and the number of patients treated is few (ninety-five). The vaccine in no instance did harm, and the reactions in the majority were very mild and of short duration. Cases in which bacteriologically *B. dysenteriæ* were proved to be present, but in a clinically unrecognizable form, were not affected differently from those which were culturally negative. This may be due in part to the fact that this mode of vaccination produces an immediate passive immunity, while the bacterial vaccine is producing an active immunity. The work is of interest and holds out a possible means of preventing the great mortality from infantile dysentery during the summer months.

74. **Growth of Sarcoma and Carcinoma in Vitro.**—Lambert and Hanes report that in their experimental work, the transplantable sarcomata of rats and mice were found to grow very readily by the method of cultivating tissues *in vitro*. Sarcomatous tissue grows in conformity to a type which may be regarded as characteristic for tissues of mesenchymal origin. The growth of sarcoma cells *in vitro* consists in ameboid wandering into the surrounding plasma, karyokinetic proliferation, and evidences of active metabolism on the part of the cells. Mouse carcinomata can be cultivated *in vitro*. The outgrowth of carcinoma cells assumes a sheet-like form, only one cell in thickness. They migrate into the plasma by ameboid movement, the advancing edge showing numerous prolongations of the cytoplasm into pseudopods. Karyokinetic figures are frequently seen in growing carcinoma cells. The cells show evidence of active metabolism. Both sarcoma and carcinoma cells cultivated *in vitro* show active phagocytosis; carmin particles placed in the plasma are taken up rapidly by the growing cells.

75. **Cancer Immunity.**—It is said by Lambert and Hanes that sarcoma cultivated in plasma from immune animals grows quite as vigorously as in plasma from normal and tumor-bearing animals, thus affording further proof of the absence of specific cytolytic substances in the body fluids of animals immune to transplantable cancer. Animals may be successfully inoculated with sarcoma cultivated *in vitro*, although, in the case of rat sarcoma, there is evidence of diminished virulence. Subcultures of sarcoma cultivated *in vitro* may be made by transferring to fresh plasma the original piece of tissue, or a portion of the outgrowth. The duration of life of sarcoma cells under these conditions seems dependent only on a renewal of the medium.

76. **Immunity in Cancers of the White Rat.**—Indirect evidence is brought forward by Levin and Sittenfield through their investigation to show that immunity to cancer growth, but not to tumor grafting, is caused not by differences in intracellular nutrition, but by an active inhibitory influence of the organism of the host on the cancer cells. It appears from their experiments that a mouse tumor through a sojourn in the rat reacquires the characteristics of a spontaneous tumor; namely, it takes in a small percentage of inoculated animals, and this percentage increases in subsequent generations. But the diminution of the virulence of the tumor which takes place in the organism of the rat is due to congenital racial immunity of the latter. Furthermore, the immunity of the rat against mouse tumor is not due to conditions of nutrition, but is accompanied by an active noxious influence of the organism of the rat on the mouse tumor.

81. **Healing of Skin Wounds in the Frog.**—Ruth's experiments demonstrate the important point that the healing of epidermal wounds of the frog takes place in a practically identical manner in culture *in vitro* and in the body of the animal. They show further that the rate of growth of new epithelium which constitutes the process of cicatrization is accelerated by a diluted medium, both *in vitro* and *in vivo*. Thus, by increasing or diminishing the degree of dilution of the medium, or by injecting distilled water or hypertonic solutions into the animal, the rate of growth can, and will up to a certain point, be accelerated or retarded.

82. **Physicochemical Regulation of the Growth of Tissues.**—It is concluded by Carrel and Burrows that the degree of dilution of the culture medium has a marked influence on the rate of growth of splenic tissue. The maximum acceleration was obtained in a medium composed of three volumes of normal plasma and two volumes of distilled water. The growth in this hypotonic plasma was very much larger than in normal plasma. On the contrary, the growth of the spleen in hypertonic plasma was always less than in normal plasma. In other experiments, they found that in diluted plasma there was also an acceleration of the growth of the skin, the heart, and the liver of chickens. The skin of adult frogs also grew more actively in this plasma. The optimum degree of dilution varied according to the nature of the tissues and to the species of the animals. While the plasma containing two-fifths distilled water produced the largest growth of splenic tissue, a slightly less diluted medium was more favorable for the liver and the heart, and generally for the skin also.

83. **Cultivation in Vitro of Malignant Tumors.**—Experimental malignant tumors were found to grow *in vitro* extensively, and the cultivation of human tumors is also possible, although much more difficult on account of the liquefaction of the plasma.

97 Hospital Corps Instruction on Board Ship. W. S. Pugh, U. S. Navy.

94. **Disappearance of Beriberi from Philippine Scouts.**—Chamberlain shows that beriberi has disappeared from the Philippine (native) scout organizations during the last half of the year 1910. There have been no sanitary improvements to account for this, except the changes in diet, and there has been no corresponding decrease in the admission rate for diseases other than beriberi. There was no corresponding decrease in the incidence of beriberi in the general Filipino population or in the Philippine (native) constabulary. The decrease in admissions for beriberi among the scouts was clearly marked for four months before the use of undermilled rice began. The decrease in admissions was well under way before the mongos, camotes and ginger root of the new ration began to be issued. The decrease in the admissions for beriberi was due either to unknown causes acting coincidently with a reduction in the amount of rice used and the addition of a legumen, or was due directly to these dietetic changes. As no other reduction in admissions even approaching that of 1910 has occurred since the organization of the scouts in 1901, the authors do not believe that the present decrease is due to coincidence. The facts do not oppose the polished rice theory of beriberi production. On the contrary Chamberlain believes that they support it.

96. **Protection from Typhoid by Inoculation.**—Lyster details the experience of inoculating an entire regiment in order to prevent the spread of typhoid. After the completion of the inoculation of the regiment (376) and nearly seventy civilians at the post, including the teamsters, no new cases appeared. Later this regiment, except one troop, left post on a twenty-one day march, some 300 miles. On the return of the command, after spending twenty-one days in a country where typhoid is known practically throughout the year, and having lived under war conditions, the sick report is stated by the commanding officer to be *nil*. No subsequent cases of typhoid developed.

100. **Malignancy in Tumors.**—Special emphasis is placed by Gurd on the relative malignancy in tumors, and the changes which take place in certain new growths of apparently benign type, but in which malignant characteristics develop. Such conditions, he says, are usually loosely and falsely grouped under the heading of malignant degenerations.

102. **Ingrown or Overgrown Toe-Nail.**—Gessner proposes a modification of the Van Meter incision, consisting in the substitution of a hexagon for the diamond excision. The edge of the nail is paralleled by a cut running its full length, about ¼ of an inch from it. From ¼ to ½ of an inch further from the nail another cut is made, parallel with the first and equally long. A V-shaped incision joins the first two cuts at each end and completes the hexagon. The removal of the skin and fascia between these lines of incision leaves a gap, suture of whose edges pulls the skin away from the nail edge evenly throughout its entire extent.

109 In the Twilight. C. E. Warren, North Easton, Mass.

107. **Mattoids.**—This is the term which MacDonald proposes for the word "cranks." He says that the word crank has been so misused, if not abused, that the term "mattoid" is preferable. The mattoid, then, is an abnormal person, characterized by want of balance, eccentricity or egotism. He is usually sincere and insists on his ideas, which are generally extreme and frequently absurd. He is generally sane, but may be semi-insane, and sometimes insane. He is usually above the average, sometimes showing talent, but rarely genius. He often has a distorted view of life, leading him into all kinds of uncertainties, inconsistencies and vagaries and he is frequently called odd, queer, strange, freakish and the like. Mattoids show defects and disproportion in character indicating as much talent in one direction as they do little in another. There is often a nervous element which gives force and energy. They may be gifted in speech, art and poetry, but deficient in judgment, showing no continuity and unity of direction in their lives. They often have altruistic but wild theories, utopian ideas or absurd projects, which they express in public speeches or books. But they are generally incapable of accomplishing anything. The mattoid may pass from one mental condition to another, and in the course of his life manifest all of the characteristics mentioned above. He is often on the borderline between sanity and insanity. He is more liable to get into trouble, commit crime or become insane than people in general.

117. **Renal Tuberculosis.**—In the light of recent experience with spinal anesthesia in cases of damaged kidneys, Cabot is inclined to regard this as the anesthesia of election, at least for the exploratory part of the operation. Anesthesia extending well up to the costal margin is readily obtained and is entirely satisfactory for the exposure and opening of the ureters. The urine can then be collected and conclusions drawn without subjecting the patient to the strain of general anesthesia. Should nephrectomy be decided on, it may either be done at once under a general anesthetic, or postponed to a future occasion. Cabot has not found spinal anesthesia satisfactory for nephrectomy and does not advise its use, but for the preliminary determination of the kidney function, he believes it will lower the mortality in properly selected cases.

6. **The Alimentary Canal in Health and Disease.**—The results of his experiments, made to determine the sensibility of the esophagus, stomach and intestines to tactile, thermal and chemical stimulation, are detailed by Hertz. He says that the alimentary canal from the commencement of the esophagus to the junction of the rectum with the anal canal is completely insensitive to tactile stimulation. The introduction of ice-cold water or hot water at any temperature between 40 and 50 C. into a normal stomach produced no sensation of any sort. His observations show that 0.4 and 0.5 per cent. hydrochloric acid, introduced into the esophagus or the empty stomach of normal individuals through a tube, produces no sensation of any kind. The introduction of 0.5 per cent. hydrochloric acid through the gastrostomy wound into the stomach of patients with esophageal stenosis also produces no sensation. It is thus clear that the pain, which is often associated with excess of free hydrochloric acid in the stomach, cannot be due, as has generally been believed, to the excess of hydrochloric acid alone, as it is certain that as much as 0.5 per cent. free hydrochloric acid is never present in the stomach. Moreover, many cases in which excess of free and of active hydrochloric acid is discovered by chemical analysis are not associated with pain or other gastric symptoms, and the excess present in painful conditions may persist after the pain has been completely relieved by treatment. It may be concluded, therefore, that the presence of an excessive quantity of hydrochloric acid in the stomach is only one manifestation of a disease, in which pain is another, and tha it is not the cause of the pain. In six cases of gastric ulcer, in all of which the diagnosis was confirmed by operation, 4 ounces of 0.5 per cent. hydrochloric acid introduced into the empty stomach by a tube produced no sensation whatever. The same result was obtained in another case in which a mixture of hydrochloric acid with pepsin was used. These observations show that, contrary to the common belief, contact with free hydrochloric acid is not the direct cause of the pain in gastric and duodenal ulcer. That the acid is, however, in some way connected with the production of the pain there can be no doubt, as rapid relief always follows the administration of an alkali.

Crême de menthe, introduced by a tube into the empty stomach, gives rise to a sensation of warmth which may occur immediately, but more frequently only develops in the course of a minute or two. A similar result was obtained with the 48 per cent. alcohol, but not with peppermint water, so that it is the alcohol and not the peppermint which produces the sensation after the liquor is introduced into the stomach. Crême de menthe also produces an immediate burning sensation in the epigastrium when poured through a tube into the lower end of the esophagus. This is a much stronger sensation than that produced in the stomach, but it is impossible to distinguish the locality of the two. The burning sensation in the esophagus is produced by the alcohol, as the 48 per cent. solution has the same effect, while the peppermint water, if warmed to the body temperature, produces no sensation. It may be concluded, therefore, that the immediate burning sensation produced by the liquor is in the esophagus, and that the subsequent feeling of warmth is in the stomach. Both are due to the alcohol alone. It was found that the lower *end of the esophagus is so sensitive to alcohol* that special precautions had to be taken in testing the sensibility of the stomach in order to prevent a few drops reaching it when the tube was withdrawn. Alcohol in a strength greater than 25 per cent. gives rise to a sensation of burning when applied to *the mucous membrane of the anal canal*, but when introduced into the pelvic colon through a sigmoidoscope or into the more proximal parts through a colostomy opening, a strength of 50 or even 90 per cent. is required. After a sensation of heat has been produced, the repetition of the experiment a few minutes later may have no effect, owing to the protection of the mucous membrane by mucus, which is secreted as a result of the irritation caused by the alcohol. Glycerin produces no sensation when applied to the rectal mucous membrane; the characteristic sensation occurs only when it is applied to the anal canal. The sensation produced by a glycerin enema or suppository must, therefore, be due to a small quantity escaping from the rectum into the anal canal, and the defecation reflex to which it gives rise probably originates in the anal canal, and not, as formerly believed, in the rectum.

8. **Railway Accidents.**—Two cases of cerebral fat embolism are reported by Godlee and Williams. Both patients presented similar symptoms and signs. They both had fractures of the thigh, in one case a comparatively simple fracture, and in the other two simple fractures, together with some crushing of the bones about the knee-joint and a lacerated and contused wound of the foot. The patients were both given chloroform for the setting of the fractures. Within about twelve hours both went into a comatose state more or less suddenly, without any previous noticeable pulmonary distress, the temperature rose rapidly, the pulse was of low tension and rapid, and there were no localizing signs in the nervous system pointing to a lesion in any particular part of the brain. Both might have been thought to be cases of cerebral compression if it had not been for the character of the pulse. One patient was trephined over the right side because he had evidence of injury to the skull on that side. The authors do not believe that the operation hastened death, the only cause of which that could be demonstrated was fat embolism of the brain. The other patient recovered to a slight extent from what seemed to be an almost hopeless condition, and his death was no doubt partly due to a secondary bronchopneumonia; in this case also some of the typical signs of cerebral compression were absent.

Attention is called to three points of especial interest. 1. The difference in the extent of the original injury in the two cases. Whereas one might have expected fat embolism to occur in the case where there were several fractures, some of which were of a crushing nature, there was nothing about the simple fracture in the other case to suggest the likelihood of its occurrence, or at all events of its causing any grave symptoms. 2. The absence of dyspnea or other symptoms of pulmonary embolism in one case, and the fact that the other patient only complained that his bandages felt tight. 3. The resemblance superficially of the condition to that of cerebral compression; the characteristic pulse of compression was never observed. There were never any signs in the nervous system pointing to a localized injury to the brain.

10. **Direct Bronchoscopy.**—Two cases are cited by Tilley, indicating the value of this method for the detection and removal of foreign bodies impacted in the lower air passages.

11. **Ionization in Inflammatory Diseases of Lower Bowel.**—Webb details his results obtained in the treatment of colitis by the ionization of zinc salts in the bowel. Of fourteen patients so treated, only one was not cured or benefited.

12. **Ascites Treated by Lymphangioplasty.**—In the case reported by Stoney and Moorhead, the introduction of artificial silk lymphatics, according to the method suggested by Sampson Handley in 1910, was followed by disappearance of the ascitic fluid. The existence of chronic fibrous peritonitis with hepatic cirrhosis was demonstrated at the operation. The authors do not claim that the improvement which occurred is necessarily the result of the lymphangioplasty, as ascites of the type here presented may disappear spontaneously (as occurred for a time in this case during the first stay in the hospital), or may disappear after a simple laparotomy. The fact, however, that some fluid reaccumulated after the operation suggests that the mere laparotomy was not of itself the cause of the later improvement, but rather that the reaccumulation took place prior to the establishment of an efficient circulation via the silk lymphatics, and that once a sufficient circulation was attained no further transudation accumulated.

14. **Acute Hemorrhagic Pancreatitis.**—The case reported by Gillespie shows the features which have been well termed "an abdominal catastrophe." There was a confused picture of shock and of hemorrhage, so much so that but for the localization of the pain to the upper abdomen and the history of regular menstruation, the diagnosis would have been that of a ruptured extra-uterine pregnancy. Rigidity of the recti was present, but it was neither so marked as in cases of perforation, nor so well defined as has been insisted on by other observers. There was nothing which could be called distention, but it is of interest to note that diminution of liver dulness was present. The onset was definitely gradual; the pain increased in intensity until it was so severe as to attract attention. No light is thrown on the obscure question of causation. The abdomen was opened above the umbilicus by a vertical incision, and separation of the fibers of the left rectus. The lesser sac was at once seen to be filled with dark blood. No fat necrosis was observed. The gastrohepatic omentum was freely opened and the blood was evacuated. The peritoneum over the pancreas was freely torn and more blood removed. The lobules of the pancreas showed up a light yellow against the effused blood. The gall-bladder and the bile passages were palpated but nothing abnormal was found. The patient's condition was so serious that no further examination was attempted. Gauze was passed down to the pancreas and packed along it from tip to head. A rubber tube was also passed down beside the emerging piece of gauze. The abdomen was closed in a single layer.

20 Hydatid Cysts of the Liver in a Boy; Operation. A. J. Cleveland and J. Burfield.

18. **Oculomotor Type of Polioencephalitis.**—For some years Stephenson has observed a group of cases in children, the chief characteristic of which is the sudden onset of strabismus at an age when ordinary squint is not altogether common. The cases are encountered in children often of tender age. The condition may arise without obvious cause. On the other hand, it may be observed after some childish ailment, as scarlet fever or measles, or an injury, a fright, or some trifling operation, as vaccination or circumcision. The child, often apparently in usual health, is put to bed, and on awakening next morning is found to present squint. Stephenson's observations lead him to conclude that the oculomotor symptoms in these cases depend on an acute focal encephalitis, quite analogous with the better-known forms of that disease. He has seen twenty-eight such cases, all the patients being under 6 years of age, and half of the number under 1 year. The condition was associated comparatively seldom with other symptoms indicative of a cerebral disorder. Zymotic diseases (measles, 2; scarlet fever, 1; influenza, 1; small-pox, 1; pertussis, 1) appeared to be important factors in its causation. Although the paralysis may affect any of the extrinsic muscles of the eyeball, yet in three-fourths of the cases, the external rectus muscle alone is involved. The extrinsic musculature of the eye is seldom attacked. Stephenson says that the common form of encephalic strabismus is very apt to be confused with ordinary concomitant convergent strabismus.

the organism with acids. None of the mineral acids induced with thirty-six illustrations.

29. **Acid Intoxication and Diabetes.**—Considerable experimental investigation by Labbé and Violle has led to results confirming the assumption of the acidosis as the main factor in diabetic coma, but the special toxicity of the acids in question evidently adds to the injurious effects of the flooding of the organism with acids. None of the mineral acids induced any tendency to coma in the animals, but the organic acids, such as butyric, lactic, propionic and beta-butyric acids all had marked though variable power to induce coma. The acids free from a secondary alcoholic action, such as butyric and propionic acids, displayed the most powerful coma-producing action. The research confirms the importance of alkaline treatment of diabetic coma and in prophylaxis.

37 Cysts in the Uterus. O. Frankl.
38 Adenomyoma of the Ligament of the Ovary. O. Frankl.

33. **Inflammatory Disease in the Pelvis.**—Thaler reviews the experiences at Schauta's clinic in Vienna with 6,000 cases of inflammatory processes around the uterus. Operative treatment is indicated, he says, only after failure of a course of conservative treatment, except where pus has to be let out. When operative measures become necessary, extirpation of the organ involved is necessary; palliative measures are useless. The appendix should be removed on suspicion of trouble or adhesion to the inflammatory process elsewhere. The radical operations alone result in permanent cures; whenever conditions require draining, any conservative operation, leaving the uterus, is distinctly contra-indicated, as also when there is a tendency to excessive genital hemorrhage. Over 93.5 per cent. of the 828 patients given radical operative treatment were permanently cured, and the symptoms of the premature menopause were annoying in only a few cases. The only exception to the rule for radical operative treatment is in case of tuberculosis of the genital organs. Only five of the sixteen patients with tuberculosis of an ovary or tube were permanently benefited by the radical operation and the postoperative mortality was 25 per cent. In the experience of the last sixteen years not a single case has been encountered of a primary ascending tuberculous process in the internal genitals. In 40 of the total 6,179 cases the inflammatory process in the adnexa was evidently secondary to an extra-uterine pregnancy.

34. **Sarcoma in Female Urethra.**—Nebesky adds another to the fourteen cases on record, and states that four of the total fifteen were free from recurrence at last accounts. The interval since the operation is nine years in his case; the patient is a farmer's wife, now 48 years old. In two cases an existing pregnancy was apparently not disturbed by the operation. Flatau provided for comparative continence of urine by suturing the neck of the bladder in the vagina which is kept packed with gauze. Nebesky sutured the stump of the urethra to the vulva.

35. **Menstrual Pains Between the Periods.**—Theilhaber ascribes the pains to spasmodic contraction of the musculature of the uterus, similar to spasm of the cardia and pylorus. Treatment on this basis has always proved effectual in his experience, that is, by enlarging the internal os. It is not enough merely to dilate it; a permanent cure is ensured only by slitting the os, or, better yet, resecting a small strip. He has done this in 100 cases of dysmenorrhea in the last twelve years and 66 per cent. of the patients were entirely cured and 17 per cent. were much improved. In the others who were not benefited, the trouble must have been more of a hysteric nature. Success was constant in the five intermenstrual colic cases in which he has applied this same measure.

36. **Protection of Peritoneum Against Infection.**—Hoehne reports experiments on four guinea-pigs and eighty-five rabbits which confirm the fact of a reactive inflammation in the peritoneum after injection of oil or other irritating substance. When this peritonitis is of only a few hours' standing, it favors absorption of germs by the peritoneum, but if it is of twenty-four hours' or a few days' standing it checks absorption from the abdominal cavity very materially or prevents it altogether for many days and weeks. Germs thus vegetating in the abdominal cavity and not able to pass thence into the general circulation, rapidly die off, even the most virulent, in the course of four days. The peritonitis once installed summons to the region such powerful bactericidal forces that the invading infectious germs are soon conquered. Small intraperitoneal injections of olive oil, sesame oil or camphorated oil, up to 10 c.c. proved entirely harmless for the rabbits, while larger amounts, 20, 50 or 100 c.c. sometimes induced fat embolism in the lungs or severe local or general injury.

39 *Injection and Infiltration Treatment of Sciatica. F. Barth.

39. **Sciatica.**—Barth reviews the modern methods of treating sciatica and their results, preferring, himself, a combination of the Hay and Alexander technics, that is, injection of 10 c.c. of physiologic salt solution in the nerve at a point between the tuberosity of the ischium and the greater trochanter, or at some point where the sciatic is most sensitive, supplementing this with bloodless stretching of the nerve. The main point is a correct diagnosis. Only with sciatica does pain occur as the patient strains the abdominal muscles; if there is pain in the calf or buttocks as the patient coughs or sneezes, sciatica may be regarded as certain. Another sign is a tendency to lordosis in the lumbar vertebræ as the trunk is bent forward, but no tendency to lordosis otherwise. The patient instinctively resists the tendency to straighten the spine as liable to induce pain. A still more important sign of sciatica is the loss of the Achilles reflex. The knee-jerk is not affected by sciatica.

40. **Leukocytosis in Diagnosis and Prognosis.**—Sonnenburg declares that physicians should adopt the leukocyte count as a routine measure. He applies to it what was said forty years ago in regard to the importance of taking the tempera-

ture, insisting that it is equally indispensable "because every phenomenon taking place in the diseased body should be studied; because it can be studied with a precision obtainable with few of the other phenomena; because it can be neither simulated nor concealed; because any deviation from normal findings indicates disturbance; because it reveals the success of therapeutic measures and warns of injurious influences, and is an index of the transition from one stage of the disease into another, and, finally, because it often announces the impossibility of recovery." These statements, made originally in regard to the clinical thermometer, are equally *true*, he says, of the leukocyte count and the neurophil blood-picture. It is a great advantage to know the leukocyte count; how the physician interprets the blood findings for diagnosis and prognosis in the individual case is his affair, but he should not neglect this valuable aid.

To show its importance, Sonnenburg reports ten typical cases of appendicitis, as the peritoneum reacts more readily and more intensely, perhaps, to inflammation than other organs. A leukocyte count of 20,000 and "Arneth" 20 per cent. In one case paralleled the acute appendicitis with gangrene, mild infection, good resisting powers and favorable prognosis, while in another case the leukocyte count of 15,000, Arneth 47 per cent., indicated severe infection, and the child died as the Arneth rose to 66 per cent. In another case the clinical picture was mild but the leukocyte count was 30,000, Arneth 6 per cent. Operation was done in this case on the leukocyte count alone, and the findings confirmed the grave danger of delay. In another case the clinical manifestations were serious but the leukocyte count was only 9,000 and the Arneth 12 per cent. The appendix had perforated, but the pus was completely encapsulated. [The Arneth formula has been described in THE JOURNAL, Dec. 25, 1909, page 2180, and an improved technic was given Jan. 8, 1910, page 124].

Grawitz' experimental research has confirmed the fact that muscular strain will raise the leukocyte count. This explains the leukocytosis of from 20,000 to 30,000 found sometimes with normal deliveries—the result merely of the violent muscular contractions of the uterus. The muscular effort in whooping-cough may also explain the leukocytosis in this disease. The rigid contraction of the abdominal musculature also plays a part in raising the leukocyte count with incipient peritonitis. These physiologic influences on the leukocyte count from digestion and muscular effort should be duly estimated in interpreting the leukocytosis of inflammation and febrile diseases, especially in differentiating typhoid, suppuration and pneumonia. The intensity of the leukocytosis corresponds in general to the severity of the infection; the most correct index of this, however, is the hemolytic action on the red corpuscles. He insists that the leukocyte reaction cannot be accepted under all circumstances as an index of the general vital energy of the organism.

Franz discusses the leukocyte count from the standpoint of the gynecologist and obstetrician, not ascribing much importance to it.

45. **Unfavorable Experiences with Salvarsan in Syphilis of the Eye.**—Falta warns that if the optic nerve is already diseased, salvarsan is liable to do harm. With syphilitic disturbance of the retina, chorioid and vitreous body, it is much safer to apply the ordinary mercury and iodid treatment, giving salvarsan only in case this fails. In his two cases as also in one of Finger's, the aggravation of the disturbances in the depths of the eye under salvarsan did not retrogress when mercury was given; under other conditions mercury generally promptly controls disturbances of this kind. The salvarsan seemed to have rendered them refractory to the ordinary measures. He warns that salvarsan should never be given without careful examination of the eye. He conferred with Ehrlich in regard to his first case, and Ehrlich advised a cautious repetition of the salvarsan injection, but as Falta had met with his second similar and severer case in the meantime, he did not dare to risk giving the salvarsan again. In the first case bilateral neuroretinitis had existed for a time and became aggravated under salvarsan but improved somewhat under mercury. In the other case an acute neurochorioretinitis increased under salvarsan, and it shows only slight improvement under mercury for nearly a *month* to date.

47. **Prophylaxis and Treatment of Septic Abortion.**—Winter states that the septic cases form fully 27 per cent. of all abortion cases at his clinic (Königsberg) and he here analyzes 100 cases. The mortality was 13 per cent.; only 54 per cent. had a normal course. Study of this material teaches four lessons: 1. The first task is diagnosis. A temperature in the axilla over 38 C. (100.4 F.) is pathologic but it must not be forgotten that spontaneous abortion may occur in the course of an infectious disease, or that an infectious disease may casually occur along with an abortion. 2. The second task is to determine the extent of the infection. If the infection has passed beyond the uterus, decomposition of the uterine content is of secondary importance. Any attempt to evacuate the uterus is liable to do more harm than good; many a septic abortion has terminated fatally on account of this alone. In general practice many errors have been committed in this line, either from disregard of the extra-uterine infectious conditions or from the mistaken view that removal of the primary focus will have a favorable influence on the secondary foci. Before attempting active treatment of the abortion, the fact that the infection is limited to the uterus must be demonstrated. 3. The septic abortion diagnosed and the vicinity of the uterus still free from infection, the further conduct of the case must depend on the bacteriologic findings except when hemorrhage forces immediate intervention. Bacteriologic examination of the secretions, taken from the depths of the vagina, may show the presence of hemolytic streptococci, and it is wise to wait even twenty-four hours for the results of this examination, as hemolytic streptococci reveal that the trouble is an acute infectious endometritis in connection with an abortion. Here the danger with active treatment is very great. No local measure should be attempted, but everything done to increase the resistance; ergot is useful by limiting absorption from the contracted uterus wall and promoting expulsion of the relics of the ovum. This expectant treatment is tedious but the advantages are very great. In five such cases in his experience, the hemolytic streptococci spontaneously disappeared by the end of 4, 7, 11 or 23 days; then the uterus was safely evacuated without harm. If bacteriologic examination shows only ordinary streptococci, staphylococci, colon bacilli or saphrophytes, the uterus can be evacuated at once. Serious consequences need not be anticipated. 4. In active treatment it is important to disinfect the vagina and uterus as thoroughly as possible, rinsing out the germs thoroughly by prolonged irrigation of the uterus, carefully refraining from anything that might injure the vitality of the tissues or open fresh wounds. Injury of the decidua is less harmful than injury of the musculature, but any erosion opens the portals for invasion by the germs. The use of the curette should not be permitted with septic abortion. Among other points which Winter emphasizes is that flowing blood is much less likely to become infected than stagnating blood and secretions. This should be borne in mind when considering tamponing of the vagina.

49. **Revulsion.**—Bloch explains by the light of allergy the success obtained by physicians of the olden times with revulsion measures. Their facts were sound, like those reported seven years ago by Brocq, showing the benefit of revulsion in certain conditions of chronic intoxication. Bloch reports a case in which a scalp disease developed into a deep parasitic sycosis. After weeks of ineffectual treatment of all kinds, the patient was inoculated on both forearms with a culture of *Achorion quinckeanum*, a fungus closely allied to the trichophyton fungus in question but notable for its power to induce intense allergy. The success surpassed anticipation, the inoc-

ulation evidently transforming conditions so that all the morbid processes retrogressed. The new infection allergized the organism, and enabled it to throw off both the old and the new infection.

50. **Injury of the Kidneys from Salvarsan.**—In this communication from the medical clinic at Leipsic in charge of von Strümpell, Mohr reports three cases of serious injury of the kidneys under salvarsan. In one case severe collapse and diarrhea followed intravenous infusion of the salvarsan, with other symptoms of arsenic intoxication and acute injury of the kidney. It was evidently an acute degeneration of the parenchyma, such as is found in injury of the kidney from corrosive sublimate. The changes had nothing in common with nephritis but were probably the same as those noticed in the sections of the kidney of a young man who died two months after salvarsan treatment (No. 5 of Ehrlich's compilation). The disturbances in Mohr's case rapidly subsided, confirming the reactive nature of the disturbances and the rapid elimination of the arsenic when the salvarsan is given by intravenous injection. The disturbances in the two other cases followed intramuscular injection of the salvarsan and they were evidently a true nephritis following on the toxic degeneration of the parenchyma. In the first case the severe hemorrhagic nephritis has grown constantly worse and a fatal termination is impending. This patient is a young woman and the urine was normal and there was no history of kidney trouble, but two months after the intramuscular injection of 0.5 gm. salvarsan the severe nephritis was in full development. In the third case polyneuritis developed with symptoms of nephritis in less than three weeks after the injection of 0.7 gm. of salvarsan. These cases seem to confirm the assumption that the salvarsan undergoes toxic transformation in the muscular deposits. They teach the necessity for watching over the kidneys after salvarsan treatment as trouble may manifest itself after a long period of latency. Mohr refers also to instances of injury of the kidney under salvarsan reported by Géronne, Jadassohn, Scholz and others, besides the case mentioned by Ehrlich.

60 Camphorated Oil in Treatment of Unencapsulated Suppurative Peritonitis. A. Krecke.
61 The Vaginal Method in Gynecology. D. v. Ott.

54. **Roentgen-Ray Treatment in Gynecology.**—Döderlein says that he regards the use of the Roentgen rays in therapeutics as still an experiment, but that this method of treatment is giving fine results in certain cases, especially in climacteric hemorrhage for which neither palpation nor microscopic examination can discover whether the hemorrhage is the result of degeneration of the vessels in the uterus or of disease of the ovaries, myometrium or endometrium. All other methods of treatment generally fail unless the apparently sound internal genitals are removed when the hemorrhages are weakening the patient to such an extent that it is impossible to wait for the natural retrogression of the genitals with the approaching menopause. It is in this group of cases that the Roentgen rays show themselves supreme; in the simplest and most harmless manner the internal genitals are hastened into the menopause stage by exposures of the ovaries to the rays. They act in such an elective manner that the internal secretion of the ovaries does not seem to be affected. Döderlein has thus treated twelve women with an interval since of over six months. They were women between 40 and 50 with violent hemorrhages, the hemoglobin being reduced to only 30 per cent. in some, and the red count very low. A very few exposures sufficed to put an end to the ovarian functioning at fault and the general health promptly recuperated. The closer to the natural menopause, the more rapidly effectual the Roentgen rays. Reifferscheid has also reported similar gratifying results in this class of cases. In younger women this treatment has proved effectual in curing dysmenorrhea, but there is danger in the young of malformation of the embryo in conception later. Intense vulvar pruritus, rebellious to all other measures, subsided completely in Döderlein's two cases of this kind in women 29 and 56 years old. The danger of cancerous degeneration of myomas and of exacerbation of the hemorrhages from a myoma, close the door practically to Roentgen-ray treatment of myoma. Albers-Schönberg's fatalities with it teach that at least patients with 40 per cent. hemoglobin and great losses of blood from myomas must be excluded from this treatment.

57. **Massage and Gymnastic Exercises During Pregnancy and the Puerperium.**—Kirchberg does not hesitate to state that constipation yields invariably to a correct course of massage and exercises, including constipation in pregnancy and the puerperium. He describes a number of exercises and massage manipulations, the patient aiding by deep breathing in jerks, three pauses in each inspiration and expiration, drawing in the breath rapidly, holding it and then slowly expelling it. The staccato deep breathing and pauses exercise both diaphragm and abdominal muscles and promote the circulation, thus warding off varices. Among other useful exercises for the pregnant woman is to have her lie on her back, twist, bend and lift the legs. Twisting the legs from side to side with the knees bent, exercising against resistance, acts particularly on the abdominal muscles. He ascribes the development of the breasts to the condition of the pectoralis muscles, and deep breathing and other exercises to develop these muscles, he says, aid in developing the bust, which massage of the breasts alone is unable to accomplish. Frequent reclining with the pelvis raised will aid in curing a tendency to varices and hemorrhoids. Any rise in temperature, he says, directly contra-indicates massage under any conditions. With uncontrollable vomiting, massage and exercise are indispensable adjuvants.

59. **Treatment of Recurring Cystocele.**—Brenner raises the mouths of the ureters in the bladder, detaching them from their base in the wall, and then draws a catgut suture through the tissues beneath each, tying the ends to draw the tissues up into a stout fold below each ureter mouth. The catgut takes hold at the same time of the stout connective tissue between the ureters and part of the ligament, thus obtaining a firm hold. The operation is done by a laparotomy and proved successful in the case reported of inveterate recurring cystocele of obstetric origin.

70 *Salvarsan in Pneumonic Plague. O. Schreyer.
71 General Anesthesia by Intravenous Injection of Anesthetics. (Ueber intravenöse Narkose.) L. Burkhardt.

62. **Operative Compression of the Lung.**—Wilms found that the size of the half of the chest involved was materially reduced by resecting over an inch of the ribs close to their junction with the spine. This was easily done through three transverse incisions in the musculature of the back after a single lengthwise incision through the skin. The ribs not only slid backward after they were cut, but also slid downward, thus compressing the apex of the lung in particular. He has applied this measure in one case with excellent outcome. The patient was a young woman with tuberculosis of

the left upper lobe for fifteen years, recently showing signs of aggravation, with a tormenting cough, and 10 c.c. of sputum a day. Radioscopy showed a distinct cavity in this lobe, but the general condition was good. The patient ceased to cough by the end of the third week after the operation and there was no further expectoration. It had been intended to supplement this operation by dividing the ribs in front close to the sternum, but the desired result had been attained without this, so nothing further was attempted. Wilms reenforced the compression by strips of plaster, binding down a roll of gauze along the wound. The patient also lay on the affected side to enhance the compression of the chest. A compressive bandage might also be applied. He urges others to seek out the cases of chronic isolated indurated tuberculous processes liable to be benefited by immobilization of the lung and give this method a trial.

65. **Study of the Pulse.**—Christen declares that the old-fashioned method of palpation of the pulse is more reliable than the apparently more scientific method of sphymography. He has devised a method for registration of the features of the pulse which he claims presents with mathematical precision the volume of the blood and the force it displays in the pulse. The stasis curves thus obtained (*Stauungskurven*) take the place of palpation of the pulse, substituting an exact mathematical-physical method—energometry—which throws new light, he says, on the dynamic conditions in the circulation.

66. **Phonendoscope in Testing the Hearing.**—Streit stands the tuning fork on the base of the phonendoscope and then records the second when the patient, by raising his finger denotes that he has ceased to hear the tuning fork through the tube through which he is listening while the examiner is listening through the other tube. It is also possible to convey the sound through the Eustachian tube to the ear by this means, connecting the phonendoscope tube with a catheter.

69. **Injury of Kidneys from Salvarsan.**—The first of the three cases reported by Weiler is the same case of hemorrhagic nephritis described by Mohr and summarized above in abstract 50. Weiler's communication issues from the dermatologic clinic at Leipsic, in charge of Rille. The course of the nephritis in his three cases was more severe when the salvarsan had been given by intramuscular injection. He concludes with the remark that it is possible that the three individuals in question might have been especially predisposed to kidney trouble, but it is also possible that the kidneys in other patients may have suffered to a slight extent under the salvarsan treatment. Such injury may remain latent for a time and perhaps, if the salvarsan is given again or some other source of irritation develops, may manifest itself clinically later. He quotes Bornstein's finding of 0.0031 gm. arsenic trioxid in the kidneys and over twice this amount in the liver of a man dying two weeks after an intramuscular injection of salvarsan. Rille has also reported large amounts of arsenic demonstrable in the necrotic focus in the gluteal muscles at necropsy sixty-four days after an intramuscular injection of 0.7 gm. salvarsan. It is remarkable, he adds, that a few patients who developed albuminuria under mercury showed no signs of injury of the kidneys under salvarsan. Werther has reported a case in which a girl of 17 developed transient hemorrhagic nephritis after intravenous injection of 0.25 gm. salvarsan and it has recurred later in an acute transient form without further administration of salvarsan. Martius has reported an acute morbid process in a contracted kidney, the patient, a man of 39 with old changes in the kidney and arteriosclerosis, dying five hours after intravenous injection of 0.5 gm. salvarsan in 250 c.c. of fluid. In Treupel's experience, chronic nephritis on a syphilitic basis seemed to benefit by the salvarsan treatment, the albuminuria declining. He reports two cases in which traces of albuminuria developed after intravenous injection of the salvarsan, the only ones indicating possible injury of the kidney among his 250 cases. Sellei has reported two cases of latent nephritis aggravated by the salvarsan; in one of these there was albuminuria to six per thousand and hematuria the day after the intravenous injection of salvarsan, eight weeks after a subcutaneous injection of the same. The hematuria rapidly subsided but the albumin still amounted to two per thousand a week later.

70. **Salvarsan in Pneumonic Plague.**—Both of the two patients given salvarsan died, but one showed transient benefit.

76 Sound for Urethral Massage. (Eine "Rosenkranzonde" für Urethralmassage.) W. Tittinger.

75. **Automobiling Speed Mania and Impotency.**—Notthafft reports four cases of sexual impotency in wealthy married men fond of automobile speeding and one in a chauffeur. He knows of similar cases in the experience of others. The sexual depression developed in from three months to three years after special devotion to the sport. He ascribes the impotency to a cerebral neurasthenia from the nervous strain of the speeding; this assumption is sustained by recovery of normal tone when the automobilist refrains from speeding and drives his machine with ordinary prudence. Notthafft cites statistics which show that 12.1 per cent. of the 49,941 motor vehicles in the German empire were responsible for some accident serious enough to be reported to the authorities during 1909, a total of 6,063 accidents, involving 225 drivers, 487 other occupants of the car and 2,333 outsiders. He calculates that the driver of the car was to blame in 86 per cent. of all the accidents. The danger of speeding is not only for the public; the driver knows that he is taking his life in his hand and that he has one foot in the courts, for he is never certain that he may not run into some one at any moment. The intense concentration of mind required in speeding, the anxiety and the jar of the car—all tend to induce neurasthenia. The laws to regulate speeding are consequently not only in the interest of the public but of the automobilists themselves. Notthafft remarks that the attempts to limit the speed to a certain number of miles an hour does not answer the purpose. It would be better to make the general rule "No fast driving" apply to automobiles as well as to other vehicles, instead of setting a special speed limit. It is so often impossible to prove when this limit has been exceeded even when all know that the machine was being driven too fast.

Zeitschrift für klinische Medizin, Berlin

80. **Circulation and Diaphragm.**—Study of the pulse in patients whose diaphragm was unusually high or low showed that the circulation in the legs was better when the diaphragm was high, as the quadrate foramen was thus left open. When the diaphragm was low, this foramen is more squeezed together and the flow of blood up from the lower part of the body is thus impeded. At the same time, deep breathing pushes the diaphragm low down and it thus presses on the liver and liver veins and thus promotes the circulation in the region.

the most attractive. Some will want to see the Grand Canyon of the Arizona, a sight worth a trip across the country. Others will feel more favorable to the Pike's Peak country, Manitou, the Garden of the Gods and the various attractions of that part of the Rocky Mountains. Others will have a great desire to see the Yellowstone Park and its wonders. Still others will seek the northwestern part of the country—Oregon, Washington, etc., and the attractions of the Canadian Rockies on the Canadian Pacific. Not all of these can be seen on one trip, even on the round trip. Each individual should make up his mind what he is most anxious to see and then study the various itineraries and learn which one will best suit him.

The advantages of selecting one of the special trains, rather than to go by the regular trains, are the additional conveniences provided, the pleasure of traveling with friends and acquaintances, and the relief from the cares of looking after change of trains, hunting up conveyances for side trips, guides, etc., and the satisfaction of having everything provided in advance for comfort and for entertainment during the trip.

We mention below the special trains concerning which we have received information:

American Medical Special.—This luxurious Pullman train with full equipment will run from Chicago to Los Angeles via the Santa Fe and will leave Chicago at 8:00 p. m., Wednesday, June 21, reaching Kansas City at 9:00 a. m., Thursday, June 22, and running thence through New Mexico and Arizona to Los Angeles, which will be reached Monday, June 26, at 7:00 a. m. At Albuquerque the train will make a stop of an hour and a half to allow an inspection of the Fred Harvey collection of Indian handwork. Another stop will be made at Laguna, where an hour will be allowed to inspect the village of the Laguna Indians. The train will stop at the Grand Canyon for twenty-eight hours, giving opportunity to see the Grand Canyon of the Arizona. The desert of lower California will be crossed in the night. At San Bernardino the train will be divided—one section running through directly to Los Angeles, arriving at 7:00 a. m.—and the other going via Redlands and Riverside, stopping at each of these places to allow visits to points of interest. This section arrives at Los Angeles at 4:30 p. m., Monday. Special illustrated folders, reservations and full information may be obtained from G. T. Gunnip, General Agent, A. T. & S. F. Ry., 105 Adams Street, Chicago.

American Academy of Medicine Tour.—Another trip arranged from the east is that of the American Academy of Medicine, whose itineraries have been selected and arranged under the guidance of the passenger departments of the railroads to secure the most desirable trains and the best disposition of daylight sight seeing. Regular trains will be used. This party will leave New York over the Lehigh Valley railroad at 11:55 a. m., Monday, June 12, Philadelphia, at 12:30 p. m., and join the New York train at South Bethlehem at 2:12 p. m. and arrive at Buffalo over the Lehigh Valley at 10:27 p. m. The route will be thence over the Grand Trunk to Chicago, the Burlington to Denver and to Los Angeles over the Santa Fe. Interesting side trips and visits to the points of interest in Colorado and to the Grand Canyon will be provided for and Los Angeles will be reached Friday, June 23, in time for the sessions of the academy, which meets in advance of the American Medical Association. This party may be joined at various points along the route at a much later date, in case it is not desired to spend so much time on the going trip. Reservations for this party are to be made through the secretary, Dr. Charles McIntire, 52 North Fourth Street, Easton, Pa., from whom may be obtained the folder containing all details, both of the outgoing and of the return trip.

OTHER HOTELS ON THE MAP

9. Rosslyn. 10. Natick. 11. Nadeau. 12. Astoria. 13. Auditorium. 14. Percival Apts. 15. Broadway. 16. Yorkshire.

Burlington-Colorado Scenic Special.—This special train from Chicago to Los Angeles, via the Burlington, Denver & Rio Grande and the Salt Lake Route, will have the finest equipment of the Burlington road. It leaves Chicago at 11:00 p. m., June 21, and reaches Denver at 7:00 a. m., June 23. The party will spend four hours in Denver and vicinity, leaving at 11:00 a. m., June 23, reaching Colorado Springs (Manitou) at 1:30 p. m. The train will be parked and will remain there all night. This will give an opportunity for the party to go up Pike's Peak, visit the Garden of the Gods, Cheyenne Canyon, the celebrated "High Drive," the famous Iron and Soda Springs, and other points. The train leaves Manitou at 4:30 a. m., June 24, and reaches the Royal Gorge at 7:30 a. m., giving a splendid opportunity to see this wonderful gorge. At Glenwood Springs, an hour and a half will be spent, and Salt Lake City will be reached at 8:30 a. m., June 25. Four hours will be spent in Salt Lake, leaving at 1:00 p. m., and Los Angeles will be reached at 12:00 o'clock noon on June 26. This train traverses the mining regions of Utah and Nevada, and Rainbow Canyon and the Canyon of the Mojave River before reaching the orange country of southern California. This train has been arranged at the request of many physicians (represented by Drs. Robert T. Gillmore, Sidney Kuh and Charles B. Reed), who want to go by the Manitou and Royal Gorge route. Full details and illustrated booklets may be obtained from A. J. Puhl, General Agent, C. B. & Q. Ry., Chicago.

Chicago Medical Society Special.—The special train of the Chicago Medical Society will leave Chicago at 9:15 p. m., June 22, via the C. & N. W. Ry.; arrive in Omaha 9:15 a. m., June 23, leave Omaha 9:30 a. m., arrive in Salt Lake 1:30 p. m., June 24, spending the afternoon at Salt Lake, leaving at 5:30 p. m., June 24, via Salt Lake Route, arriving at Los Angeles at 4:30 p. m., June 25. This train will be provided with full Pullman equipment of the most complete and modern character. Meals in dining car will be served à la carte. At Salt Lake arrangements will be made for a special organ recital at the Mormon tabernacle, balance of the afternoon to be spent in sight-seeing. Leaving Salt Lake, the journey lies over the Salt Lake Route through Utah and Nevada, reaching the rich mining districts, passing through Caliente, where Rainbow Canyon is entered, with its great walls of rock of every shade; and Las Vegas. Entering California, the line traverses the canyon of the Mojave river and at San Bernardino reaches the famous Orange Belt of California. The train then runs through Riverside, Ontario and Pomona, cities situated in the fruit-growing section adjacent to Los Angeles. Arrangements have been made so that any physician anticipating telegrams en route will have same sent in care of this special train and be received promptly. Elaborate itinerary will be furnished on application to Dr. George F. Suker, Secretary, 103 State Street, Chicago.

Gates Special Train.—A special itinerary is being arranged by the Gates Tours of Toledo, O., with several optional return schedules. A special train will leave Chicago, June 20, stopping enroute at the Grand Canyon, and returning, trains will leave Los Angeles July 1. Full details of the trips, including the return schedules which include Alaska, may be obtained of the Gates Tours, Toledo, O.

Missouri Valley Special.—This special train, under the auspices of the Medical Society of the Missouri Valley and the Medical Association of the Southwest, will accommodate members from the central west and southwest. It will leave Kansas City Thursday, June 22, via the Santa Fe, and will also stop over one day for the trip to the beautiful Grand Canyon. It will arrive at Los Angeles on Sunday, after the trip through the orange country. The tour will be personally conducted and a special interesting itinerary is planned for the return trip. Full particulars may be obtained, and hotel and Pullman accommodations arranged for, through Dr. Charles Wood Fassett, St. Joseph, Mo.

New York and New England Special.—This is another train which has been planned in care of McCann's Tours by Dr. Wisner R. Townsend, Secretary of the New York State Medical Society. This train, fully equipped with modern conveniences and comforts, will leave New York, via the New York Central Lines, at 6:30 p. m., Monday, June 19, connecting with trains leaving Boston at 2:00 p. m., Worcester at 3:11 p. m., Springfield 4:40 p. m., and Pittsfield 6:30 p. m. It leaves Albany at 9:55 p. m., Utica 11:55 p. m., Syracuse 1:08 a. m., June 20, Rochester 2:45 a. m., Buffalo 4:30 a. m. The train will run thence via Cleveland, Indianapolis and St. Louis, and from Kansas City via the Santa Fe through New Mexico and Arizona, reaching the Grand Canyon, Friday, June 23, where twenty-eight hours will be devoted to sight seeing in this marvelous natural chasm, one of the wonders of the world. Los Angeles will be reached at 9:00 p. m., June 25. Time will be allowed to visit the famous orange groves and to view the other points of interest at Riverside and Redlands, as has been described above concerning the other trains. The return trip is one of some length and will include many other parts of the beautiful west which are to be enjoyed at leisure. Information concerning this tour and the daily schedule of the train, including the various possibilities on the return trip, may be obtained through Dr. Wisner R. Townsend, 125 W. 58th Street, New York City.

Pennsylvania Special.—From the east a personally conducted tour has been arranged under the direction of Dr. C. L. Stevens, Secretary of the Pennsylvania State Medical Society, Athens, Pa., in conjunction with McCann's Tours. The train will be of the highest grade Pullman equipment, including a gentlemen's club car and a ladies' club and observation car, with all the accessories and accommodations of the modern train *de luxe*. The special train will leave Jersey City Saturday, June 17, at 4:14 p. m., via the Lehigh Valley railroad, and may be joined at various points between there and Buffalo by passengers from New Jersey, eastern Pennsylvania and Maryland. The train will leave Buffalo via the Lake Shore at 4:30 a. m., June 18, running thence through Cleveland, Indianapolis, St. Louis, Kansas City, Santa Fe, and Albuquerque to the Grand Canyon, where a side trip of twenty-eight hours will be made. Thence the route will include the heart of the orange country in California, Riverside and Redlands, at both of which places time stops will be made. Los Angeles will be reached Friday, June 23, at 9:00 p. m. Full information concerning this tour is contained in a little booklet, which may be obtained from Secretary Stevens.

Eastern States Special.—Pullman cars to be attached to American Medical Special at Chicago over Santa Fe in care of Beekman Tourist Company, arranged by Dr. E. R. Campbell, manager of A. M. A. Outing Club, will leave Boston via Boston & Maine and New York Central Lines Tuesday, June 20, at 12:30 p. m., arriving at Chicago at 5 p. m. Wednesday, leaving Chicago at 8 p. m., joining American Medical Special. Members and friends may join anywhere en route. Special circulars, reservations, etc., may be obtained from Dr. E. R. Campbell, Bellows Falls, Vt.

RETURN TRIPS

As will be noted, several of these tours provide for the return trip by different routes, with interesting side trips. Full information about them can be obtained from the railroads or from the parties named above. In the advertising pages of The Journal, now and in later issues, will be found announcements of many of these railroads and trips. Members are urged to secure the booklets and folders issued by the railroads concerning these trips and post themselves in order to secure the greatest advantages from the visit to the west.

There are numerous ways of returning from the meeting, all of which offer advantages that will appeal to the members and their friends. The return trip from Los Angeles may be made by boat to San Francisco, Portland and Seattle, or by the southern routes over the Southern Pacific, the Rock Island, the Santa Fe, the Salt Lake route or through San Francisco by way of the Southern Pacific and Union Pacific, which offers opportunity for a side trip to the Yellowstone Park and a visit to Salt Lake and all the points of interest in Colorado. Or the return trip may be made by the northern routes—the Northern Pacific, the Chicago, Milwaukee and St. Paul, the Great Northern or the Canadian Pacific—visiting the cities of the northwest and Yellowstone Park.

PERSONNEL OF HOUSE OF DELEGATES

Membership of the Legislative Body of the Association

Below is a list of the holdover delegates and of the newly elected members of the House of Delegates, who have been reported to The Journal up to the time of going to press. A complete list is impossible in this issue as a number of state societies have yet to hold their meetings at which delegates will be elected.

THE GENERAL MEETING

Program of the Opeing Meeting on Tuesday Morning

The General Meeting will be held in the Baptist Auditorium, Fifth and Olive Streets, Tuesday, June 27, at 10:30 a. m. This is the formal opening of the scientific functions of the Association and the only time the whole convention will be assembled in one place. The program is as follows:

Music.
Call to order by President William H. Welch, Baltimore
Invocation by the Rt. Rev. Joseph H. Johnson, Los Angeles.
Addresses of Welcome.
Dr. W. Jarvis Barlow, President of the Los Angeles County Medical Association.
Dr. Thomas W. Huntington, San Francisco, President of the Medical Society of the State of California.
Hon. H. W. Johnson, Governor of California.
Hon. George Alexander, Mayor of Los Angeles.
Introduction of foreign guests.
Report of Local Committee on Arrangements—Chairman, Dr. H. Bert Ellis, Los Angeles.
Introduction and Installation of the President-Elect—Dr. John B. Murphy, Chicago.
Address by the President—Dr. John B. Murphy.
Music.
Adjournment.

CLASS AND COLLEGE REUNIONS

Miscellaneous Information Concerning the Western Country and the Trip to Los Angeles. Entertainment En Route

As is usual at the annual meeting of the Association, there will be a number of class and college reunions. The times and places of holding these will be announced at Los Angeles.

The reunion of the alumni of Cook County Hospital will be held on the evening of Friday, June 30, at the Casa Verdugo, a resort in the foothills a short distance from Los Angeles, reached by a trolley line. An old-style Spanish dinner will be served under the pepper trees. The reunion is in charge of Dr. W. W. Richardson and Dr. Harvey L. Thorpe. Los

Angeles. Information concerning this dinner may also be had from Dr. William R. Cubbins, 29 West Madison Street, Chicago.

The annual *woman's banquet* will be given at the Hotel Westminster, Tuesday evening, June 27.

The local chapter of Alpha Epsilon Iota fraternity will give *a dinner to visiting* members at the Union League Club, Thursday evening, June 29.

Arrangements have been made by the King County Medical Society at Seattle, Wash., in connection with the Seattle Commercial Club, for a committee to entertain the members of the American Medical Association who may pass through Seattle on their way to attend the meeting or on their return.

The Riverside County Medical Society also invites all physicians to visit Riverside, take the 16-mile auto ride through the orange groves and enjoy the courtesies provided.

At Los Angeles the Chamber of Commerce maintains an interesting museum of the products of California and the West, both mineral and agricultural. Practically the whole state may be seen in picture form at these lectures.

OTHER MEETINGS

Among the other scientific meetings which may be attended by members and vistors to the Los Angeles meeting of the A. M. A. are the following:

The convention of the National Association for the Study and Prevention of Tuberculosis, which meets at Denver, June 20 and 21. Stopovers will be allowed at Denver, as well as at other points, on the going trip to Los Angeles, and the meeting of the Tuberculosis Congress may be attended, and then the special trains running through Denver may be joined for the remainder of the trip. Information may be had from Dr. Livingston Farrand, 105 East Twenty-Second Street, New York.

The American Academy of Medicine will hold its sessions in Los Angeles on Saturday and Monday preceding the meeting of the A. M. A. For full information address Dr. Charles McIntire, 52 N. Fourth Street, Easton, Pa.

The annual meeting of the American Medical Association Public Health Education Committee will be held in the Y. W. C. A. Building, 251 S. Hill Street, Los Angeles, Monday, June 26, at 5 p. m. Particulars and program may be obtained from Rosalie Slaughter Morton, M.D., Chairman, 701 Madison Avenue, New York.

The twelfth annual session of the American Association of Medical Examiners will be held at Los Angeles, June 26 and 27, 1911. Information may be obtained from Dr. Liston H. Montgomery, president, 108 North State Street, Chicago.

Floor plan of the Hamburger building, fourth floor, showing the location of the Registration Bureau, where each member should register as soon as he can name his hotel; also the Postoffice, Scientific Exhibit, Daily Bulletin office and the Commercial Exhibit. The accompanying list shows what firms will occupy the various numbered spaces.

THE COMMERCIAL EXHIBIT

Outlook for an Interesting Exhibit of Distinct Quality

The commercial exhibit at the Los Angeles meeting will be found in Hamburger's hall on the fourth floor of the Hamburger Building at Eighth Street and Broadway. In this commodious and well-lighted room will be found an exhibition of books, surgical instruments and appliances, *x*-ray and other electric apparatus, and of pharmaceutical preparations and foods, which, while it may not be as large as the exhibits at some of the eastern meetings of the Association, will be of high quality.

Efforts will be made by all of the exhibitors at this meeting to demonstrate their various exhibits rather from the scientific side than from the purely commercial aspect, and the demonstrators of the scientific apparatus, drugs, etc., will be men who are experts in their respective lines. The exhibit will, therefore, have a distinct educational value to physicians who will devote some time to it.

All correspondence with reference to reservations should be sent to Mr. Will C. Braun, superintendent of exhibits, 535 Dearborn Avenue, Chicago. Dr. W. H. Kiger, Consolidated Building, Los Angeles, is the chairman of the Los Angeles committee on commercial exhibits.

The accompanying diagram of the exhibit hall shows the locations of the booths. The following firms will be represented at this exposition. Other reservations have also been made by firms who have not submitted descriptions of their exhibits.

Publishers and Books

D. APPLETON & CO., NEW YORK, SPACE 2.—This exhibit will be under the direction of the manager of the San Francisco office and a competent corps of salesmen who will show the new editions. A work which will excite interest is their "Cross Section Anatomy," by Dr. Albert C. Eycleshymer of St. Louis. Other publications are Dieulafoy's "Practice of Medicine;" Pick and Hecht's "Clinical Symptomatology;" Kolle's "Plastic and Cosmetic Surgery;" Reik's "Diseases of the Ear, Nose and Throat," and a new edition of Pusey's "Dermatology." The above mentioned books have all been published since January 1, 1911. They will also show advance sheets of Guiteras' "Urology," and Kelly's "Diseases of the Kidneys."

AUSTIN'S STEREOSCOPIC X-RAY ANATOMY, SAN DIEGO. SPACE 11.—A collection of carefully selected life-size stereoscopic *x*-ray pictures, mounted on cards 12 by 17 inches, each of the pair being 8 by 10 inches, taken with the most modern of interrupterless machines, of all the normal joints, of the joints during development, of all the arteries injected, of the cavities, and parts of the intestines, being an anatomy at a glance for student and practitioner. Pictures are viewed through a prism stereoscope (making pictures of this size possible), mounted, so as to change without changing the focus.

P. BLAKISTON'S SON AND CO., PHILADELPHIA. SPACE 58.—Among the books of great interest and sound service at Blakiston's exhibit are: Hurry's "Vicious Circles," Collins and Mayou's "Pathology of the Eye," Eden's "Gynecology," the recent editions of Tyson's "Practice," Wilcox's "Treatment," "Practitioners' Medical Dictionary," J. J. Kyle's "Ear, Nose and Throat," Wiley's "Foods and Their Adulteration," Brophy's "Oral Surgery," Bransford Lewis and E. G. Marks' "Cystoscopy," and a translation of Curschmann's "Nervous Diseases," edited by Charles W. Burr. The splendid works by John B. Deaver should attract attention because of his recent recall to the professorship in the University of Pennsylvania.

Wappler Electric Mfg. Company. Spa PHIA. Space .88.—

Dr. L. A. Duck will be in charge.

Rebman Company, New York. Space 12.—An assortment of highly scientific books, many of which are illustrated by the four-color process, which renders a life-like appearance of diseases, especially those of the skin, possible, and the latest literature on "Salvarsan" will be found. Of interest is Whitby's "Makers of Man," a psychologic study of the individuality of the great men of the world. A book on an entirely new subject is Kilner's treatise, "Human Atmosphere." A long list of new publications by Rebman Company recently will be on view, which it will pay the visiting physician to enquire about. Their art prints are worthy of attention.

W. B. Saunders Company, Philadelphia and London. Spaces 94 and 95.—Just within the entrance and opposite the Bureau of Registration and Information and the Post Office, this house will exhibit Musser and Kelly's "Practical Treatment;" Cabot's "Differential Diagnosis;" Davis' "Operative Obstetrics;" "The 1910 Papers by the Staff of St. Mary's Hospital, Mayo Clinic;" Anders and Boston's "Medical Diagnosis;" Morrow's "Diagnostic and Therapeutic Technic;" Pilcher's "Practical Cystoscopy;" Buchanan's "Veterinary Bacteriology;" Keen's "Surgery;" Mumford's "Surgery;" Crandon's "Surgical After-Treatment;" Cotton's "Dislocations and Joint Fractures;" Sisson's "Veterinary Anatomy;" also advance sheets of Dr. Howard A. Kelly's "Cyclopedia of American Medical Biography."

William Wood & Co., New York. Spaces 3 and 4.—Have spared no expense in exhibiting their high-class medical books. Noteworthy among these is the "American Practice of Surgery," which has just been completed. An epoch-making book is Steadman's Medical Dictionary. Witthaus' Manual of Toxicology has just issued from the press. Also, a revised edition of Walker's Introduction to Dermatology, containing forty-three colored plates, besides numerous engravings. "Joint-Tuberculosis," by Leonard W. Ely, will attract much attention. In addition to the above, one hundred new books by these publishers attest their continued activity and progressiveness.

Pharmaceuticals and Biologic Products

Abbott Alkaloidal Company, Chicago. Spaces 56 and 57.—The special features of the exhibit of this company will be the demonstration of the methods of manufacturing granules and tablets of the active-principle and similar remedies by skilled laboratory workers, illustrating both the hand and machine methods. In addition this company will present a large line of alkaloidal and active-principle remedies, as they extract them from the drugs and in finished forms. Their interesting line of Council-passed specialties will also be demonstrated.

Arlington Chemical Company, Yonkers, N. Y. Space 1.—Will be occupied jointly by the Arlington Chemical Co. and the Palisade Manufacturing Co., makers of liquid and dry peptonoids and hemaboloids. In accordance with the well-known policy of these manufacturers there will be a display of interesting and instructive charts of food values, together with an exhibit of the various constituents of the preparations. Courteous and capable representatives will be ready to explain the preparations and answer any questions regarding them. A handsome souvenir is in preparation, which will be presented to every physician who visits the exhibit.

Armour & Co., Chicago. Space 93.—Remarkable progress has been made in the last decade in the field of the ductless glands, which are gradually yielding their therapeutic secrets to the industry of the experimental biologist. Brilliant results are now obtained by pure suprarenal preparations and the purified thyroid proteids. Hypersecretion of the pituitary is definitely known to result in acromegaly and gigantism. Recently the thymus has been suggested for relief in inoperable cancer. Many lecithins and organ lipoids apparently play an important rôle in immunizing processes. The organotherapeutic exhibit of this firm will be demonstrated by scientific experts and should be of great interest.

Edward G. Binz, Los Angeles. Space 22.—This display will consist of apparatus in full operation, showing the process of distilling and refining eucalyptus oil from the leaf to the finished oil. It will be a demonstration of the production of a superior pharmacopeial product and not of a proprietary article with a trade name.

Burroughs Wellcome & Co., New York. Space 54.—This firm will display a selection of their products under "Tabloid," "Soloid," "Vaporole," "Enule," "Wellcome," and other of their well-known trade-marks, representing modern methods as applied to medicinal preparations. Also "Tabloid" brand compressed surgical dressings and bandages, including "Tabloid" brand bismuth gauze, a recent addition to the firm's list; medical equipments of extreme compactness and portability, ranging in size and scope from the equipment similar to that carried by many well-known explorers, to a physician's breast pocket case; "Tabloid" hypodermic and ophthalmic pocket cases, including the popular "Mussell Shell" hypodermic case, etc.

Cutter Laboratory, Berkeley, Cal. Space 82.—Serum Antitoxin and Globulin Antitoxin will be displayed by this firm; also their syringe containers with flexible needle connection. An interesting demonstration showing the steps employed in the preparation and data respecting the administration of the various antitoxic products will make this exhibit of unusual scientific value.

Fairchild Bros. & Foster. Space 98.—Will exhibit "ampoules" for hypodermatic injection, trypsin, pancreas extract (non-enzymic), lecithin; capsules especially designed for the administration of pancreas gland products; "Laibose," soluble wheat and whole milk in granular form; Fairchild's culture peptone from entire beef, especially prepared for bacteriologic work.

Hoffmann-La Roche Chemical Works, New York (branch of F. Hoffmann-La Roche & Company, Basle, Switzerland, and Grenzach, Germany). Space 37.—This exhibit will repay careful inspection. A duplicate of the exhibit that was made at the St. Louis Convention, when it was declared one of the most "aristocratic" in the building. Here will be found such alkaloids as homatropin, eserin, pilocarpin, hyoscin and a host of others. The specialties, Digalen, Thiocol, Thigenol, Airol, Secacornin, etc., will be exhibited and their therapeutic qualities explained by competent representatives.

H. K. Mulford Company, Philadelphia, Space 92.—Will exhibit five cases of biologic products containing, respectively, diphtheria antitoxin and serums, bacterial vaccines and tuberculins, diagnostic reagents, including serodiagnosis of typhoid fever and syphilis; rabies vaccine, and Neisser bacterin, mixed. The exhibition will also comprise working bulletins describing these products.

Henry K. Wampole & Company, Philadelphia. Space 76.—This company will make an exhibit of elegant pharmaceuticals, comprising pulverous pills, compressed tablets, fluidextracts, elixirs, effervescent salts, capsules, etc., and direct especial attention to the new things brought out during the past year, and to its ability to produce efficient and elegant products for the physician.

Instruments and Furniture

W. D. Allison Company, Indianapolis. Spaces 102 and 103.—Have added several new and useful tables and cabinets to their line, and will have on display a new style, medium-priced table, two new and very attractive designs in instrument cabinets, and being now the owners of the patents on the Yale and Oxford chairs, these articles will be presented in connection with their high-grade automatic tables, medicine and instrument cabinets and specialities. All of these have, been proved indispensable appliances in the practice of medicine during the past twenty-five years.

FRANK S. BETZ CO., CHICAGO AND HAMMOND, IND. SPACES 62, 63, 64 AND 65.—This company will make an exhibition of a general line of surgical instruments, special razor-operating knives manufactured by experienced razor makers, nose and throat instruments imported from Vienna, also *x*-ray coils, electrical outfits for general and diagnostic purposes and a variety of artificial legs. The special feature of the exhibit will be the great variety of operating knives, among which will be shown the Mayo, Murphy, Cubbins, Weist and Old-English models.

CAVASCOPE CO., ST. PAUL, MINN. SPACE 8.—This company will exhibit the Cavascope, which combines an auriscope, a nasal speculum and two styles of tongue-depresser. It is self-illuminated from a dry battery, which may be obtained anywhere, an effective one being the Tungsten battery, which will give 400 per cent. greater service than any other. The instrument is easily sterilized and may be carried in the pocket.

F. A. HARDY & COMPANY, CHICAGO. Space 89.—A complete line of eye, ear, nose and throat surgical instruments as well as a number of ophthalmologic specialties will be exhibited. The special features of this exhibit will be a number of hand-made instruments entirely new in design, surpassing anything ever shown heretofore. The special Los Angeles edition of the "Hardy Messenger" will illustrate each of the new designs and will be distributed at the exhibit.

KENISTON AND ROOT, LOS ANGELES. Spaces 90 and 91.—A general line of standard surgical instruments, physicians' office equipment and hospital supplies will be demonstrated and displayed by this firm. In this exhibit will be included that of the Kny-Scheerer Co., of New York City.

E. B. MEYROWITZ, NEW YORK. Spaces 48, 50 and 51.—Ophthalmologic apparatus, eye, ear, nose and throat instruments embracing many recent inventions, among which may be mentioned a new model of ophthalmometer, Yankauer's eustachian instruments, a full line of bronchoscopic instruments and illuminating apparatus will be found. This firm manufactures and will show the well known Marple electric ophthalmoscope, Coakley electric light stand and the Meyrowitz socket rheostat. The new Meyrowitz-McCaa unipulsator will be shown, a complete instrumentarium for *x*-ray and high-frequency work.

PACIFIC SURGICAL MANUFACTURING CO., LOS ANGELES, CAL. Space 19.—A complete line of physicians' apparatus and hospital equipment and supplies will be exhibited by this company.

Apparatus

ANATOMIK FOOTWEAR COMPANY, NEW YORK. SPACE 78.—An exhibit of men's, women's and children's Anatomik shoes for the relief of mild cases of flat foot and for the prevention of foot troubles. Anatomik shoes are made on a special last devised by Dr. Harlan P. Cole of New York. Mr. Alick Weir, in charge of the exhibit, will be glad to explain the features of the special shoes made by this company for bad cases of flat-foot and for various forms of talipes.

BAUSCH & LOMB OPTICAL CO., ROCHESTER, N. Y. Space 79.—They will show a line of their newest models of microscopes, microtomes, centrifuges and other laboratory apparatus and supplies for physicians' use. A new instrument, a convertible balopticon will be shown, which projects lantern slides, opaque illustrations and objects and microscopic objects; in fact it can be used for any known form of projection. It will be especially appreciated by those interested in the projection of microscopic objects.

DEVILBISS MANUFACTURING COMPANY, TOLEDO, O. SPACE 15.—The use of the atomizer in the treatment of nose and throat affections will be interestingly covered in the complete exhibit of the DeVilbiss Manufacturing Company of Toledo, O., who will have on display a full line of their well-known medicinal atomizers, nebulizers and powder blowers.

DUNTLEY MANUFACTURING CO., CHICAGO, SPACE 81.—This exhibit will consist of the Duntley pneumatic cleaner, and the new Duntley air cooler and purifier. The latter is a little device with a capacity of from 200 to 600 cubic feet of air per minute. The air passing through water, is cooled and purified, and all of the floating matter is removed—thus reducing the danger of infection in operating rooms and hospitals. The firm will exhibit two types of the air cooler and purifier. The exhibit will be in charge of Dr. Carl L. Barnes, who will gladly furnish laboratory reports and descriptive circulars to all physicians who may be interested.

WILMOT CASTLE COMPANY, ROCHESTER, N. Y. SPAC
This company will exhibit a four-piece Rochester sterilizing outfit, "physician's" size, comprising an instrument sterilizer, a dressing sterilizer and hot and cold water sterilizers. Instruments are sterilized by boiling; dressings by circulating steam; also a three-piece outfit of a smaller size, called the "Specialist's," adapted for eye, ear, nose and throat work. A Castle pressure dressing sterilizer will show the separate generator, the complete surrounding of the sterilizing chamber (except in front) by a steam chamber, the single valve control, the production of a vacuum in the sterilizing chamber and the simplicity and effectiveness of its locking device.

Apparatus—Electric

ELECTRO-SURGICAL INSTRUMENT CO., ROCHESTER, N. Y. SPACE 5.—In addition to a complete line of all its well-known electrically lighted surgical instruments the company will exhibit a number of new instruments, representing the highest present development of electrically lighted surgical and diagnostic instruments, constructed after the designs of eminent specialists, who have taken particular interest in making suggestions for improvements based on their practical experience. Besides the instruments themselves the exhibit will include the latest forms of batteries, controllers and transformers.

KELLEY-KOETT MFG. CO., COVINGTON, KY. Spaces 68 and 69. —This company will make a demonstration of their *x*-ray appliances under the direct supervision of Mr. J. Robert Kelley, designer and senior member of the firm, who extends a cordial invitation to the profession, especially those of the Pacific Coast, and past patrons who may desire information relative to apparatus already in use.

ROCHESTER SURGICAL APPLIANCE COMPANY, ROCHESTER, N. Y. Space 17.—These makers of electrically lighted instruments, will exhibit their latest models for use as diagnostic aids in the examination of affections of the nose, throat, esophagus, urethra, etc. Instruments for transillumination tests, also electrical controllers, etc., will be other noteworthy features.

SCHEIDEL - WESTERN X-RAY COIL CO., CHICAGO. SPACES 29 AND 30.—Will have an unusual scientific display of advanced apparatus for making *x*-ray negatives and diagnoses by the most approved methods. The increased popularity of the *x*-ray for diagnosis and the attention given to improved technic has resulted in wonderful improvements. They will demonstrate the latest interrupterless machine with which the fastest negatives, showing detail, have ever been made, and in addition to this their small portable instrument. The former radiographic special will also be there, as well as a stereoscope, plate changer, *x*-ray protection tube-stand, etc.

VICTOR ELECTRIC COMPANY, CHICAGO. SPACES 32, 33, 34 AND 35.—This company will display between seventy-five and one hundred different pieces of electro-medical apparatus, which will be demonstrated by a corps of experts. The past year has brought out many new developments in physiologic therapeutics in the way of new machines, modernized methods, improved technic, etc. The Victor Electric Co. have had to increase their facilities recently by erecting a new building at Jackson Boulevard and Robey street, Chicago, which they are now occupying.

Pediatrics;" new ll exhibit their Malted Milk and call particular
peutics;" Beck's " the special process by which it is prepared and
tions;" Longy gestion of the casein of the milk due to this process,
worm Disea is peculiar to the Borden Company. They also empha-
of the N size the palatability of the food, it being free from excessive sweetness. They point with pride to their record of fifty years' handling of milk products as a guarantee of the excellence of their goods. They will furnish analysis and comparative table of energy values to all physicians.

FRANCO-AMERICAN FOOD CO., JERSEY CITY. SPACE 36. —Franco-American broths for invalids will be shown as a useful necessity in the sick room diet, easily digested and very stimulating. The company calls attention to these broths as containing 33⅓ per cent. more food value than soups, purposely made without vegetables, spices or seasoning, and retained by the most delicate stomach. They are packed in half pint sanitary tins, so as to remain fresh as long as the tin is left unopened. A full line of these foods will be exhibited.

HAWAIIAN PINEAPPLE PRODUCTS CO., LTD., SAN JOSE, CAL. SPACES 23 and 24.—Physicians will be given an opportunity to investigate the merits of Dole's Pure Hawaiian Pineapple Juice, which is pressed and bottled by this firm in Honolulu.

HORLICK'S MALTED MILK CO. SPACES 72, 73, 74 AND 75.—This firm will show Horlick's Malted Milk and urge its use as an easily digested food product in powder form, prepared from pure fresh cow's milk, combined with the extracts of malt, barley and wheat, the starch of which has all been converted by the action of the diastase of the malt, and ready for immediate use by simply dissolving in hot or cold water; uniform and reliable, manufactured under ideal sanitary conditions, with the experience, methods and apparatus evolved through work of over a century in this line.

MELLIN'S FOOD COMPANY, BOSTON. SPACE 14.—To the visiting physicians who so desire this company's representatives will be pleased to show analyses and food values of Mellin's Food itself, and as prepared with milk; also to explain its use in the modification of milk. They will also cheerfully answer questions regarding the variation of proportions of food constituents necessary to obtain the most satisfactory results in individual cases.

WELCH GRAPE JUICE COMPANY, WESTFIELD, N. Y. SPACES 66 and 67.—Will have an exhibit of their well-known product, as usual.

Artificial Limbs and Supportive Appliances

AMBULATORY PNEUMATIC SPLINT MANUFACTURING CO., CHICAGO. SPACE 10.—Makers of ambulatory pneumatic fracture splints, orthopedic appliances, artificial limbs, trusses, corsets, elastic hosiery and "Ambumatic" washable abdominal supporters. Under the direction of Mr. Sæmann the exhibit will consist of a scientific demonstration of the Ambulatory Pneumatic Splint, the application and use of these walking adjustable splints for the comfortable and successful treatment in bed or walking of fractures of the lower limbs, including those of hip and hip-joint disease. "Ambumatic" supporters for all kinds of abdominal or pelvic support will also be shown.

CARNES ARTIFICIAL LIMB COMPANY, KANSAS CITY, MO. SPACE 59.—Will exhibit an artificial arm and hand made of steel and fiber of such ingenious mechanical construction as to enable the wearer automatically to bend the elbow, bend and turn the wrist and open and close the fingers, and write; strong enough to pick up and carry a weight of fifty pounds with ease. Demonstrated by men wearing the arm for upper and lower amputations.

WM. JONES, DENVER, SPACE 9.—An automatic, adjustable truss will be demonstrated by this firm. This truss is s to have an automatically operating, even pressure, comp sating movement that is governed by the motion of the bo so that it will yield reciprocally with easy, positive, varia and equal pressure action to the variable breathing and ot natural movements of the body. There are many other pr tical features of this appliance that will be shown.

Mineral Waters

APOLLINARIS AGENCY COMPANY, NEW YORK. SPACE 7 This company will exhibit Apollinaris Water as a mildly al line and naturally effervescent table water, bottled only at Apollinaris Spring, Neuenahr, Germany, and only with own natural gas, as stated on the label. The same compa will also exhibit "Apenta," the Hungarian natural aperi water, calling attention to its reputation for its well prop tioned content of magnesium sulphate and sodium sulphate.

NATIONAL WATER COMPANY, WAUKESHA, WIS. SPACE 38. Will exhibit "White Rock," the natural water from t celebrated White Rock Spring, and "Still Rock" in the vario sized bottles and will show a package that is unique amo bottled waters. New bottles are used and are sterili before filling. The newly patented sealing contrivance w prove interesting to the physician who wishes to have t water reach his patient in the same uncontaminated conditi in which it exists as it flows from the spring. Mr. Edwa Westveer and Mr. R. M. Heath will have charge of t exhibit.

Sanatoria

ALLIED SANITARIUMS OF CALIFORNIA, LOMA LINDA, CA SPACE 25.—This exhibit will be installed under the dire tion of the College of Medical Evangelists, whose represent tives will explain the methods employed at their vario institutions.

INDIANA SPRINGS CO., KRAMER, IND. SPACE 20.—For t benefit of physicians who have never visited Mudlavia th company will maintain an exhibit showing in pictorial det their special therapeutic agent, the Mudlavia Bath. Begi ning with a view of the mud deposit in the natural state, t various steps in the process to completion of the bath will shown; likewise the buildings and grounds with their speci equipment for maintaining a high-grade sanitarium.

POTTENGER SANATORIUM, MONROVIA, CAL. SPACE 25.—Th institution, which is located but forty-five minutes by troll ride from Los Angeles, and is conducted exclusively for t scientific treatment of tuberculosis, will display views an literature describing the methods employed and accommod tions offered patrons of their sanitarium.

Et Cetera

AMERICAN CASE & REGISTER COMPANY, SALEM. SPAC 86.—Will exhibit a full line of their physicians' and surgeon systems for account keeping and case recording. This exhib will be in charge of competent men who have been traine especially in this line of work. They claim to be the pionee in manufacturing complete physicians' and surgeons' system and they wish physicians to write now for all literature per taining to their various systems so that they can study then up, and then see the real article in Booth 86.

DEIMEL LINEN-MESH SYSTEM CO., NEW YORK. SPACE 53.—According to their usual custom this company will show thei goods at Los Angeles and have reserved space 53 for the pur pose. The California headquarters of this concern is at 14 Sansome Street, San Francisco. The Dr. Deimel underwea (Linen-Mesh) hardly needs any introduction. This well-known underwear was first shown at the annual meeting held at Baltimore in 1895.

SPIRELLA COMPANY, MEADVILLE, PA. SPACE 85.—Corsets and belts filled with the "Spirella stay," a wire bent in serpentine form, will be shown as a valuable aid in caring for medical cases demanding support, such as floating kidney, some cases of hernia and pendulous abdomen. The firm states that the anatomic shaping of the corset, coupled with the flexible, resilient Spirella stay used therein, allows complete freedom of muscular action. The Surgical Belts are light, simple, practical, and are said to be valuable in postoperative cases.
